THE publication of Dr. Ewing's book followed upon its being accepted by the University of Oxford for the doctorate in philosophy. The plan of the work is twofold. In the first place, Dr. Ewing has written a work on one of the Categories of Kant in isolation from the whole, and, in the second place, he has endeavoured to elaborate and correct Kant in such a way as to present before the reader a restatement of Kant's proof in a form in which it can stand by itself and make a good claim on all schools of thought." The former plan, naturally, being less pretentious, is carried out with more success than the latter, although the author's strong insistence on certain fundamental aspects of causality may, on further elucidation, "work the trick."

As a student of Kant, the author shows gifts of understanding and knowledge which must be unique in so young a student, and his insistence on the metaphysical interpretation, as opposed to the merely psychological, in the transcendental deduction and the analogy, and his strong insistence on the teleological aspect of Kant's late works, show him to possess a mind which reads and criticises freshly and a firm belief in his own powers of interpretation. In this part of the work, all students of Kant will find real interest and fresh enlightenment. We fear, however, that his hope that Kant can be restated in such a way as to prove causality is rather sanguine, and we are unable to follow his startling contention that we have direct synthetic *a priori* knowledge in some of our psychic states. His insistence on the "must" in causal laws will also draw protest from certain schools of thought, although it is time that the necessity was again pointed out, and we are glad that Dr. Ewing has had the courage to do it. The work can be thoroughly recommended to all students of philosophy.

Behind and Before: Two Essays on the Relation of History, Politics and Eugenist Warnings. By W. E. Heitland. Pp. xv + 166. (Cambridge: At the University Press, 1924.) 6*s.* net.

MR. HEITLAND, of St. John's College, Cambridge, has written a short but very thoughtful and suggestive book, mainly on the question of how far we may argue from history as to our action in the present and its results in the future. In general, he admits the possibility, and then proceeds to enforce the urgency of the study. But the bulk of his essay suggests various cautions and raises numerous problems. In particular he emphasises the need of distinguishing the behaviour of mankind in masses and groups from that of the same persons taken as individuals. This is, of course, the fundamental principle, in fact the *raison d'être*, of sociology. He also holds that if lessons are to be learnt from history as an equipment for practical politics, it is in the experience of recent times that they must be chiefly sought. This again is now a dominant principle in the school teaching of history, and it is thought by many people that the pendulum has swung too far in the direction of modernity.

There is no main thesis in the book which the author is concerned to defend as a new gospel, but he inspires a salutary sense of the importance of social biological study and drops many wise hints on the way. "A searching test," he tells us, "of the soundness of our civilisation is the frank and loyal acceptance of the consequences of our own imperfection." He is emphatic on the need of leadership, but avoids the common eugenic fallacy that the good stocks, which should naturally lead, are being bred out and swamped by inferior material. "What evidence is there," he asks, "that men risen from the ranks do lower the moral of the governing class?" Do not their better elements produce citizens of high quality, sometimes of distinguished merit? Do not they add strength to the governing classes? And where did these upper classes come from? A very interesting and well-balanced book. F. S. M.

The Nature of Art: an Open Letter to the Professor of Poetry in the University of Oxford. By Prof. J. A. Smith. Pp. 32. (Oxford: Clarendon Press; London: Oxford University Press, 1924.) 2*s.* net.

PROF. SMITH'S Open Letter is one of those delightful attempts to place before a brother professor a little of the knowledge which, although belonging more properly to the sphere of the writer's particular branch of learning, ought to be shared by his confrère. The letter was not written for publication, and, for that reason, is all the more delectable, for it shows a spirit of true learning, willing co-operation, and kindly friendliness which, in these days of commercial antagonism, is all the more refreshing. The preface tells us that after a discussion with the professor of poetry at Oxford, Prof. Smith desired further to explain his own position with regard to the nature of poetry and art and took the opportunity of doing so in this letter. That we have the privilege of reading it is due, apparently, to the impression that the letter made on the recipient. We do not know whether the sender made a convert, but the present writer, for one, is heartily

glad that the letter has been published. The aim of the letter is primarily to explain the theory of art which Prof. Smith himself holds. He points out that any criticism of art requires a ground for criticism, and that this, again, requires a theory. The writer holds such a theory and begs leave to present it to his friend. The theory is not his own, but that of a master, but he holds it none the less sincerely for that and hopes that it is, first, intelligible and, secondly, acceptable. The theory is, of course, that of Gentile, and the letter is a clear exposition of the Italian master's views on art. This we refrain from criticising, but we admire and commend both the matter of the letter and the spirit which prompted the writing of it. Those who have any interest, either in letters or art, will thoroughly enjoy the reading of it.

An Introduction to the Study of Heredity. By Prof. E. W. MacBride. (Home University Library of Modern Knowledge.) Pp. 256. (London: Williams and Norgate; New York: H. Holt and Co., 1924.) 2*s.* 6*d.* net.

OUR knowledge of heredity has long since passed the stage when it could be summed up in a few simple aphorisms such as "like begets like." During the past thirty years especially, many diverse lines of approach have been explored; biometry has attempted the measurement of likeness, cytology and experimental embryology have unveiled some of the mysteries of begetting, and Mendelian research has given one answer to the question why like sometimes begets unlike. To sketch an intelligible outline of the results obtained in these varied fields and to present them in ordered and logical sequence is no light undertaking; to compress it within the space of 250 pages might well seem impossible. Prof. MacBride, however, is an experienced teacher, with a gift for lucid and forcible exposition, and this little book is well fitted to arouse interest and to stimulate the reader to further study.

In such a survey it is impossible, even if it were desirable, to avoid some degree of dogmatism, and Prof. MacBride maintains his own point of view with vigour and occasionally with a touch of asperity. Some may think that he gives too easy credence to the claims of the Vienna school, or that he overestimates the adequacy of Tornier's hypothesis of "germ weakening" to account for the origin of mutations, and specialists in various fields will doubtless detect minor inaccuracies. It is a little difficult to reconcile the statement on the last page, "The study of biology teaches unequivocally that all progress in the animal world has been brought about by natural selection," with the tenor of some earlier passages, notably on page 138.

Entdeckte Verborgenheiten aus dem Alltagsgetriebe des Mikrokosmos. Von Prof. Dr. Paul Lindner. Pp. viii+291. (Berlin: Paul Parey, 1923.) 6*s.*

PROF. LINDNER'S book is a comprehensive treatise on a great variety of sciences that require the microscope as their principal instrument of research. It deals in a discursive way with the structure of the eye, the history of the microscope, the manufacture of leather, the brewing of beer, as well as with the biology of t common microscopic animals and plants, and wi many other topics. As might be expected in a bo of such wide scope, the quality and treatment of the subjects dealt with is not consistently good. Ma readers will be glad to have in a convenient abbreviat form the results of the distinguished author's searches on the fermentation processes, and the chapt dealing with the biology of wine making, of brewin on the bacterial decomposition of the food in t alimentary canal, on the formation of honey dew, a many other examples of interesting symbiotic relatio between animals and plants, are all excellent.

In other chapters the information given in the te is not trustworthy. The larvæ of the ox warble are not transferred from the legs to the œsophagus the tongue as stated on p. 259, but, as proved Carpenter, penetrate the skin and find a passa through the tissues to the alimentary canal. T principal cause of infestation by miners' worms (A chylostoma) is not by drinking polluted water. T names of some of the most prevalent parasites ar pests need revision. There is no justification, example, for the retention of *Distomum hæmatobiu* and *Musca vomitoria*, for the Bilharzia parasite and t blow-fly respectively. Many of the figures in the te are so small and so badly printed that they are mi leading instead of helpful to the reader.

Ordnance Survey Professional Papers. New Serie No. 7. *Air Survey and Archæology.* By O. G. Crawford. Pp. 39+13 plates, 5 diagrams+2 map (Southampton: Ordnance Survey Office; Londor H.M. Stationery Office.) 5*s.* net.

IN recent years field archæology has received a unexpected but very valuable addition to its apparat of investigation, in the shape of air-photography. suitable country, especially in the down land of southe England, we can look through the veil of the past an see on the air-photographs the dim traces of a lon vanished race; we can detect the lines of fiel boundaries and lynchets, of roads and earthwork all invisible to an observer on the ground. It is show by Mr. Crawford, in the volume before us, that n only can the features above indicated very often discovered by means of photography, but also tha it is possible to draw from the photographs importa inferences as to the relative ages of the earthwork Mr. Crawford deals particularly with the period Celtic occupation of England, which may, in his opinio have begun about 450 B.C., and, no doubt, lasted unt the final disappearance of the Romans about A.D. 45 An examination of the air-photographs shows a networ of field boundaries, banks and roads associated wit upland villages; some of these were certainly existence at the coming of the Romans, and som certainly persisted until their departure.

All who are interested in the history of rural Englan during this long period of some thousand years wi find this publication well worth studying; it is admi ably produced and illustrated, and incidentally show the reconstruction, from air-photographs, of th eastern branch of the Stonehenge Avenue leading dow to the river Avon.

Power Station Efficiency Control: a Treatise for the Power Station Engineer on Boiler-Room Efficiency, Turbine-Room Efficiency, Heat Balance Control, Methods of Recording and Tabulating Operating Results and Keeping a Day to Day Check on Operating Efficiency. By John Bruce. With an Appendix by R. H. Parsons. Pp. xiii+244. (London: Sir Isaac Pitman and Sons, Ltd., 1924.) 12*s.* 6*d.* net.

In the management of the boiler-house of power stations, great improvements have been made in recent years, with a consequent increase in the over-all efficiency of generation. All the coal used is now weighed with high accuracy. The temperature of the furnaces and of the flue gases is recorded and chemical analyses of the products of combustion are continually being made. The results are recorded, tabulated, and suitably analysed. The staff are always striving to improve their methods and are always ready to consider the possibilities of new inventions and of new fuels. Six years ago, the ratio of the heat equivalent of the kilowatts generated to the heat equivalent of the fuel consumed was commonly only about 10 per cent. To-day, thanks to scientific investigations, there are power stations in various places with a thermal efficiency of more than 18 per cent. Most of the improvement is due to increased efficiency in the boiler-house. The author asks the reader to look on this book as addressed to power station operating engineers, and states that it is not a highly technical treatise but a general talk on the salient factors influencing efficient operation. We can recommend the book to both students and engineers, as it gives a good introduction to many problems which engineers are successfully solving.

The Microscope. Part 2. An Advanced Handbook: a Sequel to "The Microscope, a Simple Handbook." By Conrad Beck. Pp. 231. (London: R. and J. Beck, Ltd., 1924.) n.p.

This book may be regarded as an advanced supplement to the author's simple handbook on the microscope, already noticed in these columns. It deals in particular with the optical theory of the microscope and on somewhat novel lines. What we would especially commend is the manner in which the reader is carried on from point to point with the use of simple geometrical diagrams and without reference to advanced mathematics.

In addition to the general optics of lenses, excellent chapters are introduced on microscopic photometry, resolution, and illumination. In the last named, dark ground illumination is dealt with and details are given of the Barnard special illuminator which permits of the use of objectives up to 1·27 N.A. In Chapter viii. various microscopes for special purposes are described, *e.g.* measuring, tank, dissecting, and research, also the Barnard appliance for testing rigidity by an interferometer method. The final chapter deals with polarised light and its various applications to the microscope.

The book is one to be recommended to the non-mathematical reader who desires to understand the optical theory of the microscope. Where Mr. Beck expresses views somewhat different from those current, he at least supports them with reasoned explanations and experiments.

Elements of Electrical Design. By Prof. Alfred Still. Pp. xxi+535. (London: McGraw-Hill Publishing Co., Ltd., 1924.) 25*s.* net.

Many problems connected with the design of electrical machines and apparatus are discussed in this volume. It is shown that in many cases sufficiently accurate solutions can be found by applying elementary mathematics and known physical laws. When designing high-voltage insulators, the reader is shown how to picture for himself the tubes of electrostatic induction in the insulator and the surrounding space, and when studying the action of electric generators and motors he pictures the conductors as cutting the magnetic flux. A concrete mental conception can thus be obtained of the actions which produce easily measurable results. The author points out that the difference between a laboratory course and a course in machine design is that the former is mainly concerned with analysis, separating out the losses in a machine, whilst the latter is concerned with synthesis, the building up of a machine. A course in design is a link between academic studies and practical engineering. It helps to develop engineering judgment, the student learning the relative importance of the many factors which enter into a commercial problem.

A First Chemistry for Schools. By W. H. Hewitt and S. T. E. Dark. Pp. viii+316. (London: Methuen and Co., Ltd., 1924.) 5*s.*

This book consists mainly of directions for the carrying out of a large number of experiments by a class of boys. The results when discussed in class should provide excellent material on which to build a sound structure, though more discussion in the text would be welcome. Our curiosity, which is aroused on p. 28 by a reference to the "chemist's definition" of acids in Chapter ix., is unfortunately not satisfied, and the laws of chemical combination are dealt with somewhat casually in a chapter headed "Reduction, Oxidation." The book contains some good features, for example, hints on keeping a note-book, though the practice of copying original readings into a best note-book is to be deplored. Molecules are discussed before atoms. This unusual method of approaching what is probably the most difficult part of the subject for beginners is sound, but the necessity for using two distinct units is not clearly brought out, and some confusion may arise as to the difference between the "ultimate" particles called molecules and the "indivisible" particles called atoms.

I principî della meccanica alla luce della critica. By Giuseppe Casazza. Pp. 174. (Roma, Milano and Napoli: Albrighi, Segati and C., 1921.) n.p.

"A new assault upon the rock of crystallised ideas of the nature of force" is what the author claims for this book. One or two headings will suffice to show how weak are his conceptions and poor his standards of scientific value: "Carnot's Cycle (or the prettiest cycle of nonsense or contrasense that can be imagined)," "Astronomical Mechanics (or the greatest scientific joke that has ever appeared under the heavens)," "The Principle of Relativity (or a comedy full of laughter)." S. B.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Earth Tides, Ocean Tides, and Local Geology.

IT was a source of satisfaction to me to read Dr. J. W. Evans's letter in NATURE of July 12, p. 49, and to note that he recognises the importance of a further study of earth tides. I quite agree with him in thinking that more earth-tide work is likely to be done if seismographic apparatus is adapted to that purpose than if observations are made only with an apparatus of the Michelson-Gale type, or with other apparatus equally refined and specialised. The results that can be obtained with seismographic instruments seem to me well worth having, even if the curves do not show the beautiful smoothness of those of the Michelson-Gale apparatus.

I am obliged, however, to differ with Dr. Evans, for reasons presently to be stated, in regard to the importance which he assigns to the local geology as a cause of anomalous results. Although our knowledge of the tides at sea and our command of mathematical methods are not sufficient for a rigorous computation of the effects of ocean tides on earth tides of like period, nevertheless they are sufficient not only to estimate the order of magnitude of these effects, but also to determine roughly their amount. It thus appears that the effects of the ocean tides are large enough to explain the observed anomalies in the earth tides, and that, in the cases treated by the Japanese investigators cited in my communication to NATURE of June 21 (vol. 113, p. 889), they do explain the anomalies quite as well as the inaccuracies of the method would allow one to expect. Furthermore, the influence of the local geology, although it must exist, is easily seen to be small. The French phrase for earth tides, *marées de l'écorce terrestre*, might seem to imply that earth tides are essentially a crustal phenomenon. Of course, we can observe only in or near the surface of the crust, but the tidal forces extend down to the centre of the earth, and, unless the matter of which the earth is composed is absolutely rigid, the tidal yielding must extend down to the centre also.

We may conceive the earth as divided into concentric spheroidal shells, and we may further suppose that the outermost shell is so thick that within it local geological differences die out, and that every shell within is homogeneous. The tide-producing force is a body force, acting on each particle of matter. Each shell receives the tidal distortion due to all the shells within it, and adds a small contribution of its own.[1] The tidal distortion of the outermost shell is mainly what it receives from the shells within, for we assume that the hypothetical shells never lose contact with one another. They are formed by mere hypothetical boundaries which we insert for our own convenience into a continuous body. The yielding of different parts of the outermost shell to tidal forces must be somewhat different, corresponding to local geologic and geographic conditions, but this difference must be decidedly small in comparison with the whole distortion accumulated from the centre outward.

In the preceding paragraphs the earth tides proper alone have been considered, not the secondary effects of ocean tides of like period. In respect to latter, the local geologic conditions might be of m importance than in respect to the primary earth tid for the ocean tides exert a surface pressure, no body force acting from centre to surface like th which causes the primary earth tides. Even he however, the effect of local conditions is proba not important, for the secondary effect of the ocea tides becomes large only when the oceanic tide, th is, the surface pressure, is in approximately the sa phase over large tracts of ocean. But when pressure is applied over a large area it goes de that is, a considerable depth must be attained bef the effects of surface pressure become small in co parison with the values at the surface. In th going deep the pressure involves portions of str that presumably are nearly alike all over the ea and depend but little for their properties on t geology and geography of the portions of the out most stratum directly above them. The earth tid show the effect of the yielding of the earth as a whc and to this the outer crust will generally contrib but a small part.

The Resonance Theory of Hearing.

IT is surprising that the resonance theory hearing continues to be revived in one form another. As soon as the ear is considered in relati to the other sense organs, it becomes apparent th all forms of resonance theory are profoundly u satisfactory and unphysiological.

In the course of evolution the hearing apparat derives from the tactile sense. In primitive fishes have the organs of the lateral line. One of the placed at the cephalic end, becomes invaginated form the otic vesicle, which develops into the co plicated membranous labyrinth. At first, the sens tions are purely tactile, being shocks transmitt through the watery medium. When the surroundi medium becomes air, and the vibrations assume periodic character, these are registered in the cochl —a derivation of the otic vesicle—and perceived sound. Why is the ear alone of all sense orga credited with the capacity for analysing the particul stimulus to which it is adapted to react? We do n claim this faculty for other organs. The reti perceives white light and does not analyse this in its component spectrum. If there are any analysi structures in the fundus of the eye, these are a mittedly scattered all over the retina. The skin, is true, possesses separate end organs for the sens tions of pressure, pain, cold, and heat. But who h ever imagined one end organ which will register s 40° C., and that particular temperature only, whi another registers 45°? Yet it is an apposition of series of such separately functioning end organs the cochlea that the supporters of the resonan theory ask us to accept.

The analogy which compares the fibres of th basilar membrane to piano strings continues appear in all the text-books of physiology. continuous, very small, spread-out membrane, varyir in width from the base upwards in the proportio of approximately 1 and 10, is supposed to contain series of end organs which must number at least 200 Each is delicately attuned to vibrate in sympath with one periodic vibration only. This marvello collection of resonators must be fully developed birth. It must remain unchanged throughout lif from the moment a baby picks up sounds unt

[1] The outer shells, of course, react on the inner shells, which therefore behave differently from what they would if the outer shells were absent.

leth at a ripe old age, while every other structure n he body is subject to the laws of growth and leeneration. Helmholtz himself at first thought ht the external pillars of the organ of Corti were h resonators. When it was shown that these do d exist in birds, which have particularly acute nering, he abandoned the external pillars in favour of he fibres of the basilar membrane. Nearly every ter structure of the cochlea (*e.g.* the tectorial mbrane, the hairlets) has at one time or another en credited with the functions of resonator. As Bonnier, in his work "L'Audition," so forcibly expresses t "pendant plus de deux siècles on tortura pour st [the resonance theory] l'anatomie, la physique, l'périmentation et la clinique."

No theory of hearing will be satisfactory unless it sarts with the assumption that the cochlea *as a wole* responds to sound vibrations. Each sound pture will create a pattern and make a composite ıpression in the cochlea, just as each visual im-pssion leaves a composite impression or picture on th retina. Examples of very interesting theories, blt up on these lines, are those of Wrightson and Fith, and that evolved by Bonnier. The ear is no nre an analysing apparatus than the blackened dm which registers the vibrations of a tuning-fork.

Leicester, September 27.

Organ-Pipes of Unusual Shapes.

The work of Principal J. A. Aldis (Nature, Aug. 30, p 309) on the Bicylindron is not only of practical importance to the scientific pipe-builder, but also constitutes an important addition to the acoustical theory of the organ-pipe. The Bicylindron as invented by Mr. Aldis is new to organ-practice, but there has existed for several hundred years a form of pipe, the theory of which is similar to that of the Bicylindron, although differing greatly in its solution. I refer to the Rohrflöte or Flûte à Cheminée (a particular case of which is found also in the Flauto d'Amore), the invention of which may probably be claimed by the German organ-builders of the seventeenth century. It was found that a stopped pipe of medium scale could be given a very beautiful smoothness of tone if the stopper were perforated by a narrow cylindrical hole, coaxial with the pipe. In old German organs the four-foot stopped diapason in wood was sometimes treated in this way, thereby replacing the rather nasal stopped diapason quality by one more desirable in a small organ. Later, the perforation was extended to metal pipes, a particular form known as the Rohrflöte being constructed, which owed its peculiar ringing quality to the extension of the main body of the pipe in a short narrow "chimney," and to the provision of a semicircular mouth with large ears, which enable the pipe to be tuned exactly.

The theory of the Rohrflöte was mathematically established by Dr. Robert Gerhardt in 1884.[1] Since this treatise is inaccessible to me, and I can find no adequate summary of his work, I have attempted the investigation with the following results, which I hope may one possessing Dr. Gerhardt's work will correct if his results and mine are at variance. The Rohrflöte is obviously a Bicylindron of which both pipes are open, and the one of larger diameter contains the mouth. The solution is, therefore, markedly different from that of Mr. Aldis. But in both cases the displacement is discontinuous at the plane joining the two tubes, although the differential coefficient of the displacement, with respect to measurement along the axis of the pipe, is continuous at that plane. Using the same treatment as that used for the Bicylindron, the solution for the Rohrflöte is

$$\frac{\tan mh}{\tan mk} = -\frac{r^2}{R^2},$$

where $m = 2\pi/\lambda$, λ being the wave-length of the resultant fundamental vibration, and h and k the speaking lengths, and r and R the radii of cross-section of the chimney and body respectively. If $r/R = \tan \pi/n$, a series of upper partials will be obtained, given by

$$1,\ n-1,\ n+1,\ 2n-1,\ 2n+1,\ \ldots \text{ etc.}$$

Even if "n" is not an integer, and the upper partials consequently inharmonic, their difference tones will give the octave of the fundamental, and hence the effect may not be altogether displeasing.

The solution of the equation has certain points of interest. If $k = qh$, the fundamental frequency will be $2q/n$ times that given by the body of the pipe, without a chimney, when closed. For particular examples one can use the expanded form of the relation:

$$-\frac{R^2}{r^2} = \frac{q - qC_3 \tan^2 mh + qC_5 \tan^4 mh - \ldots}{1 - qC_2 \tan^2 mh + qC_4 \tan^4 mh - \ldots}.$$

The equation may also be written:

$$\left(1 + \frac{r^2}{R^2}\right) \sin (1+q)mh = \left(1 - \frac{r^2}{R^2}\right) \sin (q-1)mh,$$

which, by taking the cases $q = 1$ and $r^2/R^2 = 1$, demonstrates the correctness of the expression. If for convenience we put $r^2/R^2 = w$, we are only concerned here with values of w between 0 and 1, although the equation would also serve for $w > 1$. Taking these limits into consideration, it is easily seen that $\left[\frac{\partial m}{\partial h}\right]_{w,k}$ is negative while $\left[\frac{\partial m}{\partial w}\right]_{h,k}$ is positive. This is in agreement with Dr. Audsley's statement that "if the diameter of the chimney be retained, the lengthening of it flattens the pitch of the pipe; while, on the other hand, if the length is retained and the diameter of the chimney is increased, the pitch is sharpened."[2]

It can also be shown that for any value of q, n may only vary between two definite limits if w varies from 0 to 1. When $q = 2$, n must lie between 3 and 4. When $q = 3$, n may vary from 4 to 6; and when $q = 4$, n may have values from 5 to 8·03. The region of possible values of n, therefore, increases in magnitude as q increases, and the mean value of n rises as q increases. The most desirable values of n are 5 and 7 for the Rohrflöte, and these can be obtained if the length of the chimney is between a third and a quarter of the length of the body of the pipe. This is not entirely in agreement with practice. Dom Bedos gives the design of a pipe in which the chimney is exactly one-third the diameter and one-half the length of the body. From the above theory this would give $n = 3{\cdot}75$, with a series of partials not very pleasing to the ear. But Dr. Audsley recommends a shorter chimney, as he considers the quality of the stop seriously impaired by the use of chimneys more than half the length of the body. "Let the chimneys be one-fourth the diameters of the respective bodies and from one-third to one-half the speaking lengths of the bodies, according to the quality of tone desired." This is very well supported by the theory. But from

[1] "Nova Acta der Kgl. Leop.-Carol-Deutschen Akademie der Naturforscher." Band XLVII., No. 1. Halle, 1884.

[2] "The Organ of the Twentieth Century." (London, 1919. Sampson Low, Marston and Co.)

the simple theory the best pipe of all would be one having the chimney one-fourth the length of the body and 0·337 of its diameter. The resulting series would be

1, 6, 8, 13, 15, 20, 22 . . .,

that is, $n=7$, with a fundamental frequency of 1½, that given by the body of the pipe, without a chimney, when closed. The tone of such a pipe would be very smooth, with a gentle ringing quality, and none of the open diapason richness given by the octave, twelfth, and double octave, and also none of the dull nasal quality exhibited by the closed diapason when the odd harmonics are present in excess.

The theory, moreover, offers an explanation of a phenomenon which puzzled organ-builders greatly on its discovery. It was found that if the chimney was turned inwards, and faced downwards instead of projecting outside the body of the pipe, neither pitch nor quality was altered. An examination of the formula shows that this would be so, the stationary vibration in the chimney being then composite.

We must also realise that the simple theory must be modified by the introduction of the end-corrections required at the mouth of the pipe and at the upper open end of the chimney. The correction at the mouth is large and amounts to nearly twice the depth if the pipe is of rectangular section (Brillouin), or three and a third times its radius if cylindrical (Cavaillé-Coll). In the case of the Rohrflöte, the correction is increased by the presence of the ears. The correction required at the upper end of the chimney is of unknown magnitude, although it would probably be proportional to the radius of cross-section of the chimney. The difficulty lies in the experimental fact that very little sound indeed is propagated from the open end of an open labial pipe, if the mouth is of the simple bay-leaf type and not inverted. Hence the open-end correction, which is required by the transmission of stationary vibration to spherical propagation, may be imaginary in this case. If, however, the mouthpiece of the pipe were removed and resonance determined by tuning-forks, both open ends would require a correction as given by Lord Rayleigh's formula.

Enough has perhaps been said to indicate the interest of the problem and how well worthy it would be of careful experimental investigation.

University of Birmingham.

A Sidelight on Bird Migration.

IT is usually accepted as an axiom of ornithology that the annual migration of birds consists of a movement from winter-quarters to breeding-quarters and back. The following notes, taken from observations made by me during the last five years on the North-west Frontier of India, may suggest that this view of migration does not entirely cover every case.

The crested lark (*Galerita cristata*) and the common pied bush-chat (*Pratincola caprata*) appear to come to the Peshawar valley to breed, and, at any rate in some cases, to leave the valley as soon as their young are able to fly, and spend the hottest months in the nearest hills. Between the end of August and the middle of September both species return to the valley. The movements of the two species are not identical, and must therefore be described separately.

Crested larks may be seen in the Peshawar valley at all seasons. During the winter months they congregate in small flocks. About the beginning of March the number of flocks begin to increase. By the end of the month most of them have paired, and during the first few days of April the number of la seems to decrease. During April the eggs of t species may be found in every field and on every pi of waste ground. The earliest date on which I h found a nest containing eggs in this district is Apri and the latest April 29. By the end of May, cres larks have become scarcer in the valley than they at any other season. This scarcity continues u about the end of August, when the numbers ag greatly increase. About the middle of October slight decrease again takes place, after which th appear to remain constant until the cycle of mo ment recommences in March.

No common pied bush-chats appear to remain the Peshawar valley for the winter. The earliest d on which I have noted the appearance of this spec is Feb. 28. The majority of this species seem to l in April. The earliest date on which I have fou a nest of this species containing eggs is April 7, a the latest (except for two nests containing hatchi eggs found on July 11, 1922) is May 17. By far t majority of eggs are laid during the second and th weeks of April. By the end of May, bush-chats, li the larks, become scarce in the valley, about t middle of September their numbers again increa and soon after they leave for the winter. The lat date on which I have observed them is Oct. 1.

During the summer months, when crested lar and pied bush-chats become scarce in the Peshaw valley itself, their numbers undergo a considera increase on the hillsides below Cherat, at elevatio varying from two thousand to three thousand f above the general level of the valley. The lar proportion of young birds to be seen on these hillsid at this time is very striking, and one is almost irresi ibly led to the conclusion that these two species, li the human inhabitants of Peshawar, have taken th families to the hills.

From the foregoing observations the following t deductions are, perhaps, permissible:

First: that the common pied bush-chat, comi from somewhere "down country," breeds in t Peshawar valley, spends, in a great number of cas the hottest months in the hills, and returns to wint quarters through the Peshawar valley.

Secondly: that some of those crested larks th breed in the Peshawar valley also go to the hills f three or four months after breeding.

If this is a true reading of the facts, is it not possib that other species of birds also may migrate betwe three localities instead of the more usual two? T matter would bear the attention of all observers birds.

Rockets and High Altitude Research.

A RECENT book review in NATURE for August 2 1924, page 270, of Herr Oberth's "Die Rakete den Planetenräumen," 1923, calls for a brief commen

Following the tone of the book, Oberth is credit with being more ambitious than the writer of th comment, in suggesting the construction of a rock large enough to carry passengers, even to the distanc of the planets, whereas my main object is present as the sending of a rocket to the moon, propelled b successive charges of nitrocellulose.

I first became seriously interested in the gener problem of high altitude research in 1899, and 1907 I submitted, *for publication*, an article discussi the use of heat for expelling material at a hi velocity, in order to furnish a propulsive force sufficie to permit navigation of interplanetary space.

The idea of using hydrogen and oxygen in multip

rckets was conceived in 1909; the general theory w put in satisfactory form in 1912; and the use o these substances mentioned in Smithsonian Miscellaneous Collections, Vol. 71, No. 2, for 1919. Oberth, on the other hand, claims in his book to have rde his first finished plan of a rocket to use wet gu-cotton in 1909, and to have drawn up his first pn of an hydrogen-oxygen rocket in 1912.

Further, as to the use of liquid propellants and ctinuous combustion, these were suggested by m, *by publication*, in 1914, and were *tested experimtally* in 1921, the development carried on under r direction since that time having been confined eirely to rockets of this type.

t may be mentioned here that a request was reived from Herr Oberth, dated May 3, 1922, sting that he had been working for some years o the problem of passing over the atmosphere of th earth, and requesting me to send any books I ght have on the subject. Compliance was made b sending a copy of the above Smithsonian publicatn; and a copy of Herr Oberth's monograph, wich incidentally deals with theory rather than with eperiments performed, was received on July 19, 1923.

As to the idea of a passenger-carrying rocket, al the reaching of planetary distances, it is only fir to say that, while I have considered these matters wh much care, and have gone so far as to make laoratory tests to check my conclusions, I am now, al always have been, only too well aware of the cnservatism of the average person regarding new aplications of physics. Thus, because it has been m desire to make actual progress and to conduct a:ual experiments, I have endeavoured, so far as pssible, to focus attention on the problems that l immediately ahead, the first of which is an explorath of the earth's atmosphere, and have restricted te discussion of certain sensational, but nevertheless ieresting and realisable, matters to confidential rports.

Ive- (and Six)-Point Support: "Right as a Trivet."

As practical problems are usually a function of several variables, individual opinions are determined l the order of importance attached to the variables. he more numerous the conditions, the truer becomes le old expression, "Quot homines tot sententiae."

If in this question of fits we place pure mathematical d geometrical principles first, we have one point of iew. As there are others which I think largely ctermine the workshop attitude and possibly the 'Enfield Tradition," I should like to refer to some of em very briefly; to do so fully is not possible in a :ter.

Let us consider the example from Thomson and ait quoted by Sir George Greenhill in his letter i Nature of September 27. It is stated therein at "the rifle may be replaced any number of mes in precisely the same position." If much curacy is demanded, that statement is not correct, cause the materials at the points of support, where e forces of impact may be considerable, swage or ear away and quickly so when the parts are handled they must be in the workshop.

In designing our apparatus we must consider the ysical properties of the materials as well as the ometrical principles involved. The materials dermine the areas over which the loads must be stributed and, if they cannot be approximately oints, what value are we to attach to the principles f geometrical fits?

To demonstrate the practical application of these principles Thomson and Tait selected a bad example; as in the case of a rifle the convex abutments cannot be placed in their more proper geometrical position within the bore. Suppose a cylinder mounted in the manner described has longitudinal freedom and is constrained transversely: the slightest bend of the cylinder under its own weight, or by the action of the sun on one side of it, may destroy the longitudinal freedom, as the circular section of the fixed abutments must then accommodate an elliptic section of the piece.

The geometrical principle is based on the assumption that *all* the parts involved are absolutely rigid. We practical men, whose business it is to understand the limitations of materials, dare make no such assumption. In the workshop most of us are thoroughly familiar with geometrical principles. We were taught them in the universities and colleges. If we do not slavishly adopt them, it is generally with good reasons.

There has been within the past few years a good deal of adverse criticism of the practical trial-and-error type of man in industry, the articles having usually for their text "The Neglect of Science by Industry." If the writers of these articles were better informed, I feel sure they would find the converse text "The Neglect of Industry by Science" a more appropriate one.

Fine Structures in Non-Hydrogenic Atoms.[1]

For some months we have been studying the data on fine structures of the lines of non-hydrogenic atoms. These fine structures arise, in every case so far studied, from transitions between the components of complex spectral levels. Save for a few isolated examples, it can be readily proved that fine structures are not due to isotopy. (See Scientific Paper No. 490 of the Bureau of Standards.)

It is necessary in certain cases to introduce a *fine quantum number f*, the values of which characterise the different components of a complex level. In some elements, a selection principle for this quantum number makes its presence felt, and the separations of the components are in integral ratios. So far, attempts to establish intensity rules have failed, but this part of the work is not finished.

Nagaoka, Sugiura, and Mishima (*Jap. Jour. of Physics*, 2, 121, 1923) have published measurements of mercury fine structures which are precise to almost 10^{-4} A. These data have enabled us to analyse successfully the complicated fine structures of nearly all the mercury lines they studied.

The phenomena of fine structures are so diverse that we cannot hope to have a unified physical explanation for them. In isolated cases, such as the 4_4 terms of Al^+ studied by Paschen, they may be due to relativity. In other cases, the components of a complex level behave like a tiny multiplet, and the structure may depend on magnetism for its origin. In other cases, magnetic fields do not affect the fine structures, and we must look to unknown dynamical peculiarities of the individual element for an explanation.

A paper covering the whole field will soon be published.

The Shrinkage of Gelatine.

IN the *Kolloid-Zeitschrift* for August my friend Mr. Emil Hatschek describes some beautiful and symmetrical figures which result from the slow drying and consequent shrinkage of variously shaped blocks of gelatine. A squat cylinder shrinks into a biconcave disc with deeply grooved periphery; a cube becomes a beautiful stellate figure, with apices corresponding to the eight corners of the cube, and with sides which sag in towards a more or less cubical central hollow. The former case shows a striking resemblance to a simple vertebra, such as that of a cartilaginous fish; and it is very curious to see how so simple a phenomenon as shrinkage converts a cylindrical block into the form of an "amphicœlous" vertebra.

For the moment, however, I am less concerned with biological analogies than with what I believe to be a simple general explanation of these "shrinkage-figures." In one of Plateau's experiments, we take two parallel hoops of wire (within certain limits of distance apart), blow a soap-bubble between them, and then gradually exhaust the bubble; we thereby obtain a figure bounded above and below by concave spherical surfaces, and surrounded by a peripheral groove which is a portion of a catenoid. Again, if we dip a skeleton-cube of wire into soap-solution, films run inwards from the twelve sides in such a way that the common edge of three films meets either each corner of a plane quadrilateral fenestra, or each corner of a little central cube; the latter is the more symmetrical figure of the two, but in each case a figure *minimæ areæ* is realised, automatically and instantaneously.

The two gelatine shrinkage-figures which I have mentioned are nothing more nor less than *approximations* to these minimal configurations. The corners and edges of the gelatine block are the first parts to show shrinkage, for here the surface for evaporation has the highest ratio to the content within; thus edges and corners become rigid in comparison with the rest, and form (as it were) a framework for the whole mass. Bounded by this skeletal framework the mass of gelatine shrinks away; and its surfaces tend to realise, slowly and imperfectly, the self-same minimal-surface configurations which the soap-film achieves in immediate perfection. The actual curved surfaces of the shrinking cube are very beautiful: I take them to be conformal transformations between the original plane side of the cube and the square truncated pyramid which the four films on each side bound, as they pass from the outer skeleton to the little central cube; but the full elucidation of these surfaces is a job for the mathematician.

Only in small particulars, easy of explanation, do the actual shrinkage-figures differ from the above description. The shrinking edges and corners are not lines or points but graded areas, and the subsequent form of the curved surfaces is somewhat complicated thereby. Again, while the edges tend to become rigid, they do so imperfectly; they act not precisely as do the wire edges of our skeleton-cube, but rather as these would do were they replaced by threads. That is to say, the edges themselves tend to sag inwards, and do so, doubtless, in circular arcs. A minor point, to which Mr. Hatschek has directed attention, is that at first the sides of the several figures bulge slightly outwards—they show a temporary convexity before they become concave. This is simply due to the fact that the edges of the figure contract perceptibly before the whole volume is materially reduced.

Microseisms associated with the Incidence of t South-west Monsoon.

THE late Dr. Klotz was the first to suggest relationship between disturbed weather in the No Atlantic and the largest microseismic moveme at Ottawa. The microseisms recorded by the Mil Shaw seismograph at the Colaba Observatory dur the burst of the monsoon on the west coast of Indian Peninsula present many interesting featu and indicate the possibilities of a forecast be made of the approaching monsoon at least a we ahead. The seismograph, which is installed in underground constant temperature room, gi records remarkably free from microseisms dur the cold weather period.

Microseismic movements of a type which is qu characteristic of the south-west monsoon peri make their first appearance in the seismograms t the end of May with the advance of the monso in the south-east Arabian Sea, becoming more a more pronounced as the monsoon currents approa Bombay. They become less marked or disapp during a temporary break in the monsoon a reappear with the strengthening of the curren This year the first indication of disturbed weath in the south-east Arabian Sea was obtained on M 21, and microseisms of the monsoon type made th first appearance in the Colaba records on the n day; these became more marked on June 2, wh the monsoon finally appeared on the Malabar co with rough seas and heavy rain. Very well-mark microseismic movements were noticed in the rec for June 12, on which day Bombay received its fi monsoon rainfall.

Potential Gradient and Atmospheric Pollution

RECENT correspondence (NATURE, April 5 a June 14) on the connexion between the potent gradient and the degree of pollution of the atmosph prompts me to put forward a suggestion to expla the alleged influence of a high-tension electric field plant growth.

It is well known to all workers with high tensi that, owing to the fact that the corona dischar takes place more readily from negatively than fr positively charged wires, the dust-particles of t surrounding air become negatively charged and a rapidly precipitated upon neutral or positive charged surfaces, the air being thus freed fr pollution. Conjoin with this fact the unquestiona deleterious influence of an excessive dust content the air upon vegetation, as illustrated, for example, the difficulties of the urban horticulturist as co pared with his rural competitor, or in the dama wreaked by a cement-works upon all vegetati in its lee, and we have at least a possible *vera cau* for the beneficial action of the high-tension ne work.

The conflicting evidence obtained by differe observers, and particularly the difference, noted l some, in the effect in dry and wet seasons, wou also find a ready explanation in the obvious fact th the greatest benefit would accrue under conditions maximum atmospheric pollution.

Optical Records and Relativity.

By Prof. C. Lloyd Morgan, F.R.S.

Probably the majority of physicists acknowledge the existence of events (and the clusters of events we call things), out there in the external world, whether we have sensory acquaintance with them or not. They believe that an object of vision is seen only when light-waves, transmitted from some cluster of physical events as their proximate source, reach the retina of the eye, and that on receipt of advenient influence which stirs sundry retinal events, there somehow arises conscious reference to an object of vision. It is not within their province to consider how this conscious reference may best be interpreted. That falls within the province of the psychologist. Just as it is for the physicist to tell the story of the manner in which light-waves take origin in some proximate source, how they reach the retina, and what is the set of physical events in the retinal record, so it is for the psychologist to tell the story of the manner in which conscious reference to the object of vision has come about.

The physicist, then, tells *his* story and leaves the psychologist to tell his story. Broadly speaking, the former is that of radiant influence from its proximate source to its proximate outcome; the latter that of perceptual reference to the object of vision.

I take it that from the physical point of view we may distinguish two sets of events. There is a set of events beyond the confines of our body, and there is a set of events within the confines of our body. In the set of external events there are specialised groups of events from which radiant influence is transmitted in ways which it is for the physicist to describe and interpret. When such radiant influence is advenient on one of the more highly developed organisms, such as we are, it forms an optical "image" on the retina of the eye. A set of events in the pattern of the image is called into being in the spread-out and curved surface of the retina. This "receptor-pattern" may be regarded as a record (within the confines of the organism) of some group of events beyond the confines of the organism. It is no less physical, as a set of interrelated events which occur in the optical record of the retina, than the set of events in the external world which is the proximate source of that record.

Beyond the record, in our present context, the physicist is not concerned to trace the further course of events within the organism. However important this may be for the elucidation of perceptual process, he leaves that to the physiologist. Hence he restricts his inquiry to the task of co-relating (*a*) the events at the proximate source of the record in the external world, with (*b*) the events in the optical record itself; but he cannot get along with this (his proper) task without conscious reference to (*a*) and to (*b*). Since this does not fall within his province, he must accept some working hypothesis as to its nature from those within whose province it does fall for consideration. There are, however, two in the field. It may be (*α*) that the spatio-temporal relations in the retinal record *reveal* those that obtain in the source of that record; that is, that in and through the record the mind directly apprehends the spatio-temporal course of events in its source; or it may be (*β*) that the nature of conscious reference in perception is such that the object of vision is fashioned on the spatio-temporal configuration *of the record*; that is, that changes in the record are referred to that which is the external source of that record.

With the aid of photography, other optical records than those in the retina may be obtained. But the photographic record, when it is seen, is an object of vision, and therefore implies a retinal record; so that we have here only an instance of vision at second-hand.

Now the first-hand optical record in the retina, or its substitute at second-hand in the photograph, has a quite definite shape, as a snapshot phase of changing spatio-temporal relations therein; and whatever may be that shape in the record, that too is the shape of the object of vision. That which gives an elliptical record is seen, under naïve perception, as elliptical. In matters terrestrial, and in matters that can be brought within the range of manipulation under touch-contact (and its ancillary measuring-rods, callipers, and so forth), there is opportunity for co-relating the spatio-temporal relations in the optical record, and in the source of that record as dealt with by manipulation. There is need for such co-relation; for the shape of a thing, say a coin, as given under reference from touch-manipulation, is often different from the shape of that thing as given in the optical record, and as referred to the object of vision.

Let us admit that the coin as a physical thing is, for our knowledge, a "construct" which we deliberately frame for scientific purposes by combining the net result of all visual and (in the case of this and other terrestrial things) all tactual records obtained in the course of manipulation. It is on this basis that the physicist acknowledges a physical thing existent in its own right; and where vision is concerned, that thing is the source of advenient influence that reaches the retina and gives an optical record. The inquirer in what may be called the field of "classical optics" (briefly characterised as "the science of light regarded as the medium of sight") is one whose special business it is to co-relate the story of physical influence with that of perceptual reference with its location of the object of vision. He has reached certain generalisations with regard to the occurrences he observes in this twofold aspect. Perhaps the most salient is this: No matter how devious the course of a light ray in accordance with the non-homogeneous medium of physical events through which it is transmitted (under refraction, reflection, and so forth), conscious reference to the object of vision is along the line of the final path of that ray by which it reaches the recording retina. This is projective reference or, as Sir Charles Sherrington calls it, "projicience" ("Integrative Action of the Nervous System," p. 324). He distinctly states that it is a *psychical* process. He traces its connexion with the evolution of "distance receptors." Initially naïvely perceptual with meaning (including visual distance) for the practical behaviour of animal life, it leads up, under further mental elaboration, to conscious reference to the object of vision. The gradually

acquired location of the object of vision is commonly interpreted in terms of this elaboration. Under optical inquiry an orderly co-relation of the "place of location" of the object of vision with the "assigned place" of the proximate source of the light rays from a physical object, is set forth in the text-books of classical optics. This is the interpretation of perceptual reference that I labelled (β) in a previous paragraph.

Under (α)—the doctrine of direct apprehension—the interpretation is quite different. It is advocated by new realists of the type of Prof. Alexander, by critical realists of the older type (represented by Prof. Dawes Hicks), and of the newer type (represented by Prof. Santayana). It underlies Prof. Whitehead's "Concept of Nature" and Mr. Bertrand Russell's "Analysis of Mind." It is certainly widely accepted on grounds not always clearly set forth; and it has authoritative expression.

What is its interpretation of conscious reference? Subject to correction, I think it comes to this in its selective form as advocated by Prof. Alexander. The entity which we call a mind is "compresent" with a vast number of certain other entities named, let us say, "sensa." Just as, in physical regard, physical influence flows in to some given physical entity from some other physical entity or entities, so too, in psychical regard, psychical influence flows in to the mind from some sensum or sensa with which it is compresent, or, at any rate, the mind is affected by them; and on receipt of such influence (or such affection) there is what we call reference on the part of that mind to the sensum or sensa. Reference, therefore, is the psychical reaction of the mind in its relation to sensa, and it discloses or reveals the intrinsic nature of the sensum with which the mind is compresent. Revelation of this order is illustrated by the direct apprehension of a certain kind of sensa in vision.

Such in its essential features is, if I mistake not, the doctrine of reference which is alternative to that of projicience or projection. The sense-organs—in our context the retinal records—are only *instrumental* to direct apprehension, for example, of a distant sensum which has in itself the quality of redness. It may be true enough that, whenever colour vision is in evidence, there always occur in the receptor-pattern of the retina, or the choroid, certain complex chemical changes. But what of that? It merely shows (if such be the facts) that the bodily instrument used by the mind in direct apprehension is of such and such a nature. It may be that it takes the human infant some seven or eight weeks clearly to focus and locate an object of vision, and perhaps another seven or eight weeks (cf. Milicent Shinn, "Biography of a Baby") to co-relate the seeing and the manipulation of that which then becomes for its apprehension one and the same object. What of that? It merely shows, if the inference from the observed facts be valid, that the physiological means subservient to the psychical end of apprehension are subject to a process of progressive development. Physiologists and biologists discuss such subsidiary matters. Direct apprehension on the part of the mind is there from the first and all the time.

We have then an α-interpretation and a β-interpretation, both distinctively concerned with a mental or psychical process; and the point of emphasis is that there are *alternative* hypotheses as to the nat and outcome of conscious reference in naïve percepti The difference between them may be illustrated the alternative interpretations of "mirror image" When a man shaves all that happens, in manipulati touch under the razor, to his chin that he cannot s happens also to the mirror image that he does s Clearly there is need for co-relating these several even The interpretation of classical optics is familiar enou On the "sensum theory"—either in its "selectiv or in its "generative" form—the co-relation of t visual sensa, apprehended as mirror-images, with t tactual sensa apprehended under manipulation of t razor (together with sundry auditory and olfacto sensa) demands a much more intricate and elabora treatment such as is discussed in Mr. Broa "Scientific Thought." There are, then, two qui different interpretations. Of these one or other clai acceptance under the searching criticism which lea from an initial assumption to acknowledgment of validity as a basis for further procedure.

Furthermore, apart from the projicience or pr jection entertained as a policy in classical optics, a discussed from an evolutionary point of view by S Charles Sherrington—apart, let us say, from t biological and psychological arguments in favour reference *from* the record *to* the object of vision—it sufficiently well known that there is, in the wider fie of thought, a philosophical hypothesis based whol on projicience—that which Prof. Wildon Carr h presented in "The Theory of Monads"; and it is al pretty clear that other idealist systems, in so far objective, proceed on the basis of the hypothesis projicience rather than of that of direct apprehensio So here again—apart from "subjectivism," which v may regard as out of court—we have to realise th there are *two* alternative interpretations of conscio reference, no doubt in somewhat variant forms.

Revert now to the concept of the optical recor photographic or retinal. All that we experience visual perception when there is an object of visi implies an optical record, whatever else it may impl in focussing the eyes and in the very complex set factors concerned in the perception of visual distanc In the case of a coin, all that we visually know cor cerning it is based on a vast number of varying optic records with intrinsic spatial relations of position points distinguishable within it. On this basis w speak of the object of vision as round, elliptical, an so forth. Speaking of the coin: Such and such (w say) it is as object of vision. But what is *it*?

There are other records of "it"—those based o tactual contact-records, with behaviour in manipula tion. These, too, are records of "the coin." We co relate these contact-records with those optical records and we incorporate both in a pretty consistent schem where each has meaning in terms of the other. In th optical record we take into consideration (a) the poin of view from which the record is obtained, (b) th physical path of the light-waves that reach that recor from some physical source, and so on. Then, con currently, we co-relate the whole set of optical record with the whole set of contact-records given in respec of the things, such as the coin, which lie within th limited reach of manipulation. Combining all the data

ided by all the records, we construct "the coin" s has, step by step, taken form in our knowledge d on these records. But what is "it"? What is e coin"? Some may say it is just this construct. ers may say: This no doubt it is for the knowledge h gradually took form in our childhood. But this struct is founded on conscious reference—if you like great number of co-related acts of referring—to a sical thing, existent "on its own" independently ll such percipient processes.

ow whether this belief or acknowledgment of the pendent existence of a specific cluster of physical nts which is the source of no less physical records ustifiable at the bar of logic or not, I submit the man of practical common sense, *and* the man cience as physicist, *do* proceed, in all their work- y hours, on the basis of this acknowledgment, as a cy if not as a creed. I feel confident that most sicists, and the general public who are interested he outcome of their inquiries, do claim that recently uired knowledge with regard to relativity demands only a radical modification of policy in dealing with physical universe, which was a "going concern" before man came on to the scene of events, but a radical modification of the orthodox scientific d now spoken of, in the past tense, as that of assical mechanics."

physical outsider meddles with relativity at his l. He may, however, ask questions, even if he be competent to make assertions. Here let it be said t, unless he be smitten with the incurable disease enile folly, he must freely and fully accept all that sical science has securely established in its splendid ance since the days of his youth. That being so, may still venture to ask questions.

1) Are we not, in the crucial issues that arise under sical relativity, dealing only with optical records, tographic or retinal, and with an acknowledged sical source of those records?

2) Must we not regard the records as physical no than their source?

3) Are we not, from the nature of the phenomena evidence, precluded from obtaining any contact- ords, under touch-manipulation, of the spatio- oral events in the distant source, though we deal ely, on this wise, with the optical record, spectro- pic or other, on the photographic plate?

4) Are we not, therefore, in physical regard, co- ating, under some relevant transformation formula, rentzian or other, the physical events optically orded, with the distant source-events thus recorded?

5) Is not the outcome: Such and such is the co- ation of *these* events with *those*?

6) May we, on the basal principle of relativity, give macy in "reality" to either set of events thus co- ated, since each is acknowledged as physically eal" in the same sense?

7) In terms of so-called "warping," are we justified saying more than that these source-events *or* those ord-events are "warped"—*i.e.* stand in need of nsformation—each relatively to the other?

8) Is it not for convenience of policy only that varp" is assigned to one or the other?

9) If, as a matter of scientific creed, primacy in eality" be given to one or the other, and we be bidden to believe that these and not those are "warped," is this on strictly physical grounds?

(10) Or is it on grounds other than physical—*meta*-physical in the Aristotelian sense—namely, in accordance with a doctrine of perceptual reference, *i.e.* of the nature of a *mental* process (however simple or however complex) and its outcome?

(11) Is there one universally accepted doctrine of perceptual reference in vision, or are there two, (*α*) direct apprehension, and (*β*) projicience (or projection)?

(12) Since, as a matter of plain history, there have been, and still are, two different hypotheses, is it for the physicist as such to pronounce judgment one way or the other?

(13) If (*α*) be accepted by this or that physicist on the basis of one of the two "metaphysical" hypotheses, should not this be stated?

(14) If the physicist, as a wise cobbler, sticks to his last, and says that the nature and origin of perceptual reference is not his business, should he not leave the matter open? If it be no concern of his, *qua* physicist, should he not hand it over to those who make it their special province of inquiry?

(15) If some of those who have given careful and prolonged consideration to this problem in all its bearings (and its bearings are many) regard the balance of evidence as, in their judgment, in favour of visual projicience, does this imply rejection of physical relativity or of any valid inference therefrom?

(16) What does all this mean for the man in the street, or the smoking-room, who is interested in such matters?

Expressed in terms which may perhaps be "understanded of the people," it means something like this:

(i.) All the established results of physical science, as such, and all valid inferences therefrom, are fully and gladly accepted.

(ii.) There are two quite different hypotheses in respect of perceptual reference. On *this* hypothesis, just as the shape of a coin as seen from any given position is that of the "image" on the retina; just as the partially immersed rod looks bent because such is its record in the retinal receptor-pattern; just as the "mirror image" of a man's chin is located differently by its owner and the barber who shaves him; just as, in these terrestrial matters of common experience, what happens in the record is the basis of all that we see, and is projiciently referred to the set of physical events which give that record; so too are all spatio-temporal changes as optically recorded (subject to Lorentzian or other transformation) projiciently referred to their distant physical source—for such is the nature of vision.

(iii.) It follows that "local spaces" and "local times" are, broadly speaking, illusions of vision, none the less interesting, none the less matters for scientific inquiry, none the less germane to the policy of physical interpretation, but still having their seat in the optical record and not in the source of events thus recorded, though projiciently referred thereto.

(iv.) It follows, too, that if transformation of events be interpreted in terms of projicience and not in terms of direct apprehension, the source-events themselves are nowise transformed, and the scientific creed of classical mechanics stands in no need of revision.

Archæology from the Air.

By O. G. S. CRAWFORD.

LONG before aeroplanes were invented it was confidently hoped that vertical photographs would some day be taken; and it was felt certain that, if so, they would greatly assist archæology. Major Elsdale was the pioneer of air-photography in the British Army. Between about 1880 and 1887 he carried out many experiments from free balloons, and also invented a method of sending up small balloons, just large

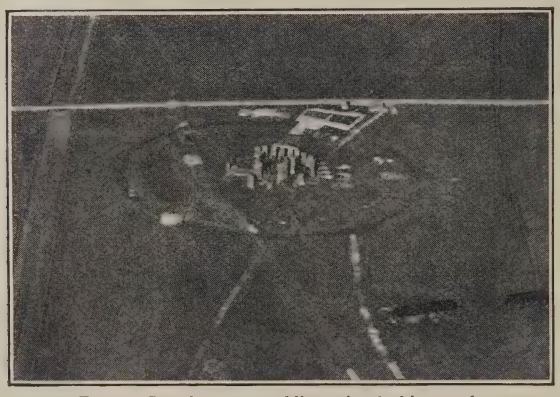

FIG. 1.—Stonehenge: an oblique view looking north.

enough to carry a camera, which exposed a certain number of plates automatically; then the balloon emptied itself of some of its gas and came down. Some of the results were quite good considering the difficulties. In 1891 Lieut. C. F. Close (now Col. Sir Charles Close) suggested to the Surveyor-General of India that the India Office should be asked to send out similar apparatus to photograph from the air the ancient ruined cities round Agra, with the view of constructing a map from the air-photos. The scheme was approved and the apparatus was sent to India; but official difficulties of the usual type supervened. The result was that Agra was cut out of the scheme; and a few photos were taken over Calcutta at an unfavourable season of the year, and the opportunity was lost. After Major Elsdale left the Balloon Establishment in 1888, little or nothing was done at home in this matter: and after 1892 the Survey of India took no more interest in balloon photography. Major Elsdale spent much of his own money on the experiments in question; but ballooning was not much in favour in the 'eighties, although some progress was made, and he received little or no official support in his balloon-photo experiments.

In 1906 Lieut. P. H. Sharpe took a vertical and an oblique photograph of Stonehenge from a war-balloon; these were published in *Archæologia* (vol. 60) by Col. Capper. During several years immediately preceding the War, Mr. Henry S. Wellcome successfully used large box-kites, with specially devised automatic control cameras for photographing his archæological sites and excavations in the Upper Nile regions of the Anglo-Egyptian Sudan.

During the War, when aeroplane photographs first became common, it might have been expected that archæological features would have been observed; but in the British sector in France none were seen, so far as I know. The photographs were often taken at a great height, over country which is archæologically barren or which was too rankly overgrown to show results. Moreover, the interpretation of air-photographs for military purposes was a new art and in itself sufficiently fascinating to oust academic interests for a time. Only on other fronts was time found for archæology in the air, and again it was an officer of the Royal Engineers who led the way. Col. Beazeley observed and photographed in Iraq in 1917, cities of which the ruins were unintelligible on the ground. On an air-photograph these ruins were seen as an orderly arrangement of streets and houses. This marked a very definite advance, for it proved that air-photography could add to knowledge, and that it would be an invaluable aid to excavation. To Col. Beazeley is due the credit for the first actual application of air-photography to archæology. In the first flush of excitement it has sometimes been forgotten that he was the pioneer in practice, and that he was the first man to take air-photographs from an aeroplane for purely archæological purpose. So far as I know, Col. Beazeley has not followed up his first results; but it is to be hoped that some one will, for Iraq is a most suitable country for "archæography."

The birth of the new study in England may be said to date from 1922 when Air Commodore Clark Hall observed certain curious marks on R.A.F. air-photos taken in Hampshire. With him must be mentioned Flight-Lieut. Haslam, who took a number of photo-

FIG. 2.—Stonehenge and environs.

graphs near Winchester showing what turned out to be Celtic fields. Air Commodore Clark Hall showed these photographs to Dr. Williams-Freeman, who told me to see them. Dr. Williams-Freeman and I had always been hoping for air-photographs of English soil; and looking at these we saw that our expectations were fulfilled, and even surpassed, by what was revealed. It was possible from these photographs to make a map of the Celtic field-system near Winchester; it was published in the *Geographical Journal* for May 1923, and reprinted in "Air Survey and Archæology

o. (Ordnance Survey Professional Paper No. 7).
.y archæological air-photographs have been taken
yhe School of Army Co-operation at Old Sarum.
ecently the Air Ministry has sanctioned the transfer
o the Ordnance Survey Office of all air-photographs
co aining archæological information, which are not

ning from just above the highest point of the wood shown in the bottom
t-hand corner of the illustration and curving towards the first line of
e-clumps, the third of which from the left stands partly on the avenue.
ie tumuli appeared as faint circular markings. The course of the
enue has been slightly emphasised in preparing the illustration.

rcuired for service purposes. Thus, the connexion
bween air-photography and the Royal Engineers,
bun about 1880 by Major Elsdale and continued by
C. Beazeley, has been maintained. Needless to point
o', air-photographs are of great use, when checked
a l supplemented by field work, in revising the
a hæological information on the Ordnance Maps.

Popular interest was first aroused by the discovery of
natives showing, for the first time, the complete course
o the Stonehenge Avenue (eastern branch) (Fig. 3).
Ie history of this has been told before, and I do not
ppose to repeat it here. Full details will be found
imy monograph on "Air Survey and Archæology."
Ie photographs of the avenue were taken in the dry
yar of 1921 by the Old Sarum squadron; but their
e hæological importance was not recognised until two
yars later, in 1923. At the present moment the
pblem before us is to find a suitable method of
rroducing air-photographs, so that the pictures may
come generally accessible to archæologists for pur-
poses of study.

It is usually imagined that the camera, when fixed
i an aeroplane, records marks on the ground which
re invisible to the eye of an observer. That is not
s. The observer can see these marks more plainly
tan the camera, for he sees them in colour. The most
rmarkable discoveries which have been made are
(e to plants, which are sensitive to slight differences
(soil and moisture. For example, if a ditch has been
g on a chalk down and the down has afterwards
len ploughed flat and sown with corn, for ever after-
wards the subsoil filling (or silt) of that ditch differs from the adjacent never-disturbed soil. Nothing can ever restore chalk once dug to its former state. Archæologists have long known this, for one of the principal needs in excavation is to distinguish between disturbed and undisturbed soil. But one cannot dig up a whole field or several fields to find a ditch which after all may not exist. Here it is that a vertical view helps; for the effect of this moister silt upon a crop of corn is to promote its growth and deepen its colour. Thus from above one sees, and can photograph, a belt of darker green corn following the line of the vanished ditch. These lines are sometimes visible on the ground, from across a valley or at even closer quarters. Sometimes (as in parts of the Stonehenge Avenue) they are quite invisible. But always, when more than a single ditch is concerned, the *distant* view is necessary to convert chaos into order. The reason for this necessity can best be explained by means of a comparison. If one looks through a magnifying-glass at a half-tone illustration made through a coarse screen, it ceases to be seen as a picture and becomes a meaningless maze of blurred dots. If one holds it some distance off and looks at it with the naked eye it becomes a picture again. The observer on the ground is like the user of the magnifying-glass; the observer (or camera) in the air is like him who looks at the half-tone picture from a distance.

Now the majority of our prehistoric sites, and many later ones, were seamed with ditches and pits, dug for drainage, storage, habitation, defence or boundary purposes. Many exist to-day on the downs, undisturbed and turf covered; many more have been flattened by cultivation. All of the latter can be re-

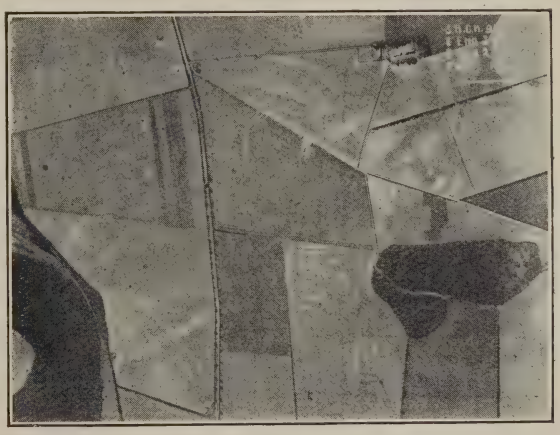

FIG. 4.—Celtic lynchets and ditches on Borough Down near Winchester.

discovered by air-photography, provided only that the arable has not been allowed to revert to grass. Even then traces of the ditches are sometimes visible, especially on poor soils and in dry summers, by a belt of darker green. Air observation, however, is most fruitful when young crops are growing; then discovery is easy and rapid, and every flight is productive. Such sites may afterwards be seen to exist by an observer on the ground; but few of them could ever have been *discovered* except from the air. Chalk is not the only soil that produces these streak-sites; they have been

observed on oolitic limestone near Bath and plateau gravel near Exbury.

A few words only are necessary to describe the other factors which enable air-photography to record ancient sites. Prehistoric cultivation-banks—what I have called lynchets of Celtic type—are revealed because they either throw slight shadows or because when ploughed they appear as belts of lighter soil, from the chalk

FIG. 5.—Battlesbury Camp, Wiltshire.

grains mixed with them. From photographs the Celtic field-system of a district can be accurately mapped. Again, rabbits work in the looser silt of filled-up ditches (as well as in the soil of the lynchets), and if there are many rabbits a white line, or row of white patches, is visible from the air. Daisies and poppies grow for choice above these ditches, and barrows and hill-top camps have thus been revealed by white and scarlet circles. "A single field which I have looked upon," we may say with Wordsworth (almost), "speaks of something that is gone; the daisy at my feet doth same tale repeat."

Lastly, the low shadows at sunrise and sunset e the outline of low banks in deep black. That is time to photograph lynchets. On a June morn before breakfast the greater part of Salisbury Plai seen to be covered with the banks of abandoned C fields; but afterwards they "fade into the comm light of day." The great ramparts of hill-top can are strong enough to throw a shadow even at m day, but they are best photographed when the sun low, for then not only do the ramparts stand out b but the banks and pits of the habitations also.

Air-photography has only recently been harnes to the chariot of archæology; but it has already fou a generous and enthusiastic patron in Mr. Alexan Keiller, and its future is assured.

Obituary.

MR. OTTO HEHNER.

A NOTICE of the scientific career and work of Mr. Otto Hehner, whose death is announced, will be practically the history of English Analytical Chemistry during the past fifty years.

Born at Marienberg in 1853, and educated at Wiesbaden under Fresenius, Hehner came to Britain in 1873 as assistant to Bischof at the Andersonian College, Glasgow, where he had Ramsay for a colleague. In 1874 he became assistant to Arthur Hill Hassall, who was prosecuting researches, largely microscopical, into the composition of foods, and on the means of detecting adulterations, and it was here that Hehner worked out his methods of butter analysis, far in advance of the knowledge of the day, and the foundation of modern methods; by this research he won his spurs and established his reputation for original thought. In 1877 he moved to London and established a consulting practice, which in 1881 was removed to 11 Billiter Square. Problem after problem was tackled, and Hehner's publications, chiefly in the *Analyst*, and the Journal of the Society of Chemical Industry, show t varied scope of his investigations, beeswax, glyceri oils and fats being but a few of the subjects in whi he was a pioneer worker.

Hehner was a very active member of the Society Public Analysts, and though not an original membe he was early (1883) elected secretary, and was preside in 1891. His association with the Institute of Che istry was nearly as intimate; elected a fellow in 187 he was one of the leaders of the movement that 1887 enlarged the scope of the Institute by removi the narrow restrictions of membership, and started t gradual raising of the professional status of t analytical profession by making the essential qualific tions more real. Hehner's appointment as examin to the Institute in 1895 was the real commencemei of a genuine test of knowledge in analytical chemistr and to him also the foundation of the library of t Institute is due; he filled the office of vice-president three separate occasions and was censor in 1901 to 190

Hehner held many appointments as public analyst

indeed, was more proud of this title than any title. In almost every branch of the analysis of food and drugs he has left his mark. As a witness he was superb; in the box he told a plain unvarnished tale in perfect English (although he never lost his accent), and compared conviction. Before parliamentary committees also he placed his wide knowledge, and there is no doubt but that his evidence had a distinct influence on legislation, and his expert advice was welcomed in many quarters.

During the War, Hehner devoted himself wholeheartedly to the country of his adoption; his expert knowledge of glycerin technology was placed at the service of the country without remuneration, and he served on various committees where his knowledge was invaluable. His reward was that some pettifogging local authorities removed him from his public appointments because of his German origin; how little they knew the man, who had given them such good service. Hehner was greatly hurt by this, and it affected his health; partly on this account, but chiefly to escape what he felt was an anomalous position, he went to South Africa in 1921, and though he came back, he paid another temporary visit, and died there on September 9 of a tropical fever.

Full of energy, kind-hearted and generous, especially to young men, a keen critic, and a strong fighter, but always in a fair and just manner, a firm staunch friend, a widely read philosopher, a genial companion, he had that strong personality and marvellous intuitive power that marks a leader. H. D. R.

Mr. J. Britten.

THE sudden death of James Britten, fellow of the Linnean Society and for nearly forty-five years editor of the *Journal of Botany, British and Foreign*, occurred at Brentford on October 8. He was born at Chelsea on May 3, 1846, and became attracted to the study of plants from an early age. His earliest printed paper known to the writer is in the *Journal of Botany*, in the first volume of which, issued in 1863, is a short paper on "Rare and Exotic Plants at Kew Bridge." In 1865 he removed to High Wycombe, and the four years spent in that town gave him further opportunities for studying field botany.

Short papers came from Britten's pen quickly; then in 1869 he was appointed a junior assistant in the herbarium of the Royal Botanic Gardens, Kew. Two years later he was transferred to the Department of Botany, British Museum, then housed at Bloomsbury. In 1879 the senior assistant, Henry Trimen, proceeded to Ceylon, succeeding Thwaites at the botanical garden of Peradeniya, and Britten took his place as editor of the *Journal of Botany*, which he occupied until his death last week.

Britten's independent works were a quarto on "European Ferns," in 1881–82, a reprint of William Turner's "The Names of Herbes in Greke, Latin, Englishe, Duche and Frenche, 1548," with the identification of the plants, in 1881; a list of farming words, extracted from Wm. Ellis, in 1880; and the determinations of Banks's plants issued in folio by the Trustees of the British Museum, in 1900–1905. With Robert Holland he brought out "A Dictionary of English Plant Names," 1878–84; and with Prof. Boulger "A Biographical Index of British and Irish Botanists," 1893, with three subsequent Supplements to 1908; a second edition is understood to be ready for press.

Britten, however, was better known as a keen debater and critic, in his own journal, and the number of his essays, long or short, is great. He was quick to detect the weak side of an adversary, and unsparing in attack. For many years he took an active part in the work of the Catholic Truth Society, in recognition of which he was made a knight of the order of Saint Gregory in 1897, by Pope Leo XIII., and knight commander (K.C.S.G.), *con placca*, in 1917. B. D. J.

Prof. H. Kraemer.

THE death on September 9 of Prof. H. Kraemer at Detroit, which has robbed pharmacognosy of one of its most brilliant exponents, will be much deplored by his colleagues not only in the United States but also throughout the scientific world generally. Henry Kraemer was born on July 22, 1868, and studied at the Philadelphia College of Pharmacy while still an apprentice in a pharmacy in that city. In 1889 he graduated in pharmacy there and afterwards took the degree of Bachelor of Philosophy in the School of Mines of Columbia University. He was then appointed professor of botany and pharmacognosy in the School of Pharmacy of the Northwestern University. He studied for an additional year in Marburg, chiefly under the late Prof. Arthur Meyer, and obtained the degree of Ph.D. Soon after his return to America he was called to fill the chair of botany and pharmacognosy in the Philadelphia College of Pharmacy, a position which he continued to hold until 1917, when he was transferred to a similar position in the University of Wisconsin.

From 1899 to 1917 Prof. Kraemer was the editor of the *American Journal of Pharmacy*. During this time he exhibited indefatigable industry, not only in his capacity as editor but also as research worker in the laboratory, mainly in the fields of botany and pharmacognosy. He also took an active part in the revision of the United States Pharmacopœia as chairman of the sub-committee on botany and pharmacognosy. In Great Britain he was best known by his "Scientific and Applied Pharmacognosy" and "Applied and Economic Botany," his ability receiving recognition by his appointment as honorary member of the British Pharmaceutical Conference. Prof. Kraemer exercised a widespread influence, particularly in America, by his industry and by the stimulus he imparted to others by the example he set. He was an independent thinker and gave fearless expression to his thoughts, a trait which made correspondence with him a sincere pleasure. His loss will be keenly felt.

WE regret to announce the following deaths:

Lord Abercromby of Aboukir and Tullibody, formerly president of the Society of Antiquaries of Scotland and honorary member of the Finno-Ougrian Society of Helsingfors and of the Finnish Archæological Society, on October 7, aged eighty-three.

Dr. W. B. Hemsley, F.R.S., formerly Keeper of the Herbarium, Royal Botanic Gardens, Kew, on October 7, aged eighty.

Current Topics and Events.

WE have received under the designation of "Commission F (Propaganda)" what is apparently a proposal emanating from the Twenty-third World Peace Congress to the Commission for Intellectual Co-operation of the League of Nations. We forbear to reproduce the language of this document, which has evidently been written under strong emotion. After an allusion to the fact that science often places its work at the service of war and destruction, a further allegation is made that science is frequently governed by a spirit of national hostility and narrow-mindedness, accompanied by the oppression and persecution of savants "who expressly profess another opinion." The wording of this document is not felicitous, but the meaning and purpose are tolerably clear. The Commission for Intellectual Co-operation will certainly have the goodwill of the British scientific world in its efforts to divest science from all its misuses by man, and in all efforts towards promoting international amity. We think, however, that the document before us greatly overstates the case and does much less than justice to the international sympathies that have existed and have been fostered in the scientific world. We certainly know nothing of international oppressions and persecutions following upon conflicts of opinion; we should rather have said that, before the War, the nations had nowhere reached a sense and condition of brotherhood more real than in the world of science. Not only was there a pooling of all new knowledge, but there were also numerous international organisations for co-operative scientific investigation and for deliberative and social intercourse. Few men of science in modern times have attained maturity without finding themselves linked by strong ties of friendship to a multitude of foreign fellow-workers. Certainly there are sometimes acute differences of opinion between two men of science, or it may be two schools of thought in different countries, but we have no knowledge of any oppression or persecution arising here any more than among men of the same country.

THE dictum that "for the chemist there are no waste products" is well illustrated by the exhibition which British Glues and Chemicals, Ltd., is holding in its research department at 19 Bedford Square, London, W.C.2. Although bones were used for many purposes by primitive man, and glue is said to have been first prepared from them by Papin in 1680, no industry of any importance based upon their utilisation was initiated until about a century ago. Since then the number of products made from bones has increased considerably and the quantity of bones consumed has multiplied almost beyond measure. In addition to the manufacture of glue and gelatin, the extraction and preparation from bones of calcium phosphate, in various forms and degrees of purity, is a great and growing industry. This substance is used as bone-ash in the ceramic industry, and as bone-meal, steamed bone-flour, raw bone siftings, "dissolved" bones in agriculture. Recently pure finely ground steam bone-flour, containing 65 per c tricalcium phosphate and 10 per cent. calcium bonate, has come into prominence as a food for fa stock. Other useful products obtained from bo are fat for soap and candle manufacture, ani charcoal, bone oil and pitch, and ammonium sulph A large variety of substances and commodities shown in the exhibition, and in many cases us explanatory data are added.

AT the opening meeting of the new session of Society of Chemical Industry (Manchester sectic Mr. W. J. U. Woolcock, president, gave an addr on the benefits that accrue from close co-operation the scientific and industrial branches of chemist The impetus to co-operation given by the War now passed, and we are in danger of retrogressi Lack of understanding between scientific worker a industrialist may be due to weaknesses on both sic The former is apt to forget that common sense is of more important than scientific knowledge; the lat to regard pure and applied science as unrelated sphe of activity, and to consider research in pure scie as wasted effort, particularly when times are b Members of both branches are prone to take on w for which they are not fitted by nature. It is revolutionary discoveries, especially in pure scien that we must look for help. The Association British Chemical Manufacturers has had an educat influence on the less enlightened manufacturers; working for the advancement of chemical industry helps to open up better prospects and bring ab better conditions of employment for the chemist, a by effecting successful co-operation among chemi firms, it fosters co-operation between the technical a non-technical branches of the same firm. The org isation of the chemical and other scientific exhibits the British Empire Exhibition is a splendid exam of the successful co-operation of scientific and dustrial workers.

AN archæological discovery of the highest impo ance for Indian prehistory has been made at Mohen Daro in Sind and at Harappa in the Punjab. Benea strata belonging to the Kushan culture of the seco century B.C. have been found remains of massive bri structures and a number of objects, including n types of pottery, plain and painted and both han and wheel-made, bangles of glass, paste, and she stone rings of unknown use, knives and cores of che and oblong bars of copper, assumed to be coins. number of seals, of ivory, paste, stone, and steatite, a engraved with an unknown pictographic script a figures of unicorns and bulls, in a style unknown Indian art. The absence of iron, except in the late strata, and the scarcity of metal indicate an early dat Sir John Marshall, Director-General of Archæolo in India, in describing the discovery in the *Illustrat London News* of September 20, points out the affiniti of the script to pictographs from the Mediterranea area of Mycenean age; but he is of the opinio that this culture developed in the Indus valley witho

serous modification by outside influence. Prof. Sayce, in commenting on the discovery in the issue of December 27, points out that the inscribed seals are practically identical with the Proto-Elamite "tablettes de comptabilité" found by de Morgan at Susa, and indicate intercourse between Susa and North-West India in the third millennium B.C. In the same journal on October 4, Messrs. Gadd and Sidney Smith of the British Museum described in detail, with numerous illustrations, the parallels to be found in the objects from both the sites and from Babylonia, their conclusion being that the makers of the seals were in close touch with the Sumerians and had borrowed their artistic style and the basis of their script from them somewhere about 3000–2800 B.C.

THE harbour at Esquimalt, B.C., was formerly well known as the North Pacific Naval Station, directly under the Admiralty, but is now under the Canadian Department of National Defence. The graving dock, built in 1887 by the Canadian Government, has been in constant use, but the need has been felt for something better able to cope with naval and merchant vessels of modern size, and the Federal Government decided in 1920 to construct a new dry dock. An illustrated account of this dock appears in *Engineering* for September 26, from which we learn that the dock will accommodate the largest class of ships, a depth over sill at high tide of 40 ft. being provided, while the maximum usable length will be 1150 ft. The width at the entrance at coping level is to be 135 ft. and on the sill level 107 ft. 1¾ in. To the west of the dock there is a landing wharf 800 ft. long. The main pumping plant will consist of three 42-in. centrifugal pumps direct-connected to vertical-shaft induction motors of 1000 horse-power. Eight capstans will be provided on the dock side and one at the end of the chamber. The former will have a full-load capacity of 25,000 lb. at 12 ft. per minute, and the latter a capacity of 65,000 lb. at the same speed. The construction is now well advanced and it is hoped to complete the undertaking this year. Whilst the Government Department will undertake docking and undocking, shipowners will make their own arrangements with repair firms for carrying out work on vessels while in dock.

FLOODS in India are rapidly subsiding, according to detailed information given recently in the *Times*. In northern India an improvement in the railway situation is reported, although some weeks must elapse before thorough working is restored; many important towns are entirely cut off from railway service. The roads have also been affected by the floods, and many railway bridges have been destroyed. In Delhi the floods are said to be unprecedented in living memory, and the records show that the Jumna at Delhi rose inches higher than the level of the last great floods in 1906. In the Karnal district of the Punjab 20 villages are affected, and of these 60 are said to have been destroyed. The floods of the Ganges have done considerable damage in the district of Cawnpore, where the river level is higher than has ever been recorded. At the end of September the rainfall was excessive; in 2 days the amount reported was 15 inches at Mussooree and 13 inches at Meerut. At Simla continuous rainfall was reported for 72 hours, commencing at midday on September 27.

PROF. H. B. DIXON, honorary professor of chemistry in the University of Manchester, will deliver the inaugural lecture on "The Life and Work of Ludwig Mond," in the Chemistry Theatre of the University of Manchester on Monday, October 20.

APPLICATIONS are invited for an assistantship in the Technical Records Section of the Admiralty. Candidates must have a sound knowledge of modern physics and be able to read technical French and German and have some bibliographical experience. Applications must be sent by, at latest, November 10, to the Secretary of the Admiralty, C.E. Branch, Whitehall, S.W.1.

A DIRECTOR of the Laboratory of Microbiology and Pathology, Department of Public Health, Brisbane, is shortly to be appointed. Applications for the post are invited from holders of the diploma in public health with recent special laboratory experience in microbiology. The latest date for the receipt of applications, which should be sent to the Agent-General for Queensland, 409 Strand, W.C.2, is October 27.

Two research assistants, a senior and a junior, are required by the National Federation of Iron and Steel Manufacturers, Caxton House, Tothill Street, S.W.1, for research work on blast furnace reactions at the Imperial College of Science and Technology, under the direction of Prof. Bone. Candidates must possess a good knowledge of physical chemistry, gas analysis and manipulations. Applications must reach the director of the federation by October 27 at latest.

THE new weekly journal entitled *East Africa* is devoted to the interests of east and central Africa. It makes a good start with an attractive number that contains several interesting articles, including one on cotton production in the Sudan and another on the pastoral and agricultural possibilities of the highlands of Kenya, Uganda, and Tanganyika. The journal promises to be of value to all interested in the development of the lands of East Africa.

THE Air Ministry has announced that the two-seater dual control light aeroplane competition, which concluded at Lympne on October 4, has resulted in the production of new aeroplanes and engines of great interest and value from a practical and technical point of view. The aeroplanes, which were all widely divergent in design, proved themselves to be thoroughly efficient and satisfactory, and the power plant showed itself capable of carrying out all the tests prescribed, including the ten hours' reliability test. On the other hand, it was found necessary to run the engines at such a high speed in order to secure the maximum competition performance, that trustworthiness suffered. The Air Ministry is therefore reviewing the whole of the engine position with the view of obtaining the necessary technical data,

free from the adverse conditions inherent in a competition of this nature.

THE Paris correspondent of the *Times* states that M. Callizo, the French airman, has created a world "record" for altitude by reaching the height of 11,841 metres (38,843 ft.) in a flight made on October 10. M. Callizo's barogram has been verified at the École des Arts et Métiers. The previous record was held by M. Sadi-Lecointe, who reached a height of 35,239 ft. at Villesauvage, France, on September 5, 1923.

THE "Cobb" lectures, which were delivered before the Royal Society of Arts in March and April of the present year by Dr. T. Slater Price on "Certain Fundamental Problems in Photography," are published in full in the Society's Journals for September 5, 12, and 19. The three lectures form a concise but comprehensive statement of the present state of knowledge concerning the gelatino-bromide photographic plate. Dr. Slater Price deals first with gelatin and especially its physical properties and matters related thereto. He passes on to the colour of silver deposits produced in gelatin films by photographic processes, the nature of the developable as well as of the printed out image, the theories of the nature of the action of light and the "centres" of sensitiveness in the grains, and other matters. Those interested in these things will find it a great help to have the various results brought together as they are here, with the valuable critical and comparative rema of the lecturer.

THE latest catalogue of Mr. F. Edwards, 83 H Street, Marylebone, W.1 (No. 462, British Emp Series, No. 5), deals with books, engravings, drawin and maps relating to Canada, West Indies, Brit Guiana, and Falkland Islands.

WE have received from Mr. W. H. Robins Nelson Street, Newcastle-upon-Tyne, a copy of catalogue No. 11, 1924, of second-hand books. T catalogue, which is of a miscellaneous character, c tains the titles of a good many works likely to inter readers of NATURE, *e.g.* a section is devoted to bo illustrated by Thomas and John Bewick, and oth to botany, natural history, folklore and archæolo The prices asked appear to be reasonable.

A NEW book by Prof. Ellsworth Huntington announced by Charles Scribner's Sons. It is entit "The Character of Races: their Formation a Modification by Environment," and is a study the ways in which racial character is moulded a modified by environment. Another book in the sa publishers' announcements is "Racial Realities Europe," by L. Stoddard. In this volume the follo ing subjects are dealt with: racial realities, kindr Britain, the Nordic North, composite France, t Mediterranean South, Alpinised Germany, disrupt Central Europe, the Alpine East, the Balkan flu Turkey, Arab lands, and the new realism of science

Our Astronomical Column.

COMETS.—Encke's Comet has brightened remarkably, and is now on the verge of naked-eye visibility. A photograph by Mr. G. Merton shows a short tail. It is 138 years, or 42 revolutions, since the comet was first seen, but the loss in brightness during that period is not noticeable, in spite of the small perihelion distance. Some thirteen years ago the late Mr. W. T. Lynn suspected that the comet was fading, but the loss of light, if present, was only temporary.

Dr. W. Baade succeeded in photographing Reid's Comet, 1924*a*, on September 27 with the Bergedorf reflector. It was of magnitude 16 as compared with the calculated magnitude 10, indicating great physical loss of light. The position was within 4′ of the Copenhagen orbit.

MARS.—*L'Astronomie* for August contains several drawings of the planet Mars, made during June and July. The southern hemisphere was then in its spring, the summer solstice being passed on September 30. The southern polar cap was large and showed much interesting detail. It was crossed by two large dark rifts, and the region Argyre on its edge was brighter than the rest of the cap.

M. Antoniadi, who has been observing with the 30-in. Meudon refractor, gives a series of measures of the size of the polar cap in the *Comptes rendus* of the Paris Academy of Sciences for September 22. Several years ago he contributed a paper to the Royal Astronomical Society indicating that the size and rate of melting of the cap vary with the solar cycle. The size is greater and the melting slower in times of sunspot minimum and diminished radiation. It is noted that the present results are in full acco with this, and that the late winter and spring of t Martian southern hemisphere appear to have be colder than the average.

THE SPIRAL NEBULÆ.—Dr. K. Lundmark co tributes a paper to the *Observatory* for Septemb dealing with the radial velocities and proper motio of the spiral nebulæ. He includes some nebulæ the class described by Reynolds as globular, sin they share the high radial velocity. He finds t following values for the solar apex and motion:

(1) From the radial velocities of 43 spirals—

R.A. of apex . .	$20^h{\cdot}3 \pm 3^h$
Decl. . . .	$+75° \pm 30°$
Velocity . . .	651 ± 135 km./sec.

The large K term of $+793 \pm 88$ km./sec. is indicated

(2) From the very small and uncertain prop motions of seven spirals—

R.A. of apex . .	$1^h{\cdot}7 \pm 5^h$
Decl. . . .	$+63° \pm 46°$
q	$0{\cdot}0074'' \pm 0{\cdot}0055''$.

Deduced mean distance of spirals 61,000 light years

No allowance has been made for proper motion comparison stars, which were of about magnitude 1

The two positions of the apex do not differ mo widely than we should expect from the large probab errors. Both R.A. and Decl. are considerably larg than the values, 18^h and $+30°$, given by the near stars, suggesting that the whole group of stars rou the sun is drifting relatively to the group of nebulæ

Research Items.

REHISTORIC IVORY FIGURINE FROM EGYPT.—ng the more important objects discovered by the ish School of Archæology at Qau in Egypt during theexcavations of last season was a female figure rudly carved in ivory. It differs from any of the prehisric ivories hitherto known. On the same site we found ripple pottery and a number of objects—a gbular vase with four small handles, a long narrow ate, a flint dagger, and a small oval vase with cylidrical neck, all of types not previously known. It ould appear that these finds represent a culture apt from the usual prehistoric Egyptian, though on uth the same level and using the same materials but in different way. The ivory figure is not of the steopygous type. The arrow heads and other flint wor point to a connexion with the makers of the Faum desert flints, which are of Solutrean style. Sir Fliders Petrie in describing these finds in *Ancient Egbt*, 1924, Pt. ii., suggests that the culture may have oriinated in Central Asia, whence the Solutrean wokers are supposed to have come. This civilisation, forwhich the name Badarian is suggested provisionall from Badari, the district around Qau, would thus be the earliest of any known in Egypt, though not necssarily contemporary with the European Solutrn period.

URRENCY OF THE GUPTA DYNASTY IN EASTERN INIA.—In the course of some notes on the Gupta an later Gupta coinage in the Journal of the Asiatic Sciety of Bengal, N.S., xix., Pt. 6, Mr. N. H. Bittasali discusses the origin of the so-called "nitation Gupta coins." These coins are of base gol and approximate to a standard of 95 grains, coiderably less than the Gupta standard. They wre in circulation in Eastern India only. Although thy cannot be attributed to the Gupta imperial dyasty, it is evident that they were issued by a faily which had a veneration for Gupta traditions. Its also evident that the king who was responsible fotheir issue claimed paramount power in virtue of th performance of the horse sacrifice. This would pot to the first king of the Gupta dynasty of Mgadha, Aditya Sana Deva, who rose to power after th death of the last sovereign of the imperial line, wh which he was connected, and is known to have celebrated the horse sacrifice. The fall of the Mgadha dynasty was followed by a period of anrchy in which all knowledge of arts and crafts was lo:, so that when the Mohammedans first entered Bgal they found that the only currency in use cosisted of cowrie shells, no minted money having bn struck for four centuries.

PRAKRIT AND SANSKRIT LINGUISTICS.—Sir George Gerson has won for himself a world-wide reputation b a long series of masterly works upon the languages oHindustan, culminating in the magnificent "Lingstic Survey of India" published by him for Gvernment, and now happily almost completed. Hs latest contribution to these studies is "The Pkrit Dhātv-ādēśas according to the Western and th Eastern Schools of Prakrit Grammarians," published in vol. viii., No. 2, of the Memoirs of the Atic Society of Bengal. As is generally known, the mdern Aryan languages of India are all derived from t ancient dialects represented in literature by the Vdic and Sanskrit. The intermediate links were the Pkrits or ancient forms of popular speech, which in tir turn were cultivated for literary purposes and sdied by many grammarians, whose surviving vrks, so far as they are known, fall into two classes, an Eastern school, deriving from Vararuci and his successors, and a Western school, based upon Hēmacandra. The present work deals with the verbal roots which are specifically recognised by the grammarians as used in Prakrit and as differing from the corresponding Sanskrit roots. It consists of two indexes: the first of these contains the Prakrit roots arranged alphabetically, in the order of their Sanskrit forms, in parallel columns showing the respective paradigms quoted by five leading native grammarians, while the second presents the roots arranged in their own alphabetical order with parallel columns showing the various meanings assigned to them by the same grammarians. It is rounded off by an introduction and an appendix containing the text of a chapter on the same subject from the Prākṛita-kalpataru, a Sanskrit grammar by Rāma Śarman, and altogether will be of the greatest utility to students of the ancient literary Prakrits and the modern vernaculars of India.

CONTROL OF PESTS IN GLASS-HOUSES.—The Annual Report for 1923 of the Experimental and Research Station at Cheshunt gives a record of steady progress and widening scope of activity. The variety and manurial trials with tomatoes have been revised to bring them more into line with present-day requirements, and valuable results are anticipated. A definite relation has been determined between manurial treatment and blotchy ripening of fruit, the proportion of blotchy fruit being heavy when the soil is deficient in both nitrogen and potash, and reduced when these substances are added to such soil. Experiments on the destruction of red spider by fumigation indicate that the action of gases and volatile liquids is ineffective owing to their rapid escape from the atmosphere in glass-houses and owing to the difficulty of keeping up a comparatively high concentration of the vapour sufficiently long to kill the spider. As recorded by Messrs. E. R. Speyer and O. Owen in NATURE of June 7, p. 820, naphthalene, when heated, seems to be the type of fumigant best suited to the purpose, provided that, within broad limits, the amount of its vapour in the atmosphere can be controlled so that no injury is caused to the plant. Other tests show wood-lice can be controlled by the introduction of small quantities of phenol into the soil, but unless commercial phenol can be utilised, the method is too expensive for ordinary use. In view of the suggested fertilising value of increased quantities of carbon-dioxide in the air of glass-houses, continued experiments have been made to overcome the technical difficulties involved in the control of the concentration of the gas, and increased yields of tomatoes have been obtained in certain cases, encouraging further research on the subject.

SURFACE TENSION OF SPRAY LIQUIDS.—In the control of insects by poisonous sprays, the power of the liquid used to wet and spread over the surface to which it is applied is as important a factor as its toxicity to the organism against which it is directed. Woodman (*Journ. of Pomology and Horticultural Science*, iv., No. 1) has now shown by carefully devised physical experiments that the surface tension of a spray liquid may be reduced to a certain critical value by the addition of small quantities of soap, under which conditions the surfaces of leaves are easily wetted and the maximum amount of spray liquid retained by them. Further reduction of surface tension increases the "spreading power" of the spray though not its "wetting power." Increases of viscosity by the

addition of gelatine at about 0·3 per cent. concentration causes the retention of much more of the spray fluid on account of the adsorption of gelatine by the leaves. Forcible spraying, when the drops pass rapidly through the foliage, also augments retention. By measuring the areas of spread of lenses of liquids on wax surfaces, it has been determined that the reduction of surface tension of the spray fluid below 32 dynes/cm. greatly increases the area of spread. This indicates the economic advantage of soap as a "spreader," owing to the very low surface tension of dilute soap solutions. The greatest spread is obtained with small drops applied with considerable force, which supports the advocated practice of mist-like spraying, though it is pointed out that reduction in the size of drops would lead to decreased "force" in passing the leaves and so to a lessened retention of the spray liquid.

WATER ABSORPTION BY COCO-PALMS.—The *Philippine Journal of Science* for July 1924 contains a paper by Messrs. R. B. Espino and J. B. Juliano dealing with the rate at which roots of *Cocos nucifera* (*in situ*) absorb three- or four-salt culture solutions. The solutions absorbed most rapidly are characterised by a rather high proportion of magnesium sulphate. In this respect the results resemble those previously obtained for rice, except that the latter apparently requires less concentrated culture media. Maximum absorption in the coco-palm takes place between one and two o'clock in the afternoon, and it is shown that variations in the rate of absorption correspond quite closely to variations in the rate of transpiration. The apparent width of the leaf pinnæ is inversely proportional to the rate of absorption. The fact that water absorption depends upon the evaporating power of the air leads the authors to suggest that successful cultivation of this palm is possible even in climates usually regarded as too dry, if soil moisture is supplied in sufficient quantity.

THE GENETICS OF TOBACCO.—While parthenogenesis has been known to occur in two varieties of *Nicotiana Tabacum* grown in England, various tests have shown that this process is almost unknown in North America. The question has been re-examined at Pusa by Messrs. G. L. C. Howard and Kashi Ram (Mem. Dep. Agric. in India, Bot. Ser. 13, No. 1), who were unable to obtain evidence of parthenogenesis in either of the varieties tested. Parthenocarpy, however, occurred in *N. Tabacum*, var. *Cuba*, this always being associated with white flowers and also with especially vigorous growth of the parent plant. The inheritance of characters in Indian varieties of *N. rustica* has also been studied by G. L. C. Howard, and the results are described in the same number of these memoirs. Neither parthenogenesis nor parthenocarpy were observed. The characters of the F_1 plants were intermediate between those of the parents, except that the average height was always greater than that of the taller parent. The difference between short and tall types appears to be due to a single factor which causes elongation of the internodes both of the stem and of the inflorescence. A frilled leaf margin is dominant to a smooth edge and is apparently associated with the presence of a single factor.

RAINFALL MAP OF SWEDEN.—Owing to the widespread distribution of rainfall stations in Sweden which has grown since the start of the Hydrographic Service in 1907, it has been found possible to produce a rainfall map of the country with much greater accuracy than of old. Nederbördskartor över Sverige by Axel Wallen appears as Band 2, No. 3 of *Meddelanden från Statens Meteorologisk-hydrografiska Anstalt*. It contains a map of the annu rainfall based on the figures from 1881 to 1920 a twelve maps of monthly rainfall. In the nort where stations are few, the records probably do n express the full value of the fall and they have be adjusted by data derived from the flow of river In the north-east, such corrections should probabl also be made, but the figures do not appear to b available. The paper contains a summary of th data employed and a discussion of the cartograph methods employed. The Swedish rainfall figur for 1923 are published by the same department Aarsbok. 5. The volume includes rainfall maps f each month of the year 1923.

EXPERIMENTS ON A MERCURY ARC RECTIFIER.—In the *Zeitschrift für Physik* for August 8, Messr W. Schottky and J. von Issendorff describe exper ments designed to elucidate the peculiar effect pr duced when different voltages are applied to the wa of a mercury arc rectifier. The current curv obtained with a probe electrode was quite similar t that with the rectifier; when the electrode wa 12·2 volts above the cathode voltage, the current, flowing from the discharge into the electrode wa zero; but it very rapidly increased, as the voltag diminished, towards a saturation value. The greate part of the rise of current took place between +12· and zero volts, after which down to −100 volts rose very slowly indeed. To determine the nature this current, the authors measured the heating effe produced by it in the probe electrode, by means an auxiliary heating coil, insulated in such a wa that the whole of the heat produced by it went int the electrode. In this way the watts required to giv the temperature rises produced by the current I a different voltages were determined, and it was show that, with constant current through the electrod the connexion between the heat produced and th voltage was a linear one. The relation was suc that, within the limits of accuracy of the measure ments (about 20 per cent.), it can be stated that th subsidiary current is due entirely to the flow positive ions into the electrode. There is therefor no secondary production of cathode rays in the regio examined. There is a distinct dark space round th probe, which only vanishes when it is made the anod The suggestion previously made, that measurement of potential in the mercury arc with a probe ar several volts too low, is confirmed.

THE EMISSION OF ELECTRONS CAUSED BY α-RAYS —Dr. A. Becker has carried out a very comprehensiv investigation on this subject, in which the phenomen were studied in high vacua. The α-rays were sen through foils of different thicknesses of aluminium silver, and gold, and the movements of the electron were controlled by fields of different signs and differen intensities, produced between an electrode consistin of the preparation holder and foil and a surroundin electrode, or a parallel plate (*Annalen der Physik* September). About ten electrons were produced pe α-particle, when this had the velocity $1{\cdot}5 \times 10^9$ cm per sec., and about twenty with half this velocity using any of the three metals. It was shown that th emission requires no essential outside acceleration, s that the electrical method employed in determinin the velocities of the electrons, or δ-rays, is good i principle. Using a central field (an outer spherica electrode with the preparation holder at the centre the curve of velocity distribution is very similar t that of the electrons from an incandescent solid, bu varies from this at high velocities, which are mor

...cent in the first curve than in the second. Within ...imits of experimental accuracy, the first curve ...s with the Maxwell law of velocity distribution. ...e results were confirmed by experiments using ...geneous fields between two parallel condenser ...s. It is probable that the distribution of velocity ...lependent of the direction of emission, and that ...distribution in different directions follows the ...e law. The distribution of velocity, and its ...lute value, are independent of the nature of the ...l employed and of the velocity of the α-rays. ..." most probable " velocity corresponds to a ...tial drop of about two volts; higher velocities ... those corresponding to about twenty volts cannot ...certainty be shown to exist. The results make ...certain whether the two kinds of electron emission ...tioned can be regarded as due to the same funda...tal mechanism.

SINTERED GLASS FILTERS.—The *Chemiker Zeitung* ...4, vol. 48, p. 693) contains an account of the tests ...ed out by Moser and Maxymowicz at the Tech...ne Hochschule, Vienna, of the new glass-filters ...e by the well-known Jena firm of Schott und Gen. ...se filters are an improvement upon the asbestos ...s of the Gooch crucible, since the glass filtering ...r is fused into the glass crucible, the lower rim of ...ch projects beyond it for protection. Various ...les are made according to the fineness of the ...ipitates to be collected. Successful quantitative ...s were carried out with silver chloride, lead sul...te, lead chromate, mercuric sulphide, cuprous ...cyanate, nickeldimethyl glyoxime, barium sul...te, calcium oxalate, etc. The calcium oxalate ...be weighed as $(COO\,Ca)_2 . H_2O$ and attempts are ...g made to estimate various metallic ammonium ...sphates as such. The filters were found to resist ...action of dilute and concentrated acids, including ...a regia, but are readily attacked by alkalis. ...eous ammonia can, however, be used. The main ...dvantage lies in the fact that variations of as much ...0·4 mgm. were found in the weighings unless the ...cibles were allowed to stand for several hours in ...desiccator.

CHEMICAL CONSTANTS.—In the April-July volume of ... *Compte rendu des Séances de la Société de Physique,* ...Geneva, the question of the calculation of the ...ropy of a gas from the point of view of the quantum ...ory is discussed by A. Schidlof. It is pointed out ...t the problem involves the quantification of the ...rgy of translation of the gas molecules, and the ...iculties arising out of this are mentioned. In the ...e of a gas consisting of N molecules in a volume V, ... volume V/N may be taken as that in which the ...antified motion takes place (Sackur), or, alterna...ely, the cube of the mean free path (Schrödinger). ...ere is only one case free from ambiguity, namely, ...en the volume V contains only one molecule which ...n assume all the states of motion compatible with ... conditions imposed. With this case, an expression ... the entropy is found containing an additive con...nt, and it is claimed that neither Nernst's theorem ...r the quantum theory allows of this constant being ...glected. In the calculation of the chemical con...nt of a monatomic gas, the number N does not ...pear in the result, and the author shows that it ...also unnecessary to introduce it into the deduction. ...e formula is that of Sackur, and differs from that ...nd by Tetrode and by Planck.

THE COMPOSITION OF CHROMIC ACID.—The hydra...n product present in an aqueous solution of chromium trioxide has usually been supposed to be dichromic acid, $H_2Cr_2O_7$, on the basis of the colour of the solution and conductivity measurements combined with cryoscopy. In the August number of the Journal of the Chemical Society, Mr. H. T. S. Britton describes some measurements with the hydrogen and oxygen electrodes in solutions of chromic acid which lead to the result that the acid is H_2CrO_4, dissociating in two stages: $H_2CrO_4 \rightleftharpoons H^{\cdot} + HCrO'_4 \rightleftharpoons 2H^{\cdot} + CrO''_4$. The first stage is almost complete in dilute solutions; the second dissociation constant is very small, $4{\cdot}4 \times 10^{-7}$ at 18°. The use of the oxygen electrode as an indicator of both hydrogen ion concentrations and as end-points in titrations was made possible by comparison with the hydrogen electrode, and the method used appears to offer possibilities of application in other fields.

ATOMIC WEIGHT OF ALUMINIUM.—The June issue of the Journal of the American Chemical Society contains a description of the analysis of aluminium chloride by H. Krepelka, of the University of Prague. In a previous determination, with Prof. T. W. Richards, the value 26·963 was found as a mean of four analyses of aluminium bromide, the value given in the International Tables being 27·0. In the present research, pure aluminium chloride was synthesised from very pure chlorine and the purest obtainable aluminium. Eleven different fractions of the chloride, digested and repeatedly sublimed in nitrogen and in a vacuum, were analysed. The ratio $AlCl_3 : 3Ag$ was determined, with three different samples of standard silver. The mean of the eleven determinations is $Al = 26{\cdot}972 \pm 0{\cdot}001$, with $Ag = 107{\cdot}88$ and $Cl = 35{\cdot}458$. The most probable figure is considered to be the mean value of 26·963 and 26·972, namely, 26·97. It is remarked that, according to Aston, aluminium is a pure element, of mass 27, its nucleus being composed according to the scheme $4n + 3$. The new result confirms the previously accepted value of slightly less than the sum of the nuclear masses of helium (4·00) and hydrogen (1·008), and although the three hydrogen nuclei are satellites, the new value suggests a slight loss of mass due to the disturbing effect of electromagnetic forces within the nuclear system.

PSEUDO-EPIBERBERINE.—In the August number of the Journal of the Chemical Society, Buck and Perkin describe experiments which involve at one step the condensation of 1-homopiperonyl-6 : 7-dimethyltetrahydroisoquinoline with methylal, under conditions the same as those previously used by Pictet and Gams. Crystalline products, however, could not be isolated. When the methyl alcoholic solution was treated with formaldehyde, the formyl derivative separates as a gum, and on warming with hydrochloric acid, this is at once converted into the sparingly soluble salt of what was anticipated would prove to be tetrahydroepiberberine. It was proved conclusively that this was not the case, and that the mode of condensation assumed by Pictet was incorrect. The isomeric alkaloid produced is called tetrahydro-pseudoepiberberine. For example, when treated with sodium hydroxide, the substance decomposes into oxypseudoepiberberine and dihydro-pseudoepiberberine, a reaction exactly analogous to one previously investigated in which epiberberinium chloride is converted into oxy-epiberberine and dihydro-epiberberine. In the same journal, Haworth, Perkin, and Rankin show that a similar state of affairs exists with respect to berberine, and that the tetrahydroberberine described by Pictet and Gams is probably not that substance, but an isomeride.

International Mathematical Congress.

THE International Mathematical Congress at Toronto opened on Monday, August 11, with a speech of welcome to the assembled members by Dr. H. S. Beland, Minister of Soldiers' Civil Re-establishment and Health. Dr. Beland, who spoke in English and French, conveyed to the mathematicians greetings from the Premier of the Dominion of Canada, who unfortunately found himself unable to be present. Sir Robert Falconer, president of the University of Toronto, also gave a brief speech of welcome. Prof. J. C. Fields, chairman of the organising committee, and Prof. C. de la Vallée Poussin, president of the International Mathematical Union, addressed the meeting. Prof. G. Koenigs, general secretary of the International Mathematical Union, assisted by Prof. W. H. Young, read a list of delegates to the Congress. This list was only provisional, since much of the information with regard to delegations was not available at that time. The large number of delegates officially appointed to represent governments, learned societies, universities, and other institutions was a distinctive feature of this Congress in comparison with those previously held.

At the close of the opening session a general session was held for the election of officers. Prof. J. C. Fields was elected president of the Congress, and the following vice-presidents were elected: Prof. B. Bydžovský, Prof. F. M. Da Costa Lobo, Prof. L. E. Dickson, Senator F. Faure, Prof. H. Fehr, Prof. L. E. Phragmén, Prof. S. Pincherle, Prof. E. Schou, Prof. C. Servais, Prof. C. Störmer, Dr. W. Van der Woude, Prof. W. H. Young, and Prof. S. Zaremba. Profs. J. L. Synge and L. V. King were elected general secretaries.

The various sections held their opening meetings at 2.30 P.M. The following acted as introducers for the sections: Sect. I., Prof. J. C. Fields; Sect. II., Prof. J. L. Synge; Sect. III. (a), Prof. J. C. McLennan; Sect. III. (b), Prof. C. A. Chant; Sect. IV. (a), Mr. T. H. Hogg; Sect. IV. (b), Prof. T. R. Rosebrugh; Sect. V., Mr. Robert Henderson; Sect. VI., Dean A. T. De Lury. After the reading of papers before the sections the members of the Congress attended a garden party given by Prof. and Mrs. J. C. McLennan at the York Club. In the evening Prof. Carl Störmer of Christiania delivered a lecture on "Modern Norwegian Researches on the Aurora Borealis."

On Tuesday, August 12, the sections met at 9 A.M. In the afternoon Prof. F. Severi of Rome lectured on "Géométrie algébrique." After the lecture the members of the Congress were the guests of the Lieutenant-Governor and Mrs. Cockshutt at a garden party at Government House. In the evening there was a conversazione at Hart House, at which the members had an opportunity of inspecting this great centre of student social life in Toronto.

On Wednesday morning, after short sessions of the sections, M. E. Cartan lectured on "La théorie des groupes et les recherches récentes de géométrie différentielle." In the afternoon, at a special convocation of the University of Toronto, honorary degrees of Doctor of Science were conferred on the following members of the British Association and the International Mathematical Congress: Sir David Bruce, Prof. de la Vallée Poussin, Sir Charles Parsons, Profs. Koenigs, Stekloff, Severi, Sir Ernest Rutherford, and Sir John Russell. After the Convocation, the members were entertained by the University at a garden party. In the evening Prof. W. H. Young lectured on "Some Characteristic Features of Twentieth Century Pure Mathematical Research."

On Thursday, August 14, the members of the Congress crossed to Niagara and availed themselves of the kind invitation of the Hydro-Electric Power Commission of Ontario to inspect the generating plant at Queenston, being afterwards entertained at lunch as the guests of the Power Commission at the Clifton Inn, Niagara Falls. After viewing the Falls and the Rapids, the members returned by boat to Toronto.

On Friday, August 15, a general assembly of the International Mathematical Union was held for the election of officers. Prof. S. Pincherle, of Bologna, was elected president, and Prof. G. Koenigs, of Paris, general secretary. After this meeting, sessions of the sections were held, and in the afternoon lectures were delivered by Prof. L. E. Dickson, of Chicago, on "Outline of the Theory to Date of the Arithmetic of Algebras," and by Prof. S. Pincherle on "Opérations fonctionnelles." The members then attended a garden party at the Grange, given by the council of the Art Gallery, and in the evening the Hunt Club was kindly placed at their disposal.

On Saturday, August 16, the sections met at 9 A.M. At 2 P.M. a wreath was laid at the base of the Soldiers' Memorial Tower. At 2.30 P.M. Prof. J. Le Roux delivered a lecture, "Sur l'intégration des équations aux dérivées partielles par des intégrales définies." At 5 P.M. the closing session of the Congress was held. Prof. J. C. Fields, president of the Congress, expressed the thanks of the Congress to all those who by their generous hospitality or services had contributed to its success. Prof. S. Pincherle and Major P. A. MacMahon also spoke, and Prof. J. L. Synge, general secretary, reported on the membership of the Congress. The following resolutions were adopted by the Congress at the closing meeting: proposed by Prof. J. L. Synge (Toronto), seconded by Dr. B. Bydžovský (Prague), "That this International Mathematical Congress assembled at Toronto hears with pleasure that the Royal Irish Academy contemplates the publication of a collected edition of the works of Sir William Rowan Hamilton"; proposed by Prof. C. V. Raman (Calcutta), seconded by Prof. G. A. Bliss (Chicago), "That the best thanks of the members of the International Mathematical Congress are due to Dr. J. C. Fields and to all those mentioned by him as having contributed to the success of the Congress, and that this vote of thanks be communicated to them."

The members of the Congress and friends assembled for the last time at a dinner in Hart House on Saturday evening. Those members of the Congress who went on the western excursion with the British Association left Toronto on the night of Sunday, August 17.

Although the attendance suffered considerably from the fact that the Congress took place while many summer sessions in the universities of the United States were in progress, the registered membership was 386. This number does not include accompanying relatives. The membership was distributed by countries as follows: Argentine, 2; Belgium, 7; Canada, 67; Cuba, 1; Czechoslovakia, 3; Denmark, 3; France, 25; Georgia, 1; Great Britain, 39; Holland, 4; India, 2; Ireland, 3; Italy, 11; Mexico, 1; Norway, 5; Poland, 3; Portugal, 2; Rumania, 1; Russia, 5; Spain, 3; Sweden, 3; Switzerland, 4; Ukraine, 1; U.S.A., 189; Yugoslavia, 1.

The number of papers presented was very great—235 in all, exclusive of the lectures already mentioned. Of these papers, some, in the absence of the authors, could only be presented by title. On account of the desirability of affording the members an opportunity of seeing Niagara Falls, and also in view of the many entertainments so generously offered, the time available for the reading of so many papers was none too

g It was found necessary, on some of the days, h/e all the eight groups representing sections and ctions in operation simultaneously, and thus ers had to make an invidious choice between arious groups at which papers of rival interest ere being presented. In the circumstances, it was ult to suggest a remedy for this state of affairs lle than the expedient of cutting down the time nce for individual papers so far as to detract sly from their interest. The general maximum allowance for a paper was twenty minutes, but case of certain communications, which might be led as lectures to individual sections, this allow- was increased up to one hour. Such sectional es were: Prof. J. Pierpont: Non-Euclidean etry from a Non-Projective Standpoint on II.); Prof. V. Bjerknes: Solved and Un- Problems in Dynamical Meteorology (Section b)); Prof. J. B. Pomey: Sur les nouveaux eils multiplex de télégraphie (Section IV. Prof. G. Puppini: Principe de réciprocité dans sciences appliquées (Section IV. (a)); Sir es Parsons: Physics and Engineering (Section a)); Prof. J. G. Gray: Gyroscopic Stabilisers on IV.); General Charbonnier: Sur le balis- extérieur (Section IV. (b)); Prof. A. L. ey: Use of Mathematics in Economic, Social, ublic Statistics (Section V.).

e numbers of papers presented to the various ns were: Section I. (Algebra, Theory of Num- Analysis), 56 papers; Section II. (Geometry), apers; Section III. (a) (Mechanics, Mathe- al Physics), and III. (b) (Astronomy, Geo- cs), together, 55 papers; Section IV. (a) (Elec- l, Mechanical, Civil and Mining Engineering), IV. (b) (Aeronautics, Naval Architecture, Ballistics, Radiotelegraphy), together 47 papers; Section V. (Statistics, Actuarial Science, Economics), 24 papers; Section VI. (History, Philosophy, Didactics), 13 papers.

The classification of papers into the various sections, a matter always arbitrary to a certain degree, was left almost entirely to the judgment of the authors themselves, who would naturally seek the most sympathetic audience. It will be seen that, as usual, the Section on Analysis had more communications than any other, being closely followed by the combined Physics and Astronomy Section. Section IV., embracing the various branches of engineering science, was a new development for this Congress. Although the number of papers in Section V. was not large, yet the meetings of this section were very successful, and recognition is due to the activity of Mr. Robert Henderson, of the Equitable Life Assurance Company of New York, in helping to stimulate American interest in this section.

In order to increase the interest of the meetings and to facilitate discussion, the organising committee had abstracts of the papers printed and ready for distribution among the members on registration. These abstracts were supplied by the authors. This was a very successful measure so far as it went, but many authors failed to send in abstracts although asked to do so in the preliminary circular. If funds permitted at future congresses, it would be a good plan to urge upon authors more strongly the desirability of furnishing such abstracts for printing and distribution during the meeting.

The place of meeting of the Congress which is due to be held in 1928 is not yet fixed. It is to be hoped that the political restrictions on the membership of the congresses will be removed before that date.

Miners' Flame Safety Lamp Gauzes.[1]

ALTHOUGH a period of 109 years has elapsed since Sir Humphry Davy gave to the world e first wire-gauze safety lamp, the mesh of the ues in use to-day is identical with that adopted e original Davy lamp. In the near future, wever, it is highly probable, as a result of the uable researches conducted under the auspices of eliners' Lamp Committee, that safety lamp gauzes l have 400 apertures per square inch (20 mesh) ad of 784 apertures per square inch (28 mesh).

ese researches showed that two 20-mesh gauzes S.W.G. wire could be regarded as safe, and that type of gauze, by affording increased ventilation lamp fitted with it, materially increased the le power that could be obtained from it. Acting he advice of this Committee, the Secretary for ns arranged with the co-operation of leading manu- rers of flame safety lamps for comparative tests e carried out at the Mines Department Lamp ing Station of (1) lamp fitted with the present dard gauzes (28 mesh), and (2) similar lamps fitted t gauzes having 20 meshes to the linear inch. By direction of the Secretary of Mines, the Super- dent Testing Officer's report on these tests has been printed.

e tests carried out consisted in the main of hotometric tests; (2) tests in a still explosive osphere, and (3) gallery tests in a current of the explosive mixture of petroleum, ether, and air.

e photometric tests which were made by a sen disc photometer against a one candle-power dard pentane lamp yielded the following results:

Average Candle-power given by various Types of Flame Safety Lamps.

Type of Lamp.	Candle-power with 28 mesh Double Gauzes.	Candle-power with 20 mesh Double Gauzes.	Average Increase in Candle-power.
			Per cent.
Marsaut	0·62	0·82	32·3
Marsaut with short inner metal chimney	0·70	1·01	28·0
Marsaut deflector	0·71	0·85	19·7
Marsaut deflector with short metal chimney	0·77	0·94	22·1
Marsaut with inner metal chimney and inner glass	0·89	1·10	12·2
Bottom feed with bottom air admission ring	1·05	1·20	14·3
Air feed from middle ring to below the wick	1·80	1·85	3·0

From statistics published in the Final Report of the Miners' Lamp Committee it would appear that in the event of the new gauzes being adopted, approximately 402,000 Marsaut type lamps would obtain the benefit of an average increase of 32·3 per cent. in candle power, whilst 182,000 lamps of other types would benefit by an average increase of 16·1 per cent. in candle-power.

Although the Safety Tests were of a most severe character, none of the lamps submitted failed to pass the test satisfactorily, and Capt. Platt, the Superintending Testing Officer, is of the opinion that the factor of safety under test conditions is sufficiently great with the 20-mesh gauze.

[1] eport on Tests of Miners' Flame Safety Lamps fitted with Open Mesh us, carried out at the Mines Department Lamp Testing Station, kcals, by Capt. C. B. M. Platt. (London: H.M. Stationery Office.) 3d.

The British Dyestuffs Corporation.

TWO important pronouncements regarding the present position of the British Dyestuffs Corporation appeared in the press last week. In a written reply to a question put in the House of Commons by Mr. Graham White, the President of the Board of Trade, Mr. Sidney Webb, said: "The Board of the British Dyestuffs Corporation have been informed that the Government would feel compelled to exercise their power of veto with respect to an agreement with the Interssen-Gemeinschaft on the lines suggested."

In making this decision, the Government has taken the only course consonant with national welfare and with the best interests of the textile industries. The question of the agreement has never been specifically before the shareholders of the Corporation, but it has been for some time abundantly evident that the views and policy of the directors and of the financiers who hold large blocks of shares were opposed to the considered opinions of all the important industrial and scientific organisations concerned.

In view of the Government veto, other methods of dealing with the present unfortunate position of the British Dyestuffs Corporation must be necessarily explored, and definite alternative proposals are not lacking. In his recent address as chairman of the Colour Users Association, Mr. Sutcliffe Smith made proposals for the reconstruction both of the financial and management sides of the Corporation, and, speaking before the Society of Dyers and Colourists in Bradford on October 9, Dr. Herbert Levinstein, who has been engaged in dyestuff manufacture all his life and is also probably the largest individual shareholder in the British Dyestuffs Corporation, subjected the position of the Corporation to a critical examination.

According to the *Times*, October 10, Dr. Levinstein said: "Last April, at the annual meeting, the chairman stated that the board would resign if they were not encouraged to complete the agreement as outlined. The colour consumers, the customers of the company, through the chairman of their association, have definitely stated that they disapprove of the agreement, that they will prevent it if they can, and will welcome an entire reorganisation of the management. Further, the agreement, the headings of which have become known, is opposed by every one of the organised bodies in Great Britain representing pure and applied chemistry, including the Association of British Chemical Manufacturers. Thus it appears that the policy of the board and the constitution of the board are disapproved by the whole of the chemical world and by their customers, the colour-using interests. Out of much that is obscure this much is certain. The agreement has not been approved. The situation contemplated by the chairman and his colleagues has arisen. The board have not been encouraged to complete the arrangements with the I.G. in which they put their faith, and they will no doubt tender their resignations." At the annual meeting of the Corporation last April, several speakers, men of high standing in the City of London, who represented substantial financial interests in the company, supported both the board and the agreement. The public flotation of the Corporation was not a success, a large proportion of the shares remained, and apparently still remain, with the underwriters, and Dr. Levinstein viewed with concern this divergence of views between colour users and those who represented the underwriters.

The position is one of great gravity as regards the future of the British Dyestuffs Corporation. The problems imposed on the directors by inherent difficulties of the position have not been solved by the proposals, and it has been shown once again that the special conditions involved in chemical manufacture in general, and in dyestuff manufacture most particularly, cannot efficiently be dealt with by a board which bases its policy on financial, rather than technical requirements. The improbability of the success of any dyestuff concern managed on these lines was predicted by Lord Moulton and others, and strong but unavailing appeals were made in NATURE and elsewhere that the directorate should contain a strong technical element.

The solution of the present lamentable position appears to be a drastic reorganisation of the British Dyestuffs Corporation's finances and policy, coupled with an all-British, instead of a German-British agreement. It is stated that British firms outside the Corporation are at present supplying three or four times as much dyestuff to British consumers as does the Corporation, and are, in fact, its chief competitor.

WALTER M. GARDNER.

University and Educational Intelligence.

BIRMINGHAM.—The following appointments have been made: Mr. Robert H. Kinvig to be reader in geography; Mr. Launcelot P. Timmins to be lecturer and demonstrator in oil production in the Department of Oil Mining; and Mr. W. J. Shearer to be lecturer in coal mining and mine rescue work. Dr. Beatrice Webb has been appointed medical officer to the Women's Training Department in the place of Miss Olive Elgood Turner, who has resigned.

Under the title "Careers to which subjects may lead, and other information," the Faculty of Science has issued a booklet "for the guidance of those who intend to enter the Faculty of Science of the University, and for the information of Heads of Schools, Parents and Guardians concerned." This publication, for which there is already a considerable demand, sets forth the qualifications desirable in any one about to enter the Faculty of Science, great stress being laid on the necessity of a sound knowledge of English. Some knowledge of physics is regarded as essential in all subjects, and an acquaintance with German is strongly advised. An indication is given of the careers which are open to successful students in the various departments, and the pamphlet should be of great value in enabling intending undergraduates to decide upon the subjects to which they can most advantageously devote their time at the University.

BRISTOL.—An agricultural chemist is shortly to be appointed to assist in advisory work in the Bristol province under the advisory scheme of the Ministry of Agriculture. Particulars may be obtained from the Registrar of the University. Applications for the post should reach the Registrar not later than October 25.

CAMBRIDGE.—The new year finds the college busily occupied with the drafting and passing of statutes to meet the recommendations of the recent Royal Commission and the requirements of the Statutory Commissioners. So far the University has not been asked to devote much time and labour to the task of drafting statutes and ordinances, save for the new pension statutes, which will bring its future staff, and, so far as possible, its present staff, within the Federated Superannuation System for universities. It would, however, seem inevitable that when

the Commissioners come to grips with the detailed requirements of the Faculty Scheme, the provisional outlines of which have been already reported in these columns, the co-operation of the resident teachers must be sought. University and college officers alike look forward to a busy year, which will, in many matters, be of vital importance in the history and development of the University.

The department of the University which looks forward to immediate development is that of pathology owing to the generous endowment for a new laboratory by the Rockefeller Trustees and Mr. Ernest H. Gates. Building is also to be done for the Animal Diseases Institute and for an extension of the School of Agriculture. New college buildings at Jesus and Sidney Sussex Colleges will also soon be completed, the former being occupied this term. From all accounts the number of students is to remain at the same high level as in recent years, and the pressure on laboratories and on college accommodation is to remain very heavy.

Mr. T. M. Cherry and Mr. J. H. Quastel, research students, have been elected to fellowships at Trinity College.

LONDON.—The final report of the Royal Commission on University Education in London was dated March 25, 1913, and it is suggested that some modifications of its provisions may be desirable. The president of the Board of Education has therefore appointed a committee "to indicate what are the principal changes now most needed in the existing constitution of the University of London and on what basis a Statutory Commission should be set up to frame new statutes for the University." The committee is constituted as follows: Lord Ernle (chairman), Sir Robert Blair, Dr. H. L. Eason, Mr. H. B. Lees-Smith, Sir Henry Miers, Prof. A. F. Pollard, Sir Amherst Selby-Bigge, Bt., Miss K. Wallas, and Mr. S. H. Wood (secretary, to whom all communications should be addressed at the office of the Board of Education, King Charles Street, Whitehall, S.W.1.

At an extraordinary meeting of the Senate held on October 9 to consider a communication, dated September 15, 1924, from the president of the Board of Education with reference to the appointment of a Departmental Committee on matters connected with the University, the following resolution was unanimously carried: "That the president of the Board of Education be respectfully reminded that the Senate was not consulted as to the reference to the Haldane Commission, nor represented upon it, nor gave evidence before it; and that, having regard to the successful progress of the University since the report of that Commission, the Senate is of opinion that such changes in the organisation of the University as are necessary may be more readily effected by amendments promoted by the University than by a statutory revision of the University as constituted by the Act of 1898; but that the Senate will be prepared to furnish through its officers and appropriate Committees any information desired by the Departmental Committee, and trusts that the various bodies and interests represented on the Senate will receive a full opportunity of putting individually or collectively before the Departmental Committee their views on the matters under consideration."

The Semon lecture for the present year will be delivered at the Royal Society of Medicine, 1 Wimpole Street, W., at 5 o'clock, on Thursday, November 6, by Dr. D. Guisez, of Paris, who will speak (in French) on "Malignant Disease of the Gullet." A course of four lectures on "Enzymes" will be given by Prof. J. Mellanby on November 6, 13, 20, and 27 at St. Thomas's Hospital Medical School at 4.30 each day. No tickets will be required either for the Semon lecture or the course on "Enzymes."

ST. ANDREWS.—At a meeting of the Court held on September 7, it was unanimously resolved to appoint Mr. J. N. Wright, at present assistant in the department of logic in the University, to the lectureship in logic and psychology in University College, Dundee, and the United College, St. Andrews; which became vacant upon the appointment of Prof. Morrison to the chair of moral philosophy. Mr. Wright, who is a graduate of the University of Durham, has been assistant in the department of logic in the University since 1920.

At a meeting of the University Court on September 29, Dr. O. R. Howell was appointed lecturer in chemistry in University College, Dundee, in succession to Dr. J. S. W. Boyle, lately appointed headmaster at Prestonpans. The following nominations of assistants were approved: botany (St. Andrews), Miss C. I. Kean; chemistry (Dundee), Mr. C. A. Kerr; mathematics (Dundee), Miss Mary C. Simpson; chemistry (St. Andrews), Mr. G. J. Robertson. Mr. G. B. Steele was appointed lecturer in civil engineering and structural design, University College, Dundee.

It was intimated at the meeting that the arrangements are now complete for carrying on in Dundee a course of lectures during the coming session in railway geography, intended for the staffs of the railway companies, the lecturer being Mr. D. E. I. Innes.

The degree of Ph.D. has been conferred on Mr. G. J. Robertson for a thesis entitled "Investigations on Cellulose," and on Mr. R. S. Vaidyanathaswamy, of Madras Province, for a mathematical thesis entitled "Contributions to the Theory of Apolarity."

SHEFFIELD.—The following appointments have been made: Miss Alice Garnett, to be assistant lecturer in geography; and Dr. R. Platt and Dr. C. W. A. Lister, to be demonstrators in physiology.

ACTIVE efforts are being made to raise the sum of 20,000*l.* for necessary extensions of Queen's College, London. The chairman of the general committee is Lord Askwith, and a distinguished body of patrons is supporting the appeal. Donations amounting to 7000*l.* have already been received, and it is hoped that the remainder of the sum required will be forthcoming from old students of the College or benefactors interested in the higher education of women. The Duchess of York has graciously consented to visit the College on Saturday, November 1, and to receive purses collected for the extension fund. Queen's College was established in 1848 and incorporated by Royal Charter in 1853. It was the first college for women, and remains as independent to-day as it was when first constituted by F. D. Maurice, R. C. French, Charles Kingsley, Sterndale Bennett, D. T. Ansted, Edward Forbes, and other leaders in different departments of progressive thought. For some years the work of the College has been carried on without adequate accommodation or equipment, yet its record for scholarship and inspiring teaching is remarkably high. There should not be much difficulty in securing the relatively modest sum required to enable the College to maintain a worthy place among institutions for the higher education of women. Contributions to the appeal fund should be sent to the hon. treasurer, Sir James Williamson, or to Mrs. Allport, at the College, 47 Harley Street, London, W.1.

Early Science at the Royal Society.

October 19, 1664. Dr. Merret brought in his catalogue of trades, which was read and approved of; and it was ordered, that the amanuensis should fairly transcribe it against the next meeting, and that then it should lye exposed, at the time of the meeting of the society, for the several fellows to look it over, and to choose what trade they would give or procure the history of.—Mr. Hooke said he had observed, that upon the fall of the mercury wet weather followed.—Sir Paul Neile renewed his former motion of observing the figure of the sun at his rising and setting, both at Whitehall and Greenwich. Sir R. Moray was desired to observe it at Whitehall, and to recommend the observation of it at Greenwich to Mr. Marre.

1674. Mr. Hooke acquainted the council, that Sir Jonas Moore had been with him at Chelsea College, and made an overture of engaging a gardiner, a sufficient man, to take a lease of the house and land about it, and paying a yearly rent; allowing withal to the Society to make hortulan experiments there; as also to build an astronomical observatory, which latter Sir Jonas Moore would undertake to do at his own charges, to the value of an hundred and fifty or two hundred pounds.

October 21, 1669.—A Latin letter from Signor Malpighi was read acknowledging the favour of election, and in causing his discourse on the silk-worms to be printed.—Thomas Willisel the botanic traveller, employed by the society, brought in his collection of plants gathered in several parts of England and Scotland, together with some rare Scottish birds and fishes.—The lord bishop of Chester acquainted the society, that his Majesty had expressed a desire of having the measure of a degree of the earth determined, and expected the assistance of the society in it.

October 22, 1662. Dr. Merret mentioned, that live worms are sometimes found in the stomachs and guts of salmons. He was desired to make some observations in those and other fishes. This gave occasion of discoursing upon what is called equivocal generation.—Dr. Charlton brought in his papers, in which he had reduced birds into certain families, in Latin and English; which papers were ordered to be kept; and the doctor was desired, in conjunction with Dr. Merret, to reduce fishes into the like classes.

1668. There was presented from Mr. Hevelius his "Cometographia," wherein he takes particular notice of the society in his address to the reader.

October 24, 1666. It was moved that the materials for building, and the several sorts of earth for making brick and tile, might now be considered by the society; who were desired to think upon it against the next meeting.—A paper communicated by Sir Theodore de Vaux was read concerning several ways of making cheap and sweet fires of coal-balls wherein sea-coal is by the mixture of other combustible bodies both sweetened and multiplied.—Sir Robert Moray presented the society for the repository with some stag's tears.

1667. The method of transfusing blood into a man, as it was contrived by Dr. King was read and ordered to be registered.—It being moved, that the experiment might be made accordingly, as it had been done already in foreign parts, Sir George Ent suggested, that he thought it most advisable to try it upon some mad person in the hospital of Bethlem. This being seconded by divers other physicians of the society, Dr. Lower [and others] were desired to speak with the physician to Bethlem, about the execution of this trial.

Societies and Academies.

MANCHESTER.

Literary and Philosophical Society, October 7. Miss Laura **Start**: The significance of some Ib textile designs.—J. **Walton**: On the existence liverworts as fossils in the Carboniferous rocks England. Dr. Lucy Wills has described some sma dichotomously branched thalloid plants in shales Upper Coal Measure Age in Staffordshire and su gested that they might possibly be fragments of Bryophyte. Some clayey shale from the Middle Co Measures of the Denbighshire coal-field yielde thalloid plants of a similar type of organisation, som with rhizoids attached. In addition, two fragmen of a plant which cannot be other than a folios liverwort were isolated by treatment of the sam shale. This latter plant is distinctly dorsiventra There are two rows of leaves, one on each side of th somewhat stout axial part of the shoot. The membe of the two series alternate. On the under (or th upper ?) surface of the axial part are two rows c smaller leaf-like appendages, each in definite relatio to one of the larger leaves and lying close to it. Thu it is now clear that there were both thalloid an foliose forms of liverworts in existence in Carbon iferous times.

PARIS.

Academy of Sciences, September 15.—M. Emil Roux in the chair.—Henry **Le Chatelier**: Th viscosity of glass. A discussion of the experiment of E. Washburn and E. Shelton on the viscosities c soda lime glasses. These authors give their result in graphical form, but it is shown that the results c these measurements can be very exactly represente by the double exponential formula: Log (log η $= -Mt + P$, in which η is the viscosity, t the tem perature, and M and P constants. Exterpolatio to the annealing temperatures, 500° C. to 600° C. gives results not in agreement with earlier work and it is suggested that glass, like sulphur, exists i two allotropic states.—W. **Abbott**: The breaking u of the southern polar cap of Mars. A description o the changes in the shape and appearance of the pola cap between May and August 14 of this year.— L. **Dunoyer** and P. **Toulon**: The interpretation o the sheath phenomena in arc relays.—H. **Robert** P. **Vernotte**, and A. **Jeufroy**: The measurement o the heating of the brushes of electrical generators The advantages of using a thermocouple instead o the conventional mercury thermometer are demon strated: the differences are magnified when the size of the dynamo is reduced.—E. **Hultén**: The origin of the band spectrum of mercury. There is some evidence, not quite conclusive, that the bands are due to the formation of some compound of the metal with hydrogen. The bands are more intense when a current of hydrogen at low pressure (1 mm.) is passed through the tube, whilst a current of air has the opposite effect.—P. **Vaillant**: The conductivity of solid salts at high temperatures. The con ductivity of solid sodium chloride first increased, then fell sharply. At 150° C. there was a rapid increase to the highest temperature employed (420° C.). On reheating, the initial rise and fall were not repeated, but the increase from 150° C. was the same as on the first heating. Potassium sulphate and chloride behave similarly.—P. **Loisel**: The radioactivity of the granites from Guérat, near Bagnoles-de-l'Orne. Study of emilium. The study of the gases dissolved in the water of a certain number of springs in the Bagnoles-de-l'Orne region led the author to conclude

hese gases contained, in addition to the radium ...tion, a new emanation (period 22 minutes). ...e ranites, treated by the method of Strutt and ...gave a gas the curve of which differed from the ...teristic curve of the radium emanation.— ...ult and A. **Funke**: The alkylidene-dibenzoyl- ...ic esters.—A. **Němec** and K. **Kvapil**: The ...osition of forest soils. Analyses of soil layers ...erent depths in forests of epicea, oak, and pine, ...lata including acidity, organic matter, and ...en.—**Lesné** and **Vagliano**: The production of ... milk with antirachitic properties. The addi- ...f cod-liver oil to the food of a cow modifies ...mposition of the milk and butter. The butter ... in lecithine and the growth vitamin. The ...chitic factor present in the butter is not identical ...vitamin A.—G. **Mouriquand**, Paul **Michel**, and ...erheim: New researches on the sensibilisation ... guinea-pig to C-avitaminosis. After an attack ...perimental scurvy, the guinea-pig is more ...sive to a second attack. This condition is not ...rnent, and slowly disappears. It is not funda- ...ully a true sensibilisation, and is closely con- ...d with the long persistence of lesions only ...le of detection by histological methods.— ...arat and J. **Painlevé**: Constitution of the ...lasm of a glandular cell: the cell of the salivary ...s of the larva of the Chironome.—Auguste ...ère: The mechanism of anaphylactic shock. ... to the criticisms of M. Bordet, maintaining ... lequacy of the author's flocculation theory.

ROME.

Royal Academy of the Lincei, June 15.—V. Scialoja ... chair.—M. **La Rosa**: The ballistic principle and ... elocity of light, and recent investigations by ...iph Tomaschek.—A. **Piutti** and Pasquale **Bado- ...o** Action of light on solutions of certain organic ...bances in chloropicrin. Although chloropicrin is ...le in the dark, it undergoes decomposition when ...ed to light, and the products thus formed exert ... issolved compounds either a chlorinating, an ...ising, or a substituting action; in some instances ... itro group is reduced to the ammonium group, ... separates as chloride or oxalate.—Gaetano ...vreto: Tectonic conditions of the Circean Prom- ...ty [of the Apennines].—Francesco **Tricomi**: ...erical resolution of Fredholm's integral equations. ...a **Zanoni**: Extension of Hadamard's equation ... ...e functional derivatives of Green's function to ...scity.—Luigi **Amoroso**: Mathematical theory of ...nities.—Bruno **Finzi**: A noteworthy class of fluid ...ons.—Emilio **Adinolfi**: Hall's effect in bismuth ...te case of weak fields. In the case of bismuth, ... alue of Hall's coefficient varies linearly with the ...gth of the magnetic field and exponentially with ... emperature.—Vasco **Ronchi**: Study of optical ...sms by means of the biprism and Fresnel's ...rs.—Mario **Amadori**: Hydrated active tartaric ... At temperatures below about 5°, tartaric acid ...rates from aqueous solution in a monohydrated ..., which crystallises in blunt prisms belonging to ...hombic system and gradually changes to the ...ary anhydrous crystals at temperatures above ...ct 10°.—L. A. **Herrera**: Imitation of nervous ...cellular tissue by means of potassium hydroxide, ..., and alcohol.—C. **Mazzetti** and F. De **Carli**: ...tivity of boric anhydride in the solid state with ...llic oxides. The borates of various metals may ... obtained by heating the corresponding oxides with ... anhydride at temperatures below those at which ...respective mixtures undergo fusion.—G. R. **Levi** ... A. **Ferrari**: The crystalline lattices of the ...bohedral carbonates of divalent metals.—S. **Ranzi**: Increase of the surface and increase of the volume during the development of the otocysts of Bufo. In the development of these otocysts, the increase in the surface does not always proceed *pari passu* with the increase in the volume. At certain periods of the embryogenesis there is predominance of the former, expressed by demarcation of the parts and by slight wrinkling of the walls, whilst at other periods increase of the volume, indicated by disappearance of the demarcation and by a tendency of the organ to become spherical, assumes ascendancy. —G. **Fadda** and I. **Schiacchitano**: The significance of the polar groove in relation to that of the diameter of the fertilisation membrane.—M. **Topi**: Existence of various species of vine Phylloxera, and the susceptibility of American vines to Phylloxera. Like Arizona vines suffering from Phylloxera, infected roots of Italian vines seem unable to impart this disease to American vine varieties.—G. **Cotronei**: The phenomenon of contraction in relation to sexual maturity and to senescence in Petromyzon. Although these organisms persist sexually immature for several years, the senescent phase, expressed by a profound atrophy, occupies only about a month, during which period the animal is used up by the activity of the reproductive elements.—C. **Artom**: Variation in the radio-sensibility of the cellular elements in pecilothermic organisms. The results of Packard's recent work on the susceptibility of cells to radium emanations fully confirm the conclusion drawn by the author from his experiments on *Paludina vivipara*: that in cold-blooded organisms the radio-sensibility of the cellular elements varies considerably with the temperature and that such organisms therefore constitute excellent material for determining the exact relationship between temperature and cellular radio-sensibility.—C. **Verdozzi**: Modifications of certain internal secretory glands (suprarenal capsule, thyroid, ovary, spleen) during lactation.

SYDNEY.

Linnean Society of New South Wales, August 27.— Mr. J. J. Fletcher, vice-president, in the chair.— T. **Steel**: The nectar of flowers. Direct observation of the disappearance of nectar from protected flowers shows that, when not removed by birds or insects, this secretion is soon re-absorbed by the plant, apparently going to nourish the growing ovary. This may be the original purpose of nectar secretion in general. There are great differences between the densities of nectar as it occurs in flowers, and of honey in the comb. In the flowers examined the total sugar in the nectars varied between 9·05 and 41·20 per cent. Each species appears to have a fairly constant nectar density.—T. Harvey **Johnston**: An Australian caryophyllæid cestode. The paper describes the structure and relationships of the first caryophyllæid cestode to be described outside Europe, Asia, and North America, making the eighth species known in the family. A new genus is proposed to receive it. The parasite is noteworthy as being the first member of the family known to parasitise fish other than cyprinoids, its host being the jewfish, *Tandanus tandanus* Mitchell, a siluroid, from Queensland rivers.—J. R. **Malloch**: Notes on Australian Diptera. No. iv. Notes on the families Drosophilidæ and Chloropidæ, eight species being described as new in the former, and two genera and six species as new in the latter.—P. D. F. **Murray**: The motor nerve-endings of the limb muscles of the frog (*Rana temporaria*) and of the muscles of the pectoral fin of the dog-fish (*Squalus acanthias*). The nerve-endings were impregnated by the Bielschowsky method. Two kinds of motor nerve-endings are

described in the limb muscles of the frog, one coarse, one fine; the latter may be the sympathetic innervation. In connexion with the motor nerve-endings in the muscles of the pectoral fin of *Squalus acanthias*, at least two types of periterminal network are described, and another terminal organ in the sarcoplasm under the end-ring, which seems not to have been described hitherto.—J. M. **Petrie**: Studies in plant pigments. Part ii. The red pigment induced by insect injury in *Eucalyptus stricta*. Leaves of *Eucalyptus stricta* were found to be injured by a microscopic mite, and, as a result, great fasciation had taken place, and a bright red colour produced. The colouring matter of these red fasciated leaves was isolated and examined chemically. No trace of anthocyanin could be identified, but instead, the pigment was proved to be a catechol tannin red. It was obtained in red non-crystalline flakes, and soluble in alcohol and alkalies. The red pigment is probably one of the first anhydrides, or soluble phlobaphenes, of a catechol tannin.

Official Publications Received.

Proceedings of the Royal Society of Edinburgh, Session 1923-1924. Vol. 44, Part 2, No. 20: The Magnetic Quality of very Pure Nickel. By Ada M. Malcolm. Pp. 206-210. Diary of Societies.

SATURDAY, OCTOBER 18.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 4.—Sir Archibald E. Garrod: Harveian Oration.

PHYSIOLOGICAL SOCIETY (at Guy's Hospital), at 4.—E. D. Adrian: The Reflex Electric Response of Antagonistic Muscles.—Ff. Roberts: The Short-circuited Circulation.—J. Mellanby: The Action of Digestive Enzymes on the Red Cell.—J. F. Fulton: Alterations in the Size of the Electrical Responses of a Muscle Fibre produced by small Alterations in Tension.—D. T. Barry: Some Points in the Formation of a V-wave in the Venous Pulse.—R. J. S. McDowall and B. L. Worsnop: The Effect of Histamine on the Aorta of the Living Animal.—J. Barcroft, C. A. Murray, and I. Sands: The Effect of Splenectomy on Coal-gas Poisoning.—I. Sands: Self-oxidation in the Blood of the Earthworm.—J. M. H. Campbell, G. O. Mitchell, M. S. Pembrey, and A. T. W. Powell: The Effect of Muscular Work upon Digestion.—M. S. Pembrey: The Weight of the Heart in Different Conditions.—A. N. Drury: The Spread of the Excitatory Process in Auricular Muscle subjected to Pressure.—A. N. Drury and E. C. Andrus: The Influence of Hydrogen Ion Concentration on the Mammalian Auricle.—Demonstrations.

BIOCHEMICAL SOCIETY (at Cambridge).

MONDAY, OCTOBER 20.

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (at Queen's Hotel, Leeds), at 7.—Annual General Meeting.

JUNIOR INSTITUTION OF ENGINEERS (North-western Section) (at 16 St. Mary's Parsonage, Manchester), at 7.15.—G. E. Blyth: Powdered Fuel.

CHEMICAL INDUSTRY CLUB (at 2 Whitehall Court, S.W.), at 8.

TUESDAY, OCTOBER 21.

ROYAL HORTICULTURAL SOCIETY, at 4.—Lecture.

ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting of Fellows.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Secretary: Report on the Additions to the Society's Menagerie during the months of June, July, August, and September.—Prof. H. M. Lefroy: Exhibition of lantern-slides illustrating the life-history and habits of the Death-Watch Beetle.—R. I. Pocock: The External Characters of the South American Edentates.—Rev. Dr. F. J. Wyeth: The Development and Neuromery of the Fore-brain in Sphenodon.—H. C. Abraham: Some Mygalomorph Spiders from the Malay Peninsula.—Joan B. Procter: Unrecorded Characters seen in Living Snakes and Description of a new Tree-Frog.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—Sir James Kemnal: Tendencies in Steam Generation.

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub-Centre the College, Loughborough), at 6.45.—F. W. Nicholls: Realisa Heat Units in Steam and Electric Power Plant.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—H. A. T Old English Country Homes.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at Cov at 7.15.—Dr. W. R. Ormandy: Research (Presidential Address).

INSTITUTE OF CHEMISTRY AND SOCIETY OF CHEMICAL INDUSTRY (Edi and East of Scotland Section) (at 36 York Place, Edinburgh).—W Woolcock: Opening Address.

WEDNESDAY, OCTOBER 22.

FARADAY SOCIETY, GEOLOGICAL SOCIETY, AND MINERALOGICAL S (at Geological Society), at 3.—Dr. J. S. Flett: Introductory Add Dr. G. W. Tyrrell: Review of Recent Work on the Origin and Diffe tion of Igneous Rocks.—Prof. W. E. S. Turner: The Physical Pro of Silicate Glasses.—A. F. Hallimond: The Formation of Eutect Similar Structures in Silica Melts.—Prof. J. W. Gregory: Ma Ore Deposits.—Dr. J. W. Evans: Proposed Researches in the Che and Physics of Igneous Magmas Rocks.—Prof. C. H. Desch Theory of Crystallisation in Rock Magmas.—Dr. A. Scott: Equili of Igneous Rocks and the Influence of Certain Factors on it.—P Niggli: Homogeneous Equilibria in Magmatic Melts and their B on the Processes of Igneous Rock Formation.—Dr. W. A. Richa Some Ultimate Problems in Petrogenesis.

INSTITUTION OF ENGINEERING INSPECTION (at Royal Society of A 5.—A. Hamilton: Crankless Engines.

INSTITUTION OF AUTOMOBILE ENGINEERS (North of England Cent 244 Deansgate, Manchester), at 6.30.—Dr. W. R. Ormandy: Re (Presidential Address).

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Hotel, Birmingham), at 7.—W. Lawson: Chairman's Address.

ROYAL MICROSCOPICAL SOCIETY (Industrial Applications Sectic 7.30.—J. E. Barnard: The Elementary Principles of Microsc Illumination—(1) Transmitted Light.—Dr. R. H. Greaves: saturated Solid Solutions.—H. Wrighton: New Photo-microg Apparatus for all purposes.

THURSDAY, OCTOBER 23.

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Grou Engineers' Club, Coventry Street, W.C.), at 5.—H. Griffiths: C lisation.—T. V. Barker: The Development and Formation of Cry

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—W. B. Woodhous augural Address.

INSTITUTION OF AUTOMOBILE ENGINEERS (Luton Centre) (at Luton), G. L. Ensor: Positive Valve Control.

C.B.C. SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND R PROGRESS (at Essex Hall, Essex Street, W.C.), at 8.—Dr. Marie S The Present Position of the Birth Control Movement (Presid Address).

INSTITUTION OF WELDING ENGINEERS (at Engineers' Club, Co Street, W.), at 8.—E. A. Atkins: Steel Wire: its Manufa Properties, and Uses for Welding and other Purposes.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Ch Street, W.), at 8.15.—Sir Malcolm Watson: Observations on M Control with special reference to the Assam Tea Gardens.

FRIDAY, OCTOBER 24.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science Technology), at 5.—D. Gunnaiya and G. Subrahmaniam, with D stration by D. J. Blaikley: Underblown Pipes.—W. Mandell J. West: The Temperature Gradient in Gases at Various Pressu J. F. S. Ross: Vectorial Dimensions.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur K Anatomy and Malformations of the Heart (2). Specimens illusti the common kinds of Congenital Malformation.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. E. Saun "Close-ups" at the Zoo.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—F. F. Evans: Pow Fuel.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUI (Middlesbrough Branch) (at Cleveland Institution), at 7.30. McGovern: Address.

PUBLIC LECTURES.

SATURDAY, OCTOBER 18.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. Dewey: Cornish Sc and its Causes.

MONDAY, OCTOBER 20.

KING'S COLLEGE, at 5.30.—Prof. E. W. Scripture: Prose and analysed by the Newer Methods.

TUESDAY, OCTOBER 21.

BEDFORD COLLEGE FOR WOMEN, at 5.15.—Prof. H. Piéron: La Dou au point de vue des fonctions affectives et perceptives (in Fren (Succeeding Lectures on October 22, 24.)

GRESHAM COLLEGE, at 6.—W. H. Wagstaff: Geometry (Gresham Lect (Succeeding Lectures on October 22, 23, 24.)

SATURDAY, OCTOBER 25.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—F. Balfour-Browne: Life amongst Insects—(1) Ants, Bees, and Wasps.

Popularisation and Sensationalism.

THERE can be no doubt that at the present day the question of the popularisation of science has acquired new interest and importance; it has been for some time an increasingly recurrent theme in our columns. The times seem in many ways to offer a new opportunity; great things—very great things—have been occurring in science, and in view of them we realise more than ever the grievousness of our intellectual condition, a condition where not only the multitude lie in ignorance but also where those who pass as the best informed have been left by their higher education without eyes to see, or ears to hear, the greatest happenings in the progress of human knowledge.

There is, we must gladly admit, evidence of an awakening, of some growing sense of shame, and of a genuine and widespread desire to learn. Among those who direct the newspaper press, which, we are assured, reflects rather than leads public opinion, there are signs of an increasing disposition to bring science into the daily diet they provide. In a certain number of cases, science has become what is technically known as a "feature"—like the music and art columns; and it has even shown the possibility of providing at times a "scoop." Broadcasting, again, is opening up new channels of communication which, if properly used, may be of unequalled importance in creating among the multitude an intelligent interest in science.

It seems to us very important that at this juncture, men of science should be alert to seize their opportunities and that they should respond in every legitimate way to the growing demand. They should bend themselves to the task of translating science to the public and of giving all the knowledge that is possible of its meaning, its methods, and its march. We need scarcely add that the task is one of very great difficulty. The public must have what the public wants: if it desires to be informed, it demands before that to be interested. Its own point of view, its primitive state of knowledge in all that relates to science, must be carefully regarded. Liveliness of exposition is as necessary as lucidity. The thing can be done—it is well worth doing; and though it seems at present there are not many, we believe that there might, by taking thought, be many more who know exactly how to do it.

There is no doubt that many men of science shrink under the demand for popularisation, not only because it would divert them from what seems more serious work, but also because it threatens a loss of self-respect. We can all understand and sympathise with their apprehension, and it is only fair to say that to-day the position is becoming more difficult. The public

expectations of new marvels from science have been greatly stimulated; science gives a new promise of material for leaded type and heavy headlines, it may even reach the evening "contents" bill; camera-men are in waiting at every corner.

It is easy to understand the reluctance, which all this inspires in modest men, to venture on the territory of press publicity, and to incur the risk of inclusion with charlatans whose "amazing" discoveries still find so ready an acceptance there. We believe, however, that the risk is worth while and that with reasonable care the dangers can be avoided. Vigilance is, however, becoming increasingly necessary, and it is of the first importance that public opinion within the scientific world should express itself plainly when this vigilance is neglected.

It is with this sense of obligation that we feel compelled to express very great regret that, in one of the younger universities, the dignity of science should recently have been allowed to undergo what seems to us to be a very serious violation. We shall not attempt to enter into details, nor do we desire to particularise individuals. The essential fact is that a want of vigilance has led to an exhibition of vulgar sensationalism which, as we are well assured by the remonstrances that have reached us, is regarded by the reputable scientific world as being in the highest degree deplorable. We make no attempt to apportion blame; we are concerned only to enter a strong protest. It is possible that what has happened may act as a temptation to a few of the less thoughtful to the empty glories of the limelight. In so far as that is the case, it will, we trust, stir responsible people to the exercise of restraint. We do not think the chief apprehension lies in that direction. We fear rather that what has happened may prove to have given a serious set-back to the efforts, which have recently been showing more success, to induce our men of science to help in a wholesome alliance with the Fourth Estate in what, properly regarded, has the sanctity, and should have the sobriety, of a missionary effort of enlightenment. We can only hope that what has recently happened will leave behind nothing but a salutary warning.

There is at the present time great restlessness in the world; old landmarks and fixed points, and even rules of life, seem to have disappeared, and we are in the turmoil of readjustments on the grand scale. Amid the grave anxieties of this condition we have a temporary excitement breaking out here and there in all sorts of morbid forms. By coincidence we have in the world of science a corresponding stir of readjustments; let us see to it that we at least are not invaded by the discordant spirit of jazz.

The Human Factor in Coal Mining.

ON October 2 the Institution of Mining Engine held its annual meeting, at which Prof. J. Haldane was inducted into the presidential chair gave his presidential address: The occasion sufficiently unusual to merit special comment. It not an ordinary occurrence for the president of engineering institution to be a professor of physiolo but Prof. Haldane is no ordinary physiologist. He practically devoted his life to a study of the phys logical problems which the miner's occupation preser and to the discovery of how the miner's health a safety of life and limb are affected by the incidence accidents of his occupation, and how the ill-effects these can be guarded against. It is not too much say that it is to Prof. Haldane's studies that thousa of coal miners in Great Britain owe their lives and hea to-day, and that he has played a leading part in battle against the dangers of the industry which min engineers are waging with such conspicuous success t coal mining in Great Britain is safer than in any ot country in the world.

As might well be expected, Prof. Haldane's pr dential address had in it nothing at all technical; was essentially humanistic and laid stress upon t most important of all factors in any engineer industry, namely, the human element. He poin out that one of the most striking characteristics mining men is the deep and sincere feeling of comra ship that unites all classes amongst those actua engaged in mining work; or, as he put it: "I have of been present at a colliery during some time of trou or danger; and it was this comradeship, from high to lowest, that impressed me most. But whether not unusual trouble is present, one seems to meet co radeship as one enters the colliery premises or st into the cage." He points out that it is this readin with which miners "will give loyal and efficient servi will face any danger, will forgive imagined or r mistakes, and will take the rough with the smooth, t bad times with the good," that makes the miner ins upon his right to be treated as a man and not as machine; and Prof. Haldane expresses his strong vi that this feeling is really at the bottom of the so-call industrial unrest amongst miners. As he puts i "Neither high wages, high dividends, nor welfare schem will satisfy them in this respect, but only discerning a sympathetic treatment, the treatment of comradesh in a common enterprise—such comradeship as existed and between all ranks during the War, or such comrad ship as is taught in the Gospels."

Prof. Haldane makes clear that his experience h taught him that the mining engineer and mine manage

unconsciously perhaps, but nevertheless quite sincerely, to his attitude on the part of their men, and that they will sympathise with it and endeavour to give it every opportunity for expression within the limits which they find possible, having regard to the safety and well-being of the men themselves. In this sense a coal mine "is the outcome of human comradeship, which must in its own way, and of its own free will, the tools provided by physical and economic knowledge."

Throughout his address, Prof. Haldane shows clearly that he thoroughly appreciates the existence of the feelings of true cordiality, regard, and esteem which employers and employed in the coal-mining industry really entertain for each other, but which as a rule are not evident to those outside the industry, whereas the public at large, seeing only the surface of things, may well be inclined to disbelieve in their existence. Those engaged in the industry know well enough, for example, that during the recent long-drawn-out disputes, colliery owners and managers actually assisted from their funds the strikers of their own pits to tide over that period of hardship, but the general public never hears a word of such kindly actions. Constantly during the recent disputes one heard the opinion expressed by both sides in colliery districts that, if only the busybodies at headquarters would leave them alone, they could settle their own differences readily and amicably.

Prof. Haldane is one of the few who has rightly gauged the feelings of the average colliery manager and coal miner for each other, and he lays stress, as its importance deserves, upon this phase of the relations between masters and men, though he at the same time shows that coal mining must, in the interests of the nation itself, necessarily be so carried on as to be commercially remunerative to all concerned therein, and that the responsibility for seeing that the industry is thus able to pay its way rests primarily on the mining engineer. In Prof. Haldane's own words: "When we realise the actual responsibility to their fellow-countrymen of those whose duty it is to care for the financial soundness of the operations involved in British colliery undertakings, we see at once how great that responsibility is, and how important it is that sufficiently far-seeing men should bear it, and should not be suffered to be interfered with by ignorant persons, who are commonly officious in direct proportion to their ignorance."

Prof. Haldane's address is, as we have said, unique in the occasion of its delivery. It is also an outstanding example of the fact, too rarely recognised, that the scientific worker is better able than most men to see the spiritual side of human endeavour, and that no man can be a true physiologist without having at the same time a profound insight into the problems of psychology.

A Veteran's View of Modern Physics.

Atoms and Rays: an Introduction to Modern Views on Atomic Structure and Radiation. By Sir Oliver Lodge. Pp. 208. (London: Ernest Benn, Ltd., 1924.) 21*s.* net.

THE writing of a popular account of recent advances in any branch of science calls for many qualities if it is to be successful. The author must, in the first place, be able to interest and hold the reader without recourse to sensationalism, a truism which, like many other truisms, is often overlooked. He must be the master of clear and concise English, and remember that many words which have a special and defined significance for the expert have also a general meaning which is much more vague. He must have sufficient critical faculty to be able to select for emphasis the points which are really fundamental, and sufficient adaptability to feel when detail must be sacrificed for the sake of vividness. Above all, he should be able to make the reader see in the researches which he describes an example of the power and beauty of the true scientific method, as contrasted with the inspired guesswork to which the ordinary reader is apt to attribute the advances of science.

Sir Oliver Lodge possesses all these virtues, and, in addition, his own distinguished career as an investigator has left in him an informed enthusiasm which he is well able to communicate. He is a veteran who sees in the modern campaigns against the unknown a repetition, governed by the same general rules of war, of those earlier ones in which he was a leader, and he speaks with the authority of one who knows the conditions of the conflict, as against those who, having never seen the battle raging, attempt to develop an account of the hostilities from the dry despatches. Nearly twenty years ago he gave us, in his "Electrons," the best general account of the state of the electron theory at that time. Towards the end of that book he mentioned various theories of atomic constitution, and spoke of the "exaggerated uncertainty" of the position with special reference to Sir J. J. Thomson's contention that the atom of hydrogen contained only one electron. He also had something to say of the difficulties in the way of explaining line spectra. To-day he has to tell how the advances of the last fourteen years or so have brought clearness into the subject of the structure of the atom, of the quantum theory, of how Bohr's application of it has gone far to found a reasonable theory of spectra, and, in general, of the present state of the electrical theory of matter and the associated radiation problems. He appeals to a wider audience than he did in the earlier book, for very little general knowledge of physics is now assumed in the reader,

and such mathematical treatment as there is requires for its comprehension but an elementary knowledge of algebra.

The book does not present a strictly consecutive scheme, for Sir Oliver holds that, in the words of his preface, "it is only by treating a subject from many points of view, and by frequent repetition, that it gets any hold on the general mind. Effective exposition cannot be done crisply and compactly." Accordingly, in the first few chapters we find the electron, the nucleus atom, some of the fundamental facts of radioactivity, and other features of modern physics approached in different places from different points of view, a few facts and aphorisms being set down each time a particular problem presents itself. In this way the reader is gradually familiarised with the chief experimental facts and the leading speculations based on them, although, perhaps, a clearer distinction between the two might occasionally be made. We then come to the quantum theory, illustrated by simple examples from everyday life. "One cannot gain half a trick at whist." The analogy used a little later is not so good: we are asked to consider an assemblage of tuning-forks, each with a small pellet suspended so as to touch the prong. When a note of given frequency is sounded the forks of that frequency, and of that frequency only, will throw off the pellets. This is true, but it fails to represent the chief feature of the quantum theory, namely, that the energy with which the electron is flung off is, in cases governed by quantum laws, dependent on the frequency of the radiation, but not on its intensity. This is, of course, pointed out by Sir Oliver elsewhere, but the analogy is a poor one to have introduced.

A brief account of optical and X-ray spectra, followed by a resumed consideration of the nucleus atom, leads into an account of Bohr's theory of the hydrogen atom, to which a large part of the book is devoted. Sir Oliver has set out to give, in the most elementary form, the mathematics of Bohr's explanation of the simplest line spectra, and here he has been most successful. He considers in detail the problem of the simple circular orbit, and carries out the whole of the calculations by degrees over several pages, always explaining the dynamical principles as they arise in the most comprehensible way.

The treatment of heavy atoms is, necessarily, very slight. The physicist will be somewhat surprised at the sense in which the author has used the word *ionisation*, for by it he indicates the removal of an innermost, or K, electron, instead of, as is usually implied, an outer electron. For example, he says, "Even moderately heavy atoms cannot be ionised or dissociated by visible illumination, but can be disturbed by X-ray frequencies: the frequency needed to ionise an oxygen atom, for instance, should be si four times that which is sufficient to ionise hydrog It is a pity that the term *ionisation potential*, w already has a perfectly definite meaning, shoul thus reapplied to characterise a quite different q tity, while the accepted meaning of the term, w is of such importance for spectral theory, and, m over, is capable of simple exposition, is altoge neglected.

One of the questions most frequently asked by interested layman is, to put it abruptly, whether ether exists or no. The orthodox physicist of to- would, we take it, after trying to avoid the quest reply that the ether as a substance ceased to exist to be a good working hypothesis, if the expressio preferred) when the theory of relativity bec established: that we cannot speak of determin points in the ether, or measure a velocity relative t or, in short, endow it with ordinary mechanical perties. On the other hand, there is no objectio calling empty space, in which an electromagnetic exists, the ether, but to those accustomed to the substantial ether, this is much like calling a sp table without any food a meal—they ask for bread, we pass an empty plate, and tell them that they call its contents what they like. Sir Oliver wil course, have none of this; he is for the good old e with mechanical properties—*et plutôt deux fois qu' et plutôt trois que deux*. He has many interes speculations which involve its existence as a fluid suggests that it may have a structure, a textur vortices reminiscent of Descartes, and that propul may one day be achieved by a sort of reaction on massive ether. For the professional physicist, realises the spirit in which they are put forward, t suggestions and analogous speculations are ful interest, but it would have been well to warn the reader, to whose need the book is, in general splendidly adapted, of some of the difficulties in way of a substantial ether.

Again, there are certain calculations which ass that the electronic mass is unaffected by high spe calculations put forward because they lead to sugg ive coincidences. No one knows better than Sir Ol that the mass of the electron is not, in fact, constan indeed, he has clearly expounded this elsewhere— his lay reader will scarcely know what to make of th calculations. These are examples of our only gen criticism of the book, namely, that, for the ordin reader, there is too little separation of what is w established from what is fanciful speculation. T physicist will follow with delight Sir Oliver in confident, independent, and characteristically fearl excursions among the more ticklish problems of to-d

the less experienced may well wonder occasionally re he is.

hen Sir Oliver rises to speak at a scientific meeting, who know him rouse themselves from their reflec-s, or apathy, and prepare to hear some simple hs which have, perhaps, been overlooked, wittily exquisitely expressed. This book has much of the lity of his speeches: it is personal, persuasive, and sting, conceived in a broad spirit, and full of husiasm for progress made in the past, and the sibilities of the future. "The processes of Nature uld be enjoyable, even though the enjoyment is riously acquired." This sentence of his might serve motto for a volume that is characteristic of the hor, to have said which is to commend the book to ery discerning and comprehensive circle of readers.

E. N. DA C. A.

The Technique of Contraception.

Contraception (Birth Control), its Theory, History, and Practice: a Manual for the Medical and Legal Professions. By Dr. Marie Carmichael Stopes. Pp. xxiii+418+4 plates. (London: J. Bale, Sons and Danielsson, Ltd., 1923.) 12*s.* 6*d.* net.

DR. MARIE STOPES has written a very good book on birth control. Not the least of its merits is a simple directness which marks sincerity and contrasts pleasantly with the sentimental sloppiness which nauseates in many publications on the same subject. She relies on evidence, and marshals it in a clear, readable way. Given her point of view, we may differ from her on minor matters, but on the whole she compels agreement.

One cannot have one's cake and eat it too. Living things tend to multiply so fast that continuous high birth-rates and low death-rates are incompatible. High rates may coexist for ages, so may low rates; but never for long a high rate of one sort with a low rate of the other. In the end, a rapid increase of population implies a massacre of youth. On the other hand, many deaths and few births imply extinction of the race. Now and then, for limited periods and under special conditions, the demand for human beings may equal and even exceed the supply; but, as a rule, and always in the long run, the reverse is the case. Optimists tell us that Nature will provide for her children. She does—by means of war, or famine, or disease, or total hardship, or two or more of these combined. It is conceivable that the earth has resources which would maintain its present human population, multiplied a hundred- or a thousand-fold. But here we have only an ugly dream. Even if the earth, its romance and beauty gone, gradually became a great market-garden under intensive culture, its resources could not be made available fast enough. Demand creates supply; but the latter lags.

The struggle for space and existence is perhaps severest among such primitive savages as live on wild produce, which is usually scanty. Each tribe draws its subsistence from a wide area, within which it murders trespassers, and beyond which it seeks to exterminate neighbours. Contraception is known and practiced, or failing it abortion; or failing the latter, infanticide and neglect of the weak and aged. The taming of wild animals and plants increased production; and in time and for a time the labour of a robust individual gave subsistence for more than himself and his family. Thereupon wars of conquest displaced those of extermination. The strong sought not so much land and elbow-room as slaves, subjects, and tributaries. So men drew into larger aggregates. Civilisation dawned. Commerce became important. Means of communication improved. The deficiencies of one area began to be supplied from the superabundance of others. Finally, men turned more and more from agriculture to the manufacture of things which could be exchanged for food and other articles of use or luxury. During recent centuries this has been especially the case in England, where the great majority of the population is now urban.

For an epoch all went, or seemed to go, well with the British. Not only did they multiply, but wealth also bestowed power to bring food and other raw material from overseas. Presently, however, capital found insufficient opportunities for investment at home and was exported for the development of other lands. The latter soon began to manufacture and sell much they had bought in Britain, and even to export their wealth for more development elsewhere. This process cannot continue for ever. Emigration, which deprives us of some of our best human material, is almost negligible as a remedy. Apart from war, famine, and the like, no means, save contraception, of fleeing from the wrath to come can be thought of. Lacking it, the old savage wars for elbow-room must recur. Germany's struggle was nothing other. The mills of God grind slowly but they grind exceeding small.

Another line of reasoning is more decisive because more obvious. Contraception, whether right or wrong, has come to stay. In growing numbers men and women practise it in secret, and not all the king's horses and all the king's men can prevent them. In this connexion it is remarkable that the clergy, who in theory are the most determined opponents of contraception, have now the lowest, or almost the lowest, birth-rate in the kingdom. France and the United States have passed futile laws against it. During recent years the latter

country seems indeed to have developed a perfect genius for enacting edicts which cannot be enforced.

Dr. Stopes's book contains an introduction by the late Sir William Bayliss, and introductory notes by Sir James Barr and other medical people. Sir William Bayliss questions whether, as Dr. Stopes supposes, the seminal fluid contains hormones which, even in the absence of conception, are absorbed by, and are of value to, the female. The supposition is difficult to test, and Sir William's doubts will be echoed by many readers. The only experimental evidence is that furnished by John Hunter. "The semen would appear, both to smell and taste, to be a mawkish kind of substance; but when held some time in the mouth it produces a warmth similar to spices, which lasts some time." Evidently John Hunter was an intrepid experimenter! Of more than doubtful validity, too, is Dr. Stopes's belief (p. 139) "that in the fully excited uterus the cervix may spontaneously open and interlock with the glans penis." The cervix of the unimpregnated uterus is tough and gristly and its canal is many times too small for the glans.

But these and other speculations are of minor importance. The principal value of the volume lies in a careful and exhaustive discussion of the methods and technique of contraception—ancient and modern, savage and civilised, ranging from major surgical operations to simple and easily manipulated devices. Dr. Stopes's experience, gathered mainly from fertile but overburdened working women, mere drudges, alive but strangers to liberty and happiness, is so extensive that her opinions must necessarily carry weight. She condemns, except in special cases, all measures undertaken by the male, and advises in particular the use of a light rubber, dome-shaped, cervical cap. Of great value also is her history of the struggle to convey contraceptive knowledge to the public. Some such book as this had to be written, and this is very well written.

G. ARCHDALL REID.

The Sense-Organs of Animals.

Allgemeine Zoologie und Abstammungslehre. Von Prof. Dr. Ludwig Plate. Zweiter Teil: Die Sinnesorgane der Tiere. Pp. ix+806. (Jena: Gustav Fischer, 1924.) 22 gold marks.

THIS imposing and beautifully illustrated volume of about 800 pages forms an admirable text-book upon the sense-organs of animals. Its author is well known as successor of Haeckel and Director of the Phyletic Museum at Jena, as one of the most trustworthy of German writers on the philosophy of evolution, and as the author of highly important morphological researches, such as those upon the primitive gasteropods. Prof. Plate is primarily a morphologi yet he clearly recognises that evolutionary theo although its record is necessarily morphological, mu if it is to be fruitful, remain in close touch with phys logy. Indeed, his book is a good example of what t ideal text-books of general zoology in the future will in its happy combination of anatomy and physiolog

The volume contains a vast mass of detailed inform tion regarding the sense-organs, but it is no mere aggr gation of detail. On the contrary, the facts are w marshalled and fitted into an evolutionary framewo that makes the volume, large as it is, most interesti reading. It will prove of great use to the advanc student and also to those who have to lecture to a vanced students. Its perusal will prove illuminati alike to the narrow zootomist and the narrow physi logist. The latter, perhaps, accustomed to think sense-organs entirely in terms of those that happen exist in man, will have his outlook broadened l learning such facts as that within the group of insec alone, auditory organs have evolved independently i at least eight different methods out of the primiti sensory cells.

The volume is divided into fifteen chapters, deali respectively with general introductory matter, tacti and other skin sense-organs, lateral line organs, grav tational sense-organs, auditory organs of Invertebrate auditory organs of Vertebrates, temperature organ organs of smell and taste, physiological effects of ligh eyes of Invertebrates, general review of these, colou perception, eyes of Vertebrates, pineal organs, an general principles of the evolution of sense-organs.

The introductory chapter deals with basic matte such as the classification of sense-organs, the variou types of cell, sensory and accessory, which enter into th composition of sense-organs, and the various arrange ments for receiving and transmitting the sensor stimulus. The following chapters, constituting th main part of the volume, deal with the various sensor apparatuses in detail. The mass of information is fa too great for detailed notice in a short review; eac chapter constitutes an excellent survey of its particula subject-matter. A particularly interesting one is tha dealing with the auditory organs of terrestrial inverte brates. Thus about 25 pages are devoted to these organ as they occur in insects. The structural arrangement of chordotonal organs are first described, their functio being regarded as that of the detection of simple vibra tions. The various types of auditory organs are re garded as evolutionary developments from chordotona organs, the original function of perceiving simple vibra tions, possibly in correlation with control of win movements, having become specialised in the directio of appreciating sound. Such organs are seen in th

ranic organs present in cicadas, crickets, grass-
pers, and many sound-producing Lepidoptera, the
x, in each of these types of insect presenting
aracteristic peculiarities in detail which suggest that
e have evolved independently from the ancestral
hordotonal organ. Ignoring such differences in detail,
he tympanic organ consists of a piece of body-wall so
ined out as to form a delicate vibratile membrane
parating the outer air from an internal air-filled cavity
ormed by the dilatation of a tracheal trunk, and having
n nation to it peculiar sensory cells of the same type
s those seen in the chordotonal organs.

The succeeding chapter gives an interesting account
of the vertebrate type of auditory organ. The author
follows the fashionable practice of using the word
tal cyst rather than otocyst. This practice is, on the
whole, to be regretted. Either name is no doubt in
itself beyond criticism, but otocyst has an important
practical advantage in teaching, inasmuch as it brings
the less familiar type of organ and function into
relation with the more familiar instead of conversely.
It is also perhaps to be regretted that the author has
not simply ignored the sterile morphological contro-
versy regarding the homologies of the malleus and
incus of mammals. Morphologists of the future will
undoubtedly marvel at the greatness of the faith of
those who have regarded the developmental pheno-
mena exhibited by malleus and incus in the embryo,
and the palæontological facts which have been inter-
preted in accordance with them, as being of weight
sufficient to overcome the physiological improbability
of (1) new skeletal elements becoming intercalated in
a structure which must have been freely movable
throughout its functional history, and (2) the articula-
tion between jaw and skull being replaced by another
one without break of functional continuity. Apart
from such matters of opinion, the chapter gives an
excellent account of the vertebrate otocyst and its
variations, illustrated by a wealth of admirable figures,
among which we are glad to notice Gray's beautiful
photograph of the otocyst of Echidna.

In a work on the sense-organs, some of the most
interesting chapters are naturally those which deal with
sight. In this volume they occupy about half of the
whole. A general discussion is first given of the relations
of light to living processes. While the work of Loeb is
fully appreciated, Plate is more cautious than many in
following this author, and he does not forget to mention
Szmanski's interesting experiments on cockroaches,
which he succeeded in teaching them to avoid dark
corners by associating with darkness the idea of electric
shocks! The detailed description of the various types
of eye met with in the invertebrata occupies about 170
pages; it will be of the greatest utility to advanced
students desiring to have a comprehensive grasp of
eye-structure in all its varieties. A good chapter on the
eyes of vertebrates is followed by a short discussion of
evolutionary principles in relation to the sense-organs.

The book is admirably got up; it is well illustrated,
many of the best illustrations being original; it should
find a place in the library of every university depart-
ment of zoology or physiology. J. GRAHAM KERR.

Pyramid and Prophecy.

The Great Pyramid, its Divine Message: an Original Co-ordination of Historical Documents and Archæological Evidences. By D. Davidson and H. Aldersmith. Vol. 1: Pyramid Records; a Narrative of new Discoveries concerning Civilisations and Origins. Pp. xxvii + 568 (70 plates). (London: Williams and Norgate, Ltd., 1924.) 25*s.* net.

THIS elaborate work is one of the assertionist class which has spread in recent years. The pyramid theories open with many pages on the reflecting surfaces of the Great Pyramid, fixing accurately the days of the solstices and equinoxes. Now such porous limestone cannot be polished to reflect, or even to glitter; and a diffuse faint glare at best, without any definite limit, would be entirely useless to define a given day in the year, as here asserted. Then we read of the shadow on a face being only exact once in a century, and approximately every fourth year. As at that time of year the change of declination of the sun, by the shift of 0·242 day, from year to year is under 6′—less than a fifth of the sun's diameter—the difference between one year and another would be imperceptible to the eye.

The theories here depend on the size of the pyramid base. This was really 9069 inches; the rock sockets into which the sides sloped down below the base vary from 9119 to 9131 apart, according to their depth. To attain the theoretical base of 9141 inches, ten inches is added to the longest side without any authority whatever. The actual diameters across the pyramid show 9069 inches, but it is asserted that the sides were curved so as to bring out the corners to the amount required by the theorists.

The historical treatment likewise depends on assertion. It is assumed that a year of 360 days was used concurrently with one of 365 days, and during long ages a cycle of 103 years resulted. This is highly improbable, and there is no proof of such a mixture. The cycle of 103 years is then used in various forms, though no such cycle is known; the calendar is asserted to have been revised and altered, but there is no proof of it. We read of "fictitious chronology of the Egyptians" and "Jewish chronological forgeries" when the records are not convenient.

A typical argument runs thus: Certain dated quarry marks are assumed to be on a fixed and not a rotating calendar; that throws the quarrying into the hot season; then that proves quarrying to have been done in the hot season; and that proves that a fixed calendar was used—exactly the assertion made to begin with. The years recorded in Egyptian history are asserted to have been copied from the dimensions of the Great Pyramid in inches, though it is said that "the compilers of the kings lists added the measurements of radii to the measurements of arcs, horizontal to vertical distances, and totalled measurements in cubits together with measurements in inches." Such is what the authors have to do to produce their coincidences. All of this is introductory to the prophetic detail of the passages of the pyramid (including the exact length of the recent War), Christian chronology, and innumerable vexed questions, which are all solved by asserted connexions. It is sad to see such labour and expensive publication devoted to confusing the public mind.

Ores as Igneous Rocks.

The Ore Magmas: a Series of Essays on Ore Deposition. By J. E. Spurr. Vol. 1. Pp. x+430. Vol. 2. Pp. ix + 431-915. (London: McGraw-Hill Publishing Co., Ltd., 1923.) 2 vols., 40*s*.

THESE two interesting and suggestive volumes consist of essays on ore deposits based on Mr. J. E. Spurr's varied personal experience of American mines, which include so many types that they illustrate the chief phenomena of ore formation. Mr. Spurr shows in this work the clearness of insight, caution, and scientific ability which have made his contributions to economic geology of special value. He was one of the pioneers of the school which attaches predominant importance to igneous action in the formation of ores. He emphatically rejects lateral secretion or the formation of ores by surface waters, and also by the agency of deep-seated hot springs, as no water circulation could explain such facts as the enormous concentration of copper ores in Arizona. He insists, moreover, that ores have been made by processes that do not operate in any accessible zone of the crust, as he has not seen in the deepest mine visited any lode in process of growth.

Mr. Spurr early adopted the view, from his work in Alaska, that there is no sharp line of division between mineral veins and igneous dykes. His "alaskite," a name now generally adopted in geology for a group of quartz-alkali-felspar dyke rocks, he regards as passing imperceptibly to arizonite, or quartz veins formed as the most acid differentiation product. He calls such intermediate types vein-dykes. He unfortunately has not seen the memoir by Belt, who in 1861 advocated the igneous origin of many Australian quartz v Mr. Spurr knows that work only by the reference to Belt's "Nicaragua"; he quotes A. W. Howitt, howe who temporarily adopted Belt's hypothesis, but to wrong turning when he abandoned it and becan lateral secretionist. The origin of the injection of vein-dykes Spurr attributes, not to crustal pressure to some force inherent in the material, which he sugg is gas pressure. This force is sufficiently powerfu tear ruptures many miles in length through rocks, as evidence is clear that many ore veins did not e pre-existing fissures. He attributes the ultimate or and distribution of the chief ore deposits to the eff of magmatic migration during sub-crustal flow. recognises three types of movements: the horizo pressure around the uprisen molten masses prod overfolds and overthrusts; the blocks above an in sion are uplifted by "injection faults"; and the do sagging of the areas undermined by sub-crustal produces "adjustment faults." In connexion with intrusion of igneous rocks he discusses Daly's the that the great plutonic masses have worked their upward by overhand stoping, and also the expla tion previously adopted that some igneous rocks h replaced an equal bulk of sediment by assimilat He rejects both explanations, as in his experience field evidence gives no adequate corroboration either. The two last chapters deal with inject breccias, and ore-chimneys, which he refers to exc tional earth movements also due to igneous intrusi

Some geologists may think that the author attribu too great a rôle to igneous activity, as that theor inapplicable to some types of ore deposits; but for m of the most important ores the author's conclusi appear sound, if it be understood that his conceptio magmatic action lays stress on magmatic waters and on simple fusion. Many of the author's conclusi have a bearing on wider problems than those of pr able mining. The fore-deeps of the Pacific the aut attributes to down-sagging around the uplifted c tinental blocks, and he remarks the similarity Kainozoic volcanic activity and ore formation around the Pacific. This view attributes the exist Pacific basin as a whole to Kainozoic movement, and author remarks that we are still living in the "Terti catastrophic period." The widespread crustal distu ances are also shown by long fissures which have b proved by mining to cut across the country independ of the mountain folds. They are therefore due to fault movements that followed the last great epoch mountain folding.

Mr. Spurr's work illustrates the important li thrown by mining geology on the structure and physical geography of the earth's crust. J. W. G

Our Bookshelf.

The Calculation and Measurement of Inductance and Capacity. By W. H. Nottage. Second edition. Pp. xi+224. (London: The Wireless Press, Ltd.; New York: Wireless Press, Inc., 1924.) 7*s.* 6*d.*

MANY problems in connexion with obtaining formulæ for the inductance and capacity of various conductors and systems of conductors have recently been solved. As these solutions have usually been given in papers contributed to learned societies in various countries, it is a convenience to have them collected together in a single volume. As a rule the formulæ are very lengthy and laborious to calculate, and hence we think that more references should have been given, as in some cases the limitations of the formulæ have not been stated. We were surprised that no formula is given for the inductance of a concentric main. It is true that in most cases with low frequency it can be neglected, but in radio work it is often of importance. On p. 65 a formula is given for the *average* potential of a single straight wire. We quite fail to understand what this means, as, being a conductor, it is presumably at the same potential throughout.

We were interested to see how rough calculations on empirical formulæ gave results which agree closely with the measured values. As in the measured values the resistivity of the earth has to be taken into account, it looks as if—at least on dry days—this resistivity can be taken as constant. Numerous methods of measuring capacity and inductance are given, but it would be a help if it were pointed out which are the most suitable for special cases. Descriptions are also given of the numerous appliances that are used for making these measurements. It is surprising that in a second edition Kirchhoff's name is persistently spelt with one *h*.

Trattato di chimica generale ed applicata all' industria. Per Prof. Dott. Ettore Molinari. Vol. 1. *Chimica inorganica.* Parte prima. Quinta edizione riveduta ed ampliata. Pp. xv+680. (Milano: Ulrico Hoepli 1924.) 40 lire.

THE number of books dealing with the whole range of industries to which the description chemical is applicable is very small, and among these Molinari's work, fashioned on a new and original plan, has come to occupy a very definite and important place. The measure of its success may be gauged from the appearance, within the space of less than twenty years, of four editions in Italian, each in turn rapidly exhausted, two in English, two in Spanish, and one in French. The present volume, which begins the fifth Italian edition, contains more than 200 pages devoted to the elementary exposition of general principles, this section having undergone considerable expansion at the hands of the author's son, Vittorio. It treats likewise of hydrogen, the halogens, the elements of the oxygen group (also air and its rare constituents), nitrogen and phosphorus, etc. The very full trade statistics and other special features of the work are retained, but various subjects, such as hydrogen, sulphuric acid, and the utilisation of atmospheric nitrogen for the manufacture of synthetic ammonia, etc., are treated at greater length than formerly. The footnotes, possibly too copious in some cases, remain, and diagrams and figures are interspersed even more lavishly than in the preceding edition; the printer's work is all that could be desired. The second part of the volume on inorganic chemistry is promised before the end of the current year, and will be followed by a new issue of the companion volume on organic chemistry.

The Mongol in our Midst: a Study of Man and his Three Faces. By Dr. F. G. Crookshank. Pp. 128+29 plates. (London: Kegan Paul and Co., Ltd.; New York: E. P. Dutton and Co., 1924.) 2*s.* 6*d.* net.

DR. CROOKSHANK argues with much skill in favour of his view that in the not uncommon occurrence of Mongoloid characters in Western Europeans, of which the extreme example is the so-called Mongoloid imbecile, there is something more than a fortuitous resemblance to the racial Mongol. He adduces a large number of homologies between these abnormal cases and the Mongol races, emphasising in particular the peculiar method of sitting with the legs in the horizontal position familiar in the statues of Buddha, which seems natural to the Mongoloid imbecile, and maintains that they point to the atavistic character of this peculiarity. Mr. H. Peake has argued in favour of the introduction of a Mongoloid strain in Northern Europe in prehistoric times, and it is by no means impossible that some infiltration of Mongol blood may have followed from the racial invasions of Eastern Europe. Dr. Crookshank, however, presses his theory further and seeks to connect the Mongols with the orang, setting them against the group in which he places other races—with dementia præcox as the corresponding form of mental disease—and the chimpanzee and gorilla. It is this part of his theory which has been most strongly criticised, for, as he shows, it involved the adoption of Klaatsch's theory of two distinct parent types, one for orang and Mongols on one hand, and one for gorilla and negro on the other—a theory which has not found favour among anthropologists generally.

Transactions of the Institution of Chemical Engineers. Vol. 1, 1923. Pp. xv+120. (London: Institution of Chemical Engineers, Abbey House, Westminster, 1924.) n.p.

THE Institution of Chemical Engineers is to be congratulated on its first volume of Transactions, which reaches a high standard both in form and in contents. The volume opens with a brief history of the steps taken to found the Institution, and contains papers read before it. The first paper is a long monograph by T. C. Finlayson on industrial oxygen. In this the various known methods for the manufacture of oxygen are described and analysed both from the technical and economic aspects, and an account of original experiments is given. The results obtained were not capable of industrial application, but the paper was described as valuable in the discussion. A short contribution on absorption towers by M. B. Donald and C. W. Tyson, a study of the conditions of constant rate of flow in filter presses by M. B. Donald and R. D. Hunnemann, an outline of the present knowledge of corrosion by M. B. Donald, and a bibliography of chemical engineering literature (1900–1923) form the rest of the volume. It is evident that these contributions have been

composed in a scientific and practical style, and the volume is evidence of the really good work which the Institution may be expected to do in future in the interests of chemical engineering.

Physische Meereskunde. Von Prof. Dr. Gerhard Schott. (Sammlung Göschen Nr. 112.) Dritte, umgearbeitete Auflage. Pp. 155. (Berlin und Leipzig: Walter de Gruyter und Co., 1924.) 1.25 gold marks.

THIS is a very small book. but the amount of information that it contains is extraordinarily great. The author does not discuss the whole subject from a general point of view so much as give a concise exposition of each section of physical oceanography, together with the methods employed in obtaining the data.

The book is divided into three sections. The first deals with the ocean as a whole; the depth and character of the sea-bottom are discussed, and its general morphology in relation to the land is described. Section 2 deals with the properties of sea-water, and is divided into subsections on the physics and chemistry of sea-water, on the distribution of temperature in the sea, and on the ice found in the sea. The last section describes the various kinds of movement occurring in sea-water. The theory of wave motion in the sea is discussed in a very interesting manner. The last two chapters on the tides and on the ocean currents are rather disjointed, because the facts are first set out by themselves and their explanation is given afterwards in the form of explanatory paragraphs.

Organic Syntheses: an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Vol. 3. H. T. Clarke, Editor-in-Chief. Pp. v+104. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1923.) 7*s.* 6*d.* net.

VOL. 3 of this series fully attains the high standard reached in the two previous volumes. The preparations described are models of careful work and explicit detail. For the use of students the book is excellent, though the quantities employed in the preparations are somewhat large, and changes in these quantities sometimes imply considerable alteration in the other experimental details, as the reviewer found in the preparation of allyl alcohol (vol. 1, 15-19).

The chief purpose of the series is to place on record certain well-tried and proven methods of preparing intermediate compounds used in research and technical work, and the volumes so far produced justify the work of the contributors. It seems a pity that more contributors have not added to these volumes some of the many methods of preparing products necessary for the prosecution of research which have been improved in their laboratories but are not generally known.

The method of indexing is novel and should prove useful. L. C. N.

Amurath to Amurath. By Gertrude Lowthian Bell. Second edition. Pp. xvii+370+105 plates. (London: Macmillan and Co., Ltd., 1924.) 21*s.* net.

A SECOND edition of Miss Bell's account of her journey from Aleppo to Baghdad, and thence to Konia, is very welcome; for surely "Amurath to Amurath" deserves to rank with the best of travel books. Bell's keen observation, penetrating judgment, profound archæological knowledge, which are comb with a gift of graphic narrative, are here perhap their best. She is equally at home in describing ancient Mesopotamian site and in recording the go of the bazaar. Her thumb-nail sketches of the pe she met are vivid and compact with an imagina insight into the soul of the Eastern races. As book was first published in 1911, soon after the rising of the Committee of Union and Progress and advent to power of the young Turk, its polit interest, when read in the light of subsequent eve scarcely need be emphasised.

A Handbook of Telephone Circuit Diagrams: Explanations. By John M. Heath. Pp. x+ (London: McGraw-Hill Publishing Co., Ltd., 19 12*s.* 6*d.* net.

To any one who desires to acquire a good pract knowledge of the art of telephony we can recomm this book. In order to get the full benefit from however, he should first study a good element treatise on the subject. Every telephonist has spend much time and study in puzzling out the vari wiring diagrams of the different units in a teleph system. In this book the circuit diagrams are predominating feature. They are arranged in a logi and progressive manner, following generally the histori development of the art. Having once understood diagrams of the component parts, it is easy to und stand the wiring diagrams as a whole. The symbols well chosen and a study of the circuit diagrams will g the necessary complementary knowledge to that giv in text-books.

Evolution, Knowledge and Revelation: Being Hulsean Lectures delivered before the University Cambridge, 1923–24. By the Rev. Stewart McDowall. Pp. xviii+118. (Cambridge: At t University Press, 1924.) 6*s.* net.

THOUGH dealing with problems of religion and phi sophy, and leaning entirely to an extreme form metaphysical idealism, this little book, consisting four lectures, is thoroughly scientific in spirit and method. The lectures aim, the author tells us, establishing a theory of knowledge based on the fac of evolution and in sympathy with the spiritual int pretation of Nature by the best metaphysical systen Though necessarily slight, the book is never dull.

Economic Geography. By Prof. R. H. Whitbeck a Prof. V. C. Finch. Pp. x+558. (London: McGra Hill Publishing Co., Ltd., 1924.) 17*s.* 6*d.* net.

PROFS. WHITBECK and FINCH'S volume is a well-writt text-book on orthodox lines, which result in the field economic geography being somewhat restricted. T United States and Canada are treated very fully as o economic unit, followed by a summary of Canad These chapters contain much useful material, but t rest of the world, with the exception of Central a South America, receives too brief a treatment for t book to prove acceptable on the eastern side of t Atlantic. The sketch maps and diagrams are i structive, and there are bibliographical references.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

International Co-operation in Phenological Research.

THE need for international co-operation in recording the dates of special events in the seasonal development of a few representative species or varieties of native and established cultivated plants will be recognised when the facts are considered, that the time of such events as the opening of leaf and flower buds, the completion of growth, the ripening of fruit, the harvesting of crops, etc., are true expressions, not only of the influence represented by the three important elements of climate, temperature, precipitation and sunshine, but, in addition, that represented by all other elements in the physiographic complex of the environment affecting in any degree the seasonal development of a plant. When it is considered, further, that the correct interpretation of the geographic and economic significance of the average date of the same event, at representative places within the geographic range of the species, is an element of a true index to the bioclimatic character of each place and the immediate region represented, it will be realised that such records are of the greatest importance, especially in connexion with those of temperature and precipitation, in the study of geographic distribution of plants and animals, types of climate, cultivated plants, world agriculture, etc.

While the influence of climate and weather conditions upon native plants and cultivated crops have been noted from the earliest days by individual observers, it is only in the last fifty years that attempts at united efforts, such as with the records of temperature, or pressure, and, above all, rainfall, were sufficiently organised anywhere to form the branch of science designated as "phenology."

Yet its importance to agriculture and horticulture is great and has already proved to be of material commercial value. This is especially the case in the United States through the Department of Agriculture, where it has received great attention under the leadership of Dr. A. D. Hopkins. The same is true, if to a less recognised extent, in the British Isles, Central Europe, Belgium and Holland (under Dr. Ross), the other countries actively carrying on similar work. In Germany, under Hofman and Ihne, it has been carried on unofficially for more than forty years on one systematic plan confined to flowering plants, especially trees and shrubs.

British co-ordination began in 1877 under two distinct organisations. The smaller was carried on in the *Natural History Journal* from 1877 to 1898, as "Floral Calendar" and "Migrant Table," twenty year averages being obtained. But more important and permanent is the phenological work under the auspices of the Royal Meteorological Society, under the successive leaderships of Rev. T. A. Preston, Mr. Edward Mawley (by whom it was reorganised in 1890), Messrs. Clark and Adames, and the present committee. Flowers, birds, and insects are included in the records, but fourteen of the first form the most essential part.

The results of this work as represented by averages of the essential records have been correlated with the averages of the three most effective climatic elements, temperature, rainfall and sunshine, and thus form a comprehensive interpretation of the various climatic regions and areas of the British Isles and their relation and relative importance to our agriculture and horticulture. They also lend themselves to important geographical correlation with the countries named above, and, not least, with the exhaustive work in the United States. We therefore venture to suggest that the time has come for similar systematic work to become world-wide.

Special mention must be made of the Hopkins' "Bioclimatic Law," worked out for the United States, but through which results obtained in one country can be applied elsewhere, with considerable confidence, if equivalent phenological records are available.

It is for such reasons that the present appeal is made, for co-operation in the establishment of similar work through the Dominions and elsewhere, especially throughout Europe and extra-tropical Asia,[1] whereby accurate records may accumulate as a basis for interpreting the relative influence of the local and regional climate, weather, and seasons on the periodical events in plants and animals, seedtime, and harvest, etc. Our suggestion is that such world-wide inauguration of this work, particularly in extra-tropical countries, will quickly provide data of great scientific and economic value towards the advancement of world agriculture. After the lapse of ten years or so, sufficient data should exist for inter-regional correlation, whereby, under the Bioclimatic Law referred to above, results obtained from similar records elsewhere could be given universal application.

Such correlation is yet in its infancy, but has already been tentatively extended from the United States to Great Britain[2] and Western Europe, although hampered by the divergent character of the records in different countries.

This suggests that, in further development, a more uniform and simplified method is most desirable, including at first a very limited number of common and widely distributed species or varieties[3] of native or cultivated plants and only the more essential events.

Our own method of working is based upon a schedule sent out each year to the observers. No two countries can use identical lists, and each country or province would need its separate organisation. But in selecting the series best covering for the given region the full period of growth and maturity, the inclusion of some identical flowers of widespread range would have great value for such possible correlation. The British list suggests a selection of some of the following as possible for common ground: hazel, dog-rose, snowdrop, blackthorn, horse-chestnut, oxeye daisy, and hawthorn. It may prove desirable to add a few more of widespread range to the lists now in use, such as the first shooting and first unfolding of the basal pinnæ of bracken, flowering of almond or peach, silver birch, locust tree (white acacia): possibly the flowering of some field crop and weeds of cultivation. Suggestions as to any such adapted for observation in other areas would be helpful.

It occurs to us that as a beginning some one official or investigator at each of the more representative meteorological and agricultural stations and other institutions of public service in scientific research, as well as private workers, in each of the principal countries might be specially interested in making consecutive observations. It would require little time and effort to record the dates of the more

[1] Tropical regions present far more complicated problems, yet it seems a pity to exclude them.
[2] Journal of the Washington Academy of Science, 1921, pp. 223-227.
[3] With varieties, the same must be selected for all stations.

important seasonal events of some common plant or plants, such as the opening of the leaf and flower buds on a tree or shrub, observed from the office window, the ripening and harvesting of a crop in an experimental plot or on neighbouring farms, yet such records would serve not only as a matter of personal interest but also, through an interchange of records each season, and ultimately the publication of averages, they would soon furnish a source of information which would be of inestimable value to investigators of the problems of local and world agriculture.

1925 completes the thirty-five years of observations on one system in the British Isles, a period well recognised as of meteorological importance, and with its close it may be advisable to introduce modifications. Therefore we are the more anxious to associate ourselves with any wider developments which may be evolved, and we make an earnest appeal for such co-operation.

The interest manifested by replies to these suggestions from persons in different countries will indicate whether or not further efforts towards the formulation of a uniform plan of records and co-operation will be justified. We ask such to communicate with us.

Copies of our last Report illustrating the work carried on in Great Britain will gladly be sent to indicate its character. Moreover, many readers of NATURE in this country[4] will know individuals and societies whom it would be well to approach, and the names and addresses of such will be most welcome. No doubt there are many solitary workers unaware of what is being done, for, as Dr. Bos has pointed out, no journal of phenology at present exists. The help also of residents in the homeland would be most welcome.

The fact that the work in the British Isles has been under the auspices of the Royal Meteorological Society is to a certain extent accidental. For it concerns a far wider circle than meteorology, particularly botanical, agricultural, ecological, biological, climatic, and geographical interests. For this reason we are acting after consultation with, and approval of, not only the well-known phenologists already named, but also Mr. J. C. F. Fryer, of the Biological Department of the Ministry of Agriculture and Fisheries; Mr. J. Burtt Davy, lately Chief of the Division of Botany and Government Botanist, Union of South Africa; Mr. A. G. Tansley, Prof. E. J. Salisbury and Prof. F. W. Oliver, through whom we have the support of the Ecological Society. We have also the full approval of the Council of our own Society through Capt. C. J. P. Cave, our president, and Mr. R. H. Hooker, a recent president.

Communications may be addressed to J. E. Clark, 41 Downscourt Road, Purley, Surrey, England.

NOTES ON THE BIOCLIMATIC LAW.

THE writer has had the privilege of seeing the original draft of Mr. Clark's letter to NATURE with reference to "international co-operation in phenological observations," and he is heartily in sympathy with the ideas covered in this initial movement towards the extension of the service to world interests in agriculture through observations and research in this relatively unrecognised branch of natural scienc

In further reference to the Bioclimatic Law me tioned by Mr. Clark, it may be stated that it w from studies of the relation of latitude and altitu to the difference in time of the emergence of t Hessian Fly, and its attack on wheat sown at giv times, that the idea of a natural law was suggest in 1895, and that the development of this law h been based largely on a comprehensive study of t dates of seeding and harvesting winter wheat with the distribution of this crop in the United States on general and specific and phenological observatio and studies in this country, and utilisation of t published records of the comprehensive work in t British Isles and Germany. On account of the meag or lack of phenological records from other countrie it has been necessary to rely on published climati biological, geographical, and agricultural data for t inclusion of most of the other countries of the wor in a comprehensive study of the relations of the la to world agriculture and other human interests.

While these additional data have served as im portant elements in the development of the law an its application to research and practice, it is in creasingly apparent that phenological data from th different countries are far more important.

Briefly stated, the Bioclimatic Law is one of effect i response to the laws of causation represented by th sun, the motion of the earth, unequal distributio of land and water, and the varying physiographi features of the continental and insular areas. Th law of effect is interpreted as requiring a broa general, country-wide variation in time and tem perature, as related to types of equal phenomena c life and climate, at a unit constant rate per distanc in degrees of latitude, poleward and equatorward longitude, east and west; and feet or metres of alt tude above sea-level (as four days of time betwee the dates of the same phenological event to on degree of latitude, five degrees of longitude (earlie from west to east), and four hundred feet of altitude).

The application of these principles in the study o the geography of life and climate, designated as th science of *Bioclimatics*, is in accordance with th principle of the *variable* and the *constant*, in whic the recorded quantity in time, temperature, etc., fo a given geographic position is the *variable*, and th corresponding quantity computed for the same posi tion from the unit constant requirements of the law is the *constant*.

The variation of the recorded quantity from it constant represents a *Bioclimatic Index*, or measure of the intensity of the local and regional influences o the causation complex relative to that determine for a continental or intercontinental base. Thus th bioclimatic index for a number of representative positions within a local or general region will indicate the trend and extent of the variations from the requirement of the law and consequently serve, in connexion with information on the topography and precipitation, as a basis for interpreting the bio-climatic character of the region, as to the type of climate and corresponding life that may be expected to prevail; in other words, indicate the life and climate, or bioclimatic zone, that is represented, which in turn will indicate the kinds of crops that can or cannot be grown, so far as controlled by tem-perature and precipitation.

Thus if we had, in addition to the already available meteorological data, a long-time series of pheno-logical records from representative positions in the

[4] Incidentally, we would point out that fresh British observers are always welcome. Our appeal through the pages of NATURE two years ago gave us a most satisfactory accession of stations.

[1] Suppl. No. 9, *Mon. Weather Rev.*, U.S. Dept. Agric. Weather Bureau 1918.

different countries of the world, their bioclimatic zones could be predicted and mapped (so far as maps of topographic surveys are available), as has been demonstrated by a detail map of the bioclimatic zones of the United States and preliminary maps of the thermal zones of the British Isles, Germany, and Australia. A. D. HOPKINS.

Organisation in Chemical Societies.

As one who has some direct knowledge of the affairs of the Chemical Society, I should like to reply to the letter from Dr. M. W. Travers which appeared in NATURE of October 4. Dr. Travers has presented a singularly one-sided statement of the position, for in his endeavour to prove that the societies give an inadequate return for the subscriptions received, he omits essential points which any fair-minded man would take into consideration before giving a verdict on that charge.

In the first place, Dr. Travers criticises adversely the decision to make an extra charge for the Chemical Society's "Annual Reports," since, in his view, students, to whom this publication particularly appeals, will be thereby discouraged from joining the Society. He omits to mention, what is equally relevant, that, for the present, new fellows are not required to pay the entrance fee of 3*l*.—a financial alleviation which has been introduced mainly to meet the case of the young chemist, and ought in fairness to be set against the new charge for the "Annual Reports." The necessity of paying 3*l*. in addition to the first annual subscription has, quite naturally, prevented many students and junior chemists from joining the Society.

When the Chemical Society's Library, with the unique and development of which all the leading chemical organisations are now associated, is put on record by Dr. Travers, because it is not "in any way comparable with the Patent Office Library." Against this unwarranted and contemptuous reference to the Library of the Chemical Society I should like to put the plain fact that, since the opportunities for using the Library were extended some years ago, the annual number of readers has increased from between two and three thousand to between six and seven thousand, and is rising steadily. Further, the Patent Office Library, however useful to Londoners, cannot serve chemists who reside in the provinces, whereas a large proportion of the books and journals in the Chemical Society Library can be borrowed, either directly or through the post. The extent of the availability of the Chemical Society Library is not generally realised.

As to abstracts, it is, of course, well known that the American publication covers a much wider area than the two sections of the British abstracts combined, but that is not necessarily an unmixed advantage. Against the narrower scope of the British publications, however, it is only right to set the fact that abstracts appear there more promptly than in *Chemical Abstracts*. Some papers, more particularly those from American sources, are reported earlier in *Chemical Abstracts*, but the majority are abstracted first in the British publications. The more prompt appearance of the British abstracts is a valuable feature which deserves to be emphasised.

Those who give time and thought to the affairs of the chemical societies have, I believe, no objection to candid criticism, provided it is just. In connexion with abstracts, for example, the desirability of improvement and co-ordination is recognised, and I would invite Dr. Travers (and any other critics) to submit to us any really *constructive* suggestions, not in the spirit of his letter, but in the spirit of co-operation. As chairman of the Bureau of Abstracts, I guarantee that any such practical suggestions will receive fair consideration. JAMES C. PHILIP.

Transformations of Elements.

THE theory of allotropy, starting from the supposition that every state of aggregation (phase) of a so-called simple substance (system of one component) is complex, that is, consists of different molecular species, and stating that behaviour as a simple substance is only due to the rapid establishment of equilibrium between these different kinds of molecules (inner equilibrium), has led, when applied to metals, to a theory of electromotive equilibrium. Herein it is assumed that with metals the complexity consists in the existence of atoms, ions (of the same or of different valency) and electrons. These various particles give rise to an inner equilibrium which in the simplest case is represented by the formula:

$$M_s \rightleftarrows M_s^{\nu\cdot} + \nu\Theta_s,$$

in which ν indicates the number of positive charges on the metal ion, and the suffix s that the solid state is being considered.

From this point of view, polarisation occurs if the withdrawal of electrons and the combined ejection of ions, respectively the supply of electrons and the combined deposition of ions, takes place more rapidly than the establishment of the inner equilibrium. If there is no formation of molecules, this can only be due to a too slow course of the reaction mentioned above.[1] By sending a metal rapidly into solution, for example, by means of an electric current, according to these considerations the metallic surface will become impoverished as regards electrons and ions, and the theory shows that in this case the metal will behave electrolytically as a more noble metal, which normally contains a smaller electron- and ion-concentration. Consequently, a base metal temporary can transform superficially into a pseudo-noble state by rapid anodic solution.

Now the question arose if experiments in the same direction, but arranged differently, could possibly lead to wider and deeper disturbances. In connexion with secondary phenomena, such as the discharge of anions, contact with an electrolyte is an important hindrance to creating a powerful disturbance. This difficulty is removed, of course, if, instead of a liquid, a rarefied inactive gas is used. That also, in inactive gases, metals show polarisation phenomena, is found by Gaede and others, but while by their point discharges only small current densities were acting, the disturbance could not be large. It is clear that the best method to obtain a large disturbance is to use the electric arc-flame. For several years I have therefore intended to study different metals, in a vacuum lamp, in the hope that on increasing the current density the disturbance of the metal would become so large, that not only the valency electrons, on leaving their orbits, should be snatched away and thus prevented from falling back, but also the deeper electrons, and perhaps those of the nuclei, whereby, in the latter case, also α-particles could be split off.

Much occupied by other investigations, the experiments mentioned above were delayed. I was greatly interested, therefore, to read, in July last, the communication of Prof. Miethe on the transformation of mercury

[1] See "The Theory of Allotropy," p. 130.

into gold in the mercury lamp of Jaenicke, when burning overcharged. I resolved to return to my proposed experiment, and I did not intend to study mercury but lead. In accordance with this original scheme, I have now carried out some experiments. Peculiar difficulties arise, because lead fuses at 327° C., and also because lead, solidified in a quartz vessel, breaks the vessel if heated again. Notwithstanding this, we succeeded in constructing a satisfactory lead quartz lamp (Fig. 1). The two legs A and B end in two narrow tubes, in which two steel electrodes are cemented with sealing wax. Around these cemented ends two little copper water coolers G and H are inserted, preventing fusion of the sealing wax. Vessel C is the store vessel, into which the pure liquid lead is poured, after which the open end is sealed off. An electric furnace around C keeps the lead liquid. Tube D, which is bent, contains a capillary F and ends in a cock K. The free end of the cock is connected with the mercury diffusion pump.

When a high vacuum is reached, the vessel C containing the lead is heated to redness with the Bunsen burner, with the result that all oxide is dissociated, and that

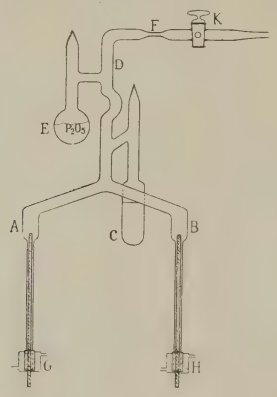

FIG. 1.

the metal, freed from all gases, has a surface as smooth as pure mercury. After closing the cock K and breaking the connexion with the pump, the apparatus is inclined, and the liquid lead is run into the two legs of the lamp. Now the lead is once more heated to redness in the two legs to drive out the gases from the steel electrodes. Many gas bubbles escape now and the apparatus is evacuated once more. After that the lamp is ready, and can be used in the same way as the mercury lamp, with this difference only, that removable radiating coolers cannot be placed around the legs A and B before the lamp is working. At the end, the liquid lead is again brought into the vessel C, which is continuously heated by the little electric furnace at 350°.

Because bismuth is also an element which is to be considered here, and the system lead and bismuth has a eutectic point at about 120°, it was of interest also to try this eutectic composition. We found that this alloy can be used in exactly the same way.

It is clear that the investigation of these lamps is not only of use to show whether transformations of elements can be realised, but also to study the arc spectrum. The lamp here described, like the vacuum mercury lamp, burns at relative low voltage; we are constructing another lead lamp which, like Jaenicke's lamp, burns at higher voltage. We hope to be able to communicate some results shortly.

An Approximation to the Probability Integral.

THE probability integral

$$\Theta(t)=\frac{2}{\sqrt{\pi}}\int_0^t e^{-t^2}dt$$

can be represented by the simple approximation

$$\frac{6}{\sqrt{\pi}}\cdot\frac{t}{3+t^2}=3\cdot385\frac{t}{3+t^2}=1\tfrac{1}{8}\frac{t}{1+\frac{1}{3}t^2}$$

over such a range ($t<\sqrt{3}$) as to make the approximation useful to the statistician and others whose problems do not require great accuracy.

Since

$$\Theta(t)=\frac{2}{\sqrt{\pi}}\left(t-\frac{t^3}{3}+\frac{t^5}{10}-\frac{t^7}{42}+\ldots\right),$$

and ($t<\sqrt{3}$)

$$\frac{6}{\sqrt{\pi}}\cdot\frac{t}{3+t^2}=\frac{2}{\sqrt{\pi}}\left(t-\frac{t^3}{3}+\frac{t^5}{9}-\frac{t^7}{27}+\ldots\right),$$

$$\Theta(t)=\frac{6}{\sqrt{\pi}}\cdot\frac{t}{3+t^2}-\frac{2}{\sqrt{\pi}}\left(\frac{t^5}{90}-\frac{5t^7}{378}+\ldots\right).$$

For small values of t the approximation is evidently good. Beyond $t=\sqrt{3}$ it clearly fails. But at $t=\sqrt{3}$ the error is within one per cent. At first the approximation is slightly in excess of the function, but the error reaches its maximum near $t=1\cdot2$, vanishes after $t=1\cdot5$, and then becomes negative. As $t=\sqrt{3}$ means more than 3·6 times the probable error, the range of useful approximation is quite considerable.

For some purposes it will be convenient to write

$$t=\sqrt{3}\tan\tfrac{1}{2}\phi,\quad \phi<90°,$$

$$\Theta(t)=\sqrt{\frac{3}{\pi}}\sin\phi=[-0\cdot0100]\sin\phi.$$

Thus for $\Theta(t)=\frac{1}{2}$, $\phi=30°\cdot77$ and $t=0\cdot4766\ldots$ as compared with the true value $\rho=0\cdot4769\ldots$ Further comparison is given in the following table:

ϕ.	t.	t/ρ.	$\sqrt{\frac{3}{\pi}}\sin\phi$.	$\Theta(t)$.	Diff.
60°	1·000	2·097	0·8463	0·8427	+0·0036
69·8	1·208	2·533	0·9171	0·9125	+0·0046
83·1	1·535	3·219	0·9701	0·9701	0·0000
90	1·732	3·632	0·9772	0·9857	−0·0085

Beyond the last point the approximation allows for 23 cases per 1000, while the normal law allows 14. As abnormally large deviations are often in excess of expectation, this is no bad thing. For approximate calculations of this kind it is well to remember that the reciprocal of 2·1 is 0·4762, which is very nearly the value of ρ.

It is evident that

$$\int_0^t\Theta(t)dt=\frac{3}{\sqrt{\pi}}\log_e(1+\tfrac{1}{3}t^2)$$
$$=3\cdot897\log_{10}(1+\tfrac{1}{3}t^2)$$

is a very close approximation over the range $0<t<\sqrt{3}$.

A far closer approximation to the error function has been given by Mr. H. B. C. Darling (*Quart. J. of Math.* xlix. p. 36), but its form makes it unsuitable for the purely practical purposes here contemplated.

Is *Orchis Fuchsii* (Druce) a Valid Species of Orchidaceæ?

THERE has for some time been going on a controversy among botanists as to whether Linnæus in establishing his species *Orchis maculata* omitted from, or intended to include within, it a very closely related form collected by himself, which has been raised to specific rank by Dr. Claridge Druce as *O. Fuchsii*. The question whether the latter is only a variant of

the former or not appears to depend on whether Linæus in his diagnosis of *maculata* intended the description of the middle lobe of its trifid labellum to apply to one or both.

In reading the discussion, I was reminded of some observations—of interest perhaps to the disputants—which I made on this orchid in 1922 during a stay at Heathfield in Sussex. The banks of the railway between Mayfield and Heathfield, and of the high road from Brighton through the latter place to Kent, are profusely empurpled in its season with the spotted orchis. Long habit induces me, whenever in the country, to gather specimens of the flowering plants I meet with, for the pastime of discovering any variation from type, especially of orchids, to record the proportion of cross to non-fertilised flowers. I had brought to my rooms, therefore, handfuls of the orchid.

While on the majority of the plants, gathered from the *same* communities—all to me obviously *maculata*—the lateral segments of the labellum were normal in being larger than the central one, which, though somewhat less in breadth, did not much, if any, exceed it in length, I was nonplussed—as notes and a rough sketch made in my journal at the time indicate—to find in a considerable number that the central lobe of the florets, differing from the figure in Fitch's illustrations (the only botanical work I had with me), was conspicuously longer, very sharp pointed, and, both actually and in comparison with its fellow side-lobes, much narrower than in the others. I believe (without being absolutely certain on the point) that florets with the more normal labellum and those with a long-pointed mid-labellar lobe occurred together on the same spike. As I was then unaware of the controversy I did not make the precise observations I might have done, thinking that the differences were—as I incline still, even if they occur on separate plants only, to believe—merely varietal. *O. Fuchsii* would, in my amateur opinion, appear to be only a variety (not an oft-recurring sport) of *O. maculata*.

HENRY O. FORBES.

Deanway, Beaconsfield, Bucks.

Regularities in the Spectrum of Ionised Titanium.

THE spectrum of ionised titanium is very interesting, owing to the fact that a large number of chief lines lie between $\lambda = 3000$ and $\lambda = 4500$, and hence enhanced lines of titanium form a very characteristic feature of the spectrum of the solar chromosphere and the stars. As regards the chromospheric spectrum, lines of Ti^+ at $\lambda = 3685$, 3759, 3761 reach a height of 6000 km., and many other lines reach heights exceeding 1500 km., while resonance lines of titanium (=5193·12, 5173·92, 5210·59)—following the classification given by Kiess and Kiess—reach heights of 50 km. only. In this respect the behaviour of titanium is parallel to that of calcium, both as regards the ordinary as well as the enhanced lines, though owing to the larger atomic weight, titanium fails to reach the great height of Ca^+, as given by the H and K lines. Also no lines of Ti^+ dominate the spectrum to the same extent as the H and K lines dominate the spectrum of Ca^+.

Recently King has published a very thorough study of the spectrum of titanium in the furnace, and the arc. This has enabled me to study the regularities in the spectrum of Ti^+. The chief lines can be arranged as quartet groups, and the lowest levels are given by three p-terms with the frequency differences 81 and 509. The structure fits in admirably with the rules given by Lande (*Zeitschrift für Physik*, vol. 1); for, according to the displacement rule of Sommerfeld and Kossell, the spectrum of Ti^+ ought to be similar to that of scandium, which has been shown by Catalán to consist of quartets and doublets. The separation of the p-terms, according to Lande, ought to be as 5 : 3, while 860 : 509 = 5 : 2·96. The separations of the d-terms ought to be as 7 : 5 : 3, while we have found them to be 98·40 : 69·46, 45·86 = 7 : 5 : 3·1. The precise value of the ionisation potential of Ti^+ has not yet been obtained, but it seems to be about 13 volts. The ionisation potential of titanium itself has been shown by Kiess to be about 6·8 volts. This is in accordance with the fact that in the spectrum of stars the behaviour of T^+ and Ca^+ are almost parallel—*vide* W. J. S. Lockyer, Mon. Not. Roy. Ast. Soc., vol. 81, who finds that titanium lines are stronger in F5G stars (ϕ-Cassiopeia) than in A2F stars (α-Cygni).

A full account of the work will be published very soon.

NALINI KANTA SUR.

Allahabad,

"Evolution at the Crossways."

I MUST protest that from the notice of my book on "Evolution at the Crossways," in NATURE of October 4, no reader can get a correct impression of what my theory really is.

The reviewer makes me speak of "righteous" or "unrighteous" insects, for example. But I have specially guarded myself (p. 11) that the bio-morality which I posit does *not* involve conscious morality or really ethical praise or blame. I speak (only rarely and in a general way) of "biologically" righteous and "biologically" unrighteous conduct, *i.e.* in respect of the interdependence of life, of mutual relations. More commonly, however, I use instead the terms "cross-feeding" and "in-feeding" species. My thesis is that "Nature abhors perpetual in-feeding"—the analogue of Darwin's aphorism regarding "in-breeding." The difficulties the reviewer has with my theory are more apparent than real. Have his sharks or echinoderms anything to boast of? Have the molluscs, numerous though they be? They reached their highest development in the massive and almost mindless cuttle-fish. Most of these are indeed predatory and carnivorous. What has it led them to?

The critic's "agriculture" argument is beside the point, unless he intends to be more anthropomorphic than I am. Surely species may be retrogressive, though still of some use to man.

H. REINHEIMER.

103 King Charles' Road,
Surbiton, Surrey,
October 9.

MR. REINHEIMER may justly claim that only from his words can a reader get a correct impression of the theory. On page 12, we read: "Everything abnormal and pathological is due to biologically unrighteous, *i.e.* fundamentally predatory behaviour. Although predaceous species may apparently, and for a time, live quite well, yet their temporary success is at the expense of permanent survival." On p. 186, "All predaceous animals are on the road to ugliness." On p. 87, "The wages of biological sin are: deformity, inferiority, disease, degeneration, death."

There are no apparent difficulties with Mr. Reinheimer's theory. Sharks and echinoderms may "boast" of having been biological sinners and "in-feeders" since Silurian times without incurring any of the five penalties of p. 87. The brain of the cuttle-fish is not less developed than that of herbivorous molluscs, The inferiority of eagles and whales is not self-evident. nor the deformity of cats and sea-birds, nor the ugliness of mackerel and king-fishers. G. P. B

The Glow of Phosphorus.[1]

By the Right Hon. LORD RAYLEIGH, F.R.S.

THE discovery of phosphorus was one of those which is associated with the transitional period when magic and science flourished to some extent side by side, and when the borderline between them was not very well defined. The discovery seems to have been made by the alchemist Brand, of Hamburg. But in those days scientific discoveries were often cherished as valuable secrets, not so much for their commercial value as for the sense of superior knowledge and power which their exclusive possession was supposed to give. Scientific secrets are sometimes jealously guarded now, but not for this reason. When reticence is observed, it is for the less romantic motive of commercial advantage. In the absence of this motive, the scientific men of to-day tell all they know, and tell it without delay.

The subject of phosphorus emerged into daylight in 1678, when Kunkel, who had learnt the secret by word of mouth, made it public. In 1780 the Hon. Robert Boyle deposited a paper on the same subject with the Royal Society. He had worked it out anew, without more than the hint that phosphorus came from an animal source.

It was a long time before the nature of the luminosity of phosphorus was finally settled. The early investigators not unnaturally classed it with the substances which become luminous by exposure to light, such as impure calcium sulphide. This notion survives in the word "phosphorescence," which is after all purely descriptive of the property of giving light. Now, however, the word is usually reserved for the cases like calcium sulphide. Phosphorus is not commonly spoken of as phosphorescent; its luminosity, as every one now knows, is due to slow combustion in the oxygen of the air. It took a long time to prove this, and the question was still in a measure open down to the year 1874. The doubt arose partly from the extremely small quantity of oxygen necessary to make the phosphorus visibly luminous. Accidental leakages may thus confuse the question. Another puzzling circumstance was that when oxygen was substituted for air the glow was extinguished. This can be shown by means of a large flask containing phosphorus dissolved in olive oil. Though the flask may be full of oxygen, the phosphorus is quite dark. When, however, some of the oxygen is removed by means of an air-pump, the phosphorus suddenly blazes out at a lowered oxygen pressure. The same result may be shown by substituting air for oxygen.

This is not the only peculiar thing about the behaviour of glowing phosphorus. When a piece of cotton wool moistened with bisulphide of carbon is held above a dish containing an oily solution of phosphorus, so that the vapour can stream down from it on to the glowing surface, the vapour has an almost magical effect. It stops the phosphorus glowing altogether. In a little time, the small quantity of vapour gets dissipated, and the phosphorus glows again.

Bisulphide of carbon is only one example of many vapours which will behave in this way. Ammonia, camphor, ethylene, turpentine, and essential oils generally, will do the same thing, though they vary widely as to their effectiveness. The majority of permanent gases have little effect in this way, though I am not prepared to say what they might do at high pressure.

It will probably be admitted on consideration that the action of oxygen is not essentially different from that of the other inhibiting substances. As will be explained shortly, the action occurs between oxygen and phosphorus vapour. A little oxygen is necessary to unite with the vapour as it comes away from the phosphorus surface, but the density that is of any use in this way is very small. If, for example, we have a millimetre of oxygen pressure, there will be in the gas space many oxygen molecules for one phosphorus molecule, and a further increase can scarcely promote the combustion. The action of a great excess of oxygen, as when we admit it up to atmospheric pressure, must be something quite different. There is therefore no real paradox in the quenching by an excess of oxygen. Perhaps this analogy may help to explain the action: A man cannot live without water; if he does not get it he will die of thirst; yet if he swallows too much he may be drowned. The water acts in quite different ways in the two cases, and so does oxygen in contact with phosphorus.

Another very strange thing happens when phosphorus is used to get rid of the last traces of oxygen in gas analysis. Suppose that we start with air in a confined space, and put a piece of phosphorus into it. At first the light is confined to the surface, but as the oxygen approaches exhaustion, the light is seen to become diffused throughout the volume of the vessel. It is easy to understand why this happens. Phosphorus is appreciably volatile at the ordinary temperature. When the surrounding oxygen is abundant it snaps up the phosphorus vapour at once, before it can diffuse away from the surface. But when oxygen becomes scarce the phosphorus has the chance to get some distance before this happens. This much is easy to understand. But if we look closely we see that the glow is not steady, but shows moving clouds of luminosity, most curious to watch. Any one can readily try this experiment. Nothing more is required than a piece of phosphorus stuck on a wire and introduced into a bottle standing inverted with its neck under water.

My own work on the subject started from this experiment, which I tried to develop into something more definite than clouds of vague outline moving in an ill-defined path. Fig. 1 shows an attempt in this

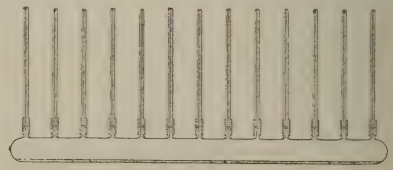

FIG. 1.

direction which had some success. The idea was to constrain the luminosity to move in one direction only. The horizontal tube has a layer of phosphorus lying along the bottom. The long narrow vertical tubes allow air to leak in slowly. When the oxygen originally in the tube is nearly exhausted, luminous pulses are

[1] Discourse delivered at the Royal Institution on Friday, June 6.

e to spring into existence at the side openings, to divide, and to travel along the tube. Usually this happens predominantly at one or two particular places. Pulses travelling along the tube in opposite directions kill one another when they meet.

This arrangement was set up in a dark room, and watched from time to time. After the lapse of a week or more a change was noticed. Although nothing had

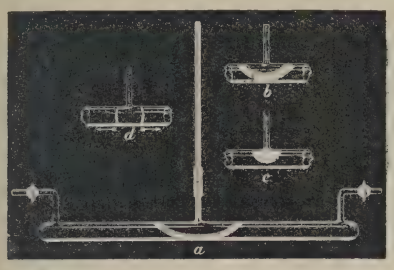

Fig. 2.

been touched, the movements were less lively, and the light had become stationary in places. Finally, all movement ceased.

What could be the explanation of this? The phosphorus had originally been melted into the tube under water, for safety, and the water was, so far as possible, poured off. But, of course, it could not be got rid of completely in that way. The oxides of phosphorus produced by the combustion are greedy of water, and these had gradually dried the tube. On adding water the movements began again.

The next illustration (Fig. 2) shows a similar tube, with only one capillary entrance at the middle. It was pumped out on the mercury pump in the first instance, and filled with nitrogen. A perfectly steady cloud of luminosity is seen when atmospheric oxygen begins to mingle with phosphorus vapour; *a*, *b* and *c* show successive stages as the oxygen influx is increased. If a drop or two of water is added a succession of luminous pulses starts at the side entrance, divides, and travels in opposite directions along the tube (Fig. 2, *d*).

Why does the luminosity move when there is water, and remain steady when there is none? It is evident that the travelling pulses represent the propagation of a wave of chemical action along the tube. There is a mixture of oxygen and phosphorus-vapour ready to unite. It does not at once do so, but chemical union is determined by the passage of the wave, just as in the firing of a train of gunpowder. Nothing of this kind seems, however, to happen in the absence of water. The water holds up the combustion.

Now that matters have been brought to this point, we may recall the experiment in which phosphorus was prevented from glowing by the presence of bisulphide of carbon vapour. Water, it is evident, acts like the other inhibiting substances, but less powerfully. This naturally suggests that we might get the travelling pulses on a more impressive scale by using a more powerful inhibitor than water. It is not desirable to have too powerful an inhibition, however, and I have found that camphor succeeds as well as anything. If a long horizontal glass tube with a mixture of camphor and phosphorus lying on the bottom is exhausted with an air pump, and air is allowed slowly to leak into it through a fine adjustment valve at one end, bright luminous flashes pass down the tube at short intervals. The camphor vapour holds up the combustion until enough air has leaked in to make a mixture of favourable composition, the combustion starts, and the wave is propagated. The period evidently depends on how strong is the inhibiting action. Ammonia is a convenient inhibitor for illustrating this, for its action may be made as powerful as is desired by using a more concentrated solution. The period of the flashes is increased accordingly. The moving clouds of luminosity observed when the absorption of oxygen by phosphorus is nearly complete, are thus linked up quite naturally with the existence of inhibiting substances.

Another series of experiments bring out a further unification of the same kind. They began with the repetition of an interesting observation by L. and E. Bloch, which showed that if some phosphorus was placed in a glass tube, it was possible to blow the glow away from it by a blast of air, and maintain it at a distance downstream. In this form the experiment is rather difficult of control, sometimes succeeding and sometimes failing, for no very apparent reason; but I found it ultimately to be a matter of temperature, a few degrees making the whole difference. Fig. 3 shows the arrangements made by me to bring this under satisfactory control. The phosphorus is a thin flat strip, cast into a suitable recess in the side of a water tank; thus its temperature cannot differ much from that of the water. The latter can be varied at pleasure by the use of ice or warm water. A flat sheet of glass is held at a distance of a millimetre or two parallel to the phosphorus slab, and the air flows between the two, being confined by suitable packing strips at the sides. The channel is prolonged downstream of the phosphorus, and is made suddenly deeper about two inches down.

The accompanying photographs (Fig. 4) illustrate the effects obtained. No. I shows how the phosphorus surface looks without any blast. V shows the glow blown right off, and maintaining itself downstream, where the channel is deepened. The dotted line (inked in on the photograph) shows the position of the phosphorus slab, which is quite dark. This is essentially the Blochs' original experiment. Interesting as it

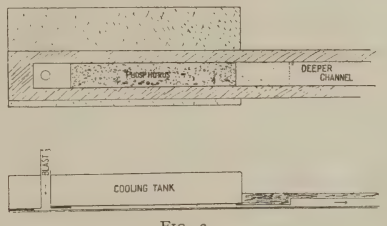

Fig. 3.

is, however, it by no means exhausts what we can learn with the arrangement described.

The effect of changes of temperature was examined, adjusting the blast in each case so that the glow was blown half-way down the phosphorus strip. The velocity of blast necessary to do this was found to diminish enormously as the temperature was reduced. Thus in cooling from room temperature to near the freezing-point, the velocity diminished a thousand times. I next tried altering the oxygen content, and

found to my astonishment that enriching the air with oxygen had the same effect as cooling, and diminished the necessary velocity of blast in an equally striking degree. In both these cases the ultimate result, when the velocity had been reduced to something of the order of 1 cm. per second, was to make the glow flickering and uncertain of maintenance. On cooling a little more, or adding a little more oxygen, it went out altogether.

Now we must remember a fact, often enough insisted upon nowadays, that motion is relative. We have thought so far of the blast acting on the stationary cloud of luminosity, but we might equally regard the cloud of luminosity as propagating itself in the reversed direction through still air. When the air is much enriched with oxygen the necessary blast is gentle—

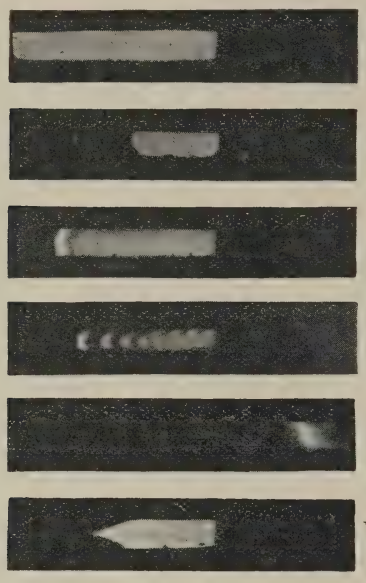

FIG. 4.

in other words, the propagation is slow. It appears then that *extinction is the limiting case of slow propagation*. If we can trace the cause of slow propagation the cause of extinction will not be far to seek.

Before passing to this, however, attention may be directed to some curious effects met with in the course of these experiments on the blast. The same sequence of changes occurs whether we reduce the temperature or increase the oxygen content. Suppose, for definiteness, that the latter course is followed. When the oxygen is very little, the glow tends to cling to particular spots, from which it cannot readily be detached. II shows this to some extent, though other experiments were made in which it was much more striking. On close examination it appeared that these special spots were depressions in the phosphorus surface, where there was partial shelter from the blast. At these places the glow started, and when once started, it infected the gas downstream of it, and made the blowing away impossible. VI shows this very clearly. In this case a hole was made intentionally.

As the oxygen content is increased a bright luminous head develops, followed by a darker space, and then uniform luminosity (III). This bright head no doubt represents the combustion of the stock of phosphorus vapour accumulated as the blast passes over the dar surface.

The next stage, IV, is observed when the blast is s rich in oxygen that extinction is near. A succession of bright heads separated by dark spaces has no developed. This photograph was given four hours exposure, and was not easily obtained: for some movement of the luminous heads is difficult to avoi during so long a time. The heads were seen quite regularly distributed along the column. The confusion on the right-hand side is due to unavoidable shifts.

The question arises as to why this propagation should occur at all, and why it should be slower when excess of oxygen is present. In the analogy of a train of gunpowder there is no doubt that propagation occurs primarily because each layer that has begun burning heats up the next layer, and causes it to burn too. In the case of phosphorus this explanation is scarcely tenable, because the phosphorus vapour present is only a very small fraction of the atmosphere in which it is contained, and it can be calculated that it cannot yield enough heat to raise the temperature more than a degree or two, which would not be enough.

We must look for some other way in which the action in one layer can help the action in the next; and the suggestion I make is that the action is of the kind called catalytic. It is true that this explanation is incomplete and in a measure speculative. On the other hand, it covers many facts otherwise very hard to co-ordinate. One of the most striking peculiarities of catalytic actions is the facility with which the catalyst is *poisoned*. The exact condition of a surface capable of producing this effect is a very critical thing, and I believe that when the glow of phosphorus is inhibited, it simply means that the particles of phosphoric oxide, or other product of combustion, are spoilt, or *poisoned* by the condensation of molecules of the inhibiting substances upon them; and that this prevents them from assisting the propagation. It is noteworthy that most of the inhibiting substances are easily condensable vapours, such as would be likely enough to act in this way. Oxygen is an exception, but it must be noticed, first, that oxygen will only act when moist; and, secondly, it has to be present in enormous excess—about 20,000 molecules of oxygen for one of phosphorus vapour—before it can quench the glow. Inhibitors like ammonia doubtless act by definite chemical union with phosphoric oxide.

Lastly, the view here explained requires us to suppose that the combination is always breaking out sporadically at isolated centres, though in the presence of an inhibitor it fails to propagate itself. I have recently been able to prove directly that this does in fact happen when oxygen is the inhibitor. When the gas-pressure was lowered the phosphorus glowed; but when it was raised again the phosphorus went out abruptly, like a candle blown out. Nevertheless, under the latter condition, it was found by observations lasting over several weeks, that a slow absorption was going on all the time, and that this action occurred between oxygen and the *vapour* of phosphorus.

This whole research has been rather off the main stream of scientific inquiry at the present time; but it shows that there is still a fascinating field for research about phenomena which have been familiar for centuries.

The Malaria Treatment of General Paralysis.

By Prof. WARRINGTON YORKE, M.D.

UNTIL recently the outlook for patients suffering from the disease known as general paralysis of the insane was practically hopeless. For many years, however, it has been known that the symptoms sometimes exhibited remarkable remissions, the delusions and other mental disturbances subsided or even disappeared for a time, whilst the physical condition underwent a similar improvement. It had been further observed that these remissions were often associated with some intercurrent disease, and attempts were made to induce them artificially by such measures as the production of abscesses or injection of bacterial toxins. The improvement was, however, only transient; sooner or later the mental symptoms reappeared, the patients returned to the asylum, and the disease pursued its relentless course to a fatal termination. In 1919 Wagner v. Jauregg of Vienna, as the result of many years' observation of general paralysis, concluded that possibly it was the rise of temperature, which accompanied the intercurrent disease, abscess formation, or vaccin inoculation, that was in some way responsible for the improvement produced in the nervous condition. With the view of testing this hypothesis, he set about to search round for an infection which could safely be administered to the patients and could, after it had run the necessary course, be readily controlled by the administration of drugs. Two diseases occurred to him, namely, malaria and relapsing fever; and after preliminary trials it was found that the former was the more satisfactory. Wagner v. Jauregg therefore proceeded to infect a long series of general paralytics with malaria, and during the years 1920–21 published results of a most promising nature.

It was the publication of these papers that induced L. Clark, the Medical Superintendent of the County Mental Hospital at Whittingham, to test the treatment at his institution; and in July 1922 a number of general paralytics were infected by inoculation of blood from patients who had contracted malaria in the tropics and had come to the hospital of the Liverpool School of Tropical Medicine for treatment. These general paralytics in due course developed typical malaria, and from them other paralytics were inoculated, and so on, the malaria strain being preserved by regular passage from one paralytic to another. Later, the work was commenced at the other mental hospitals of the neighbourhoods, namely, Rainhill, Winwick, Ilfast, and Chester.

For various reasons it was decided in a number of instances to modify the mode of infecting the patient, and, instead of producing the disease by the inoculation of malaria blood, to do so by Nature's method; *i.e.* by the bite of infective mosquitoes. The mosquitoes used were two commonly found in Great Britain, namely, *Anopheles maculipennis* and *Anopheles bifurcatus*, and for a constant supply of the former we are greatly indebted to Mr. Rees Wright, of the Department of Zoology, University College, Bangor, who during the winter collected the hibernating females in farm buildings in Carnarvonshire.

Up to April 1924, at the various institutions mentioned and at the Royal Infirmary in Liverpool, 139 cases of general paralysis had been infected with malaria, 98 by the method of direct inoculation of infective blood withdrawn from malaria patients, and 41 by the bites of infective Anopheles. A sufficient time has now elapsed to enable a judgment to be formed regarding the effect of the malaria treatment in respect of 84 of these patients. Summarising the opinion of the medical experts at the mental hospitals, we find that of the 84 patients, fourteen (16·6 per cent.) have died, most of them immediately, or shortly after the completion of the course of malaria treatment; although all these cases had been treated with quinine before death, and parasites had disappeared from the blood, nevertheless it is impossible to affirm that in none of them was death accelerated by the malaria. No noticeable change in mental or physical condition has been observed in twenty (23·8 per cent.); with regard to these cases, however, it is to be borne in mind, as the mental hospital doctors have frequently pointed out, that in the ordinary course of events many of them would now be dead. In ten (11·9 per cent.) there is definite physical improvement but no change in the mental condition. In seventeen (20·2 per cent.) there is great physical and distinct mental improvement. Finally, in twenty-three (27·4 per cent.) the mental and physical improvement has been so great that the patients have been, or are about to be, discharged from the mental hospitals.

It is to be noted that in a number of the cases the improvement has been maintained for many months —in some for so long as a year—and that quite a number are back at their old occupations. As time goes on, it may be found possible to discharge still others of these 84 cases, for, as Wagner v. Jauregg writes: "The maximum of the improvement does not manifest itself at once at the end of the period of fever, but does later. On the contrary, the improvement continues often for a long period, so that in many cases the result seemed to be an incomplete one where later, however, a complete remission came to pass."

Whether the improvement is temporary or permanent, time alone can decide, but the results already achieved can only be regarded as remarkable, when it is realised that no patient suffering from general paralysis had previously been discharged from the mental hospitals in question.

A number of hypotheses have been advanced to explain the mechanism whereby the one disease produces a beneficial action on the other disease; but as none of these hypotheses are based on any substantial foundation, nothing is to be gained by discussing them here.

As might be expected, work of this nature has enabled us to observe malaria in exceptionally favourable circumstances, and as a consequence much has been learned regarding this disease, and many hitherto unsolved problems have been answered. From this point of view the natural infections, *i.e.* those produced by the bites of infective Anopheline mosquitoes, have been especially valuable. They have enabled us to prove beyond all doubt that the three common malaria parasites are all true species and not merely different

stages of the same parasite, as has been so long maintained by Laveran and numerous other observers of the French school. The incubation period of simple tertian malaria — that is, the period which elapses between the bite of an infective mosquito and the development of symptoms and the appearance of parasites in the peripheral blood—has been shown to vary between 9 and 22 days; and much has been learned regarding the clinical course of the disease.

In striking contrast to the cases of malaria which occurred in such enormous numbers during the War, and those with which one has to deal in the ordinary practice of tropical medicine, the general paralytics were readily cured of their induced malaria by a three-days course of quinine, and relapses were remarkably rare. Why this should be so is a question of no mere academic interest, but one of great practical importance and one to which my colleague, Dr. Scott Macfie, and I devoted much thought and work. As the result of a most careful analysis of all the facts available, the conclusion was reached that the remarkable susceptibility to treatment exhibited by the cases of induced malaria is bound up with the fact that in these cases one is concerned with the early treatment of the disease, or, in other words, with the treatment of primary infections.

In our opinion the train of events in the treatment of malaria is as follows: quinine given to a patient whose blood contains numerous malaria parasites invariably destroys—probably indirectly, *i.e.* after it has been changed in some manner by the human body—large numbers, but not all, of the parasites, and by this means sets free a considerable quantity of soluble antigen. The antigen provokes, by stimulation of the host's tissues, the formation of immune-body. The immune-body, if sufficient in amount, destroys the remaining parasites, thus resulting in sterilisation of the infection and in the cure of the patient. When, for any reason, the host is unable to produce immune-body in sufficient amount, the infection is not sterilised and a relapse occurs. We surmise that certain individuals are unable to produce a sufficiency of immune-body to sterilise the malaria infection, possibly owing to inadequate treatment at the time of the fir attack, possibly owing to ill-health at the time infection and treatment, or possibly owing to a person idiosyncrasy. Whatever be the cause, these are t patients who develop into chronic relapse cases malaria; such patients can no longer be cured b quinine, not because the parasites they harbour a quinine resistant, but because, owing to a defecti formation of immune-body at the time of the initi attack and treatment, the parasites have not bee completely destroyed and have gradually acquired a immune-body resistance. If this view be correct, indicates the paramount importance of adequate quinin treatment at the time of the initial attack of malaria a course of treatment which suffices to sterilise th primary malaria infection fails to prevent the occu rence of relapses when administered to a case of som standing, and this explains the complete lack of succes which followed the most drastic efforts to sterilise th infection in the patients invalided with malaria t Great Britain during the War.

Whether the daily taking of quinine will protect fro malaria those living in the Tropics, and subject to th bites of infected mosquitoes, is naturally a questio of the greatest importance. Notwithstanding th enormous literature bearing on the subject, no precis information has hitherto been obtained, mainly owin to the great practical difficulties which surround an attempt to make observations from which it would b possible to draw conclusions free from very obviou fallacies. The present investigation has, howeve provided the answer to this important question. Ou observations showed that the administration of quinin before a person is bitten by an infected mosquito i useless, and that the drug has little if any action o the sporozoites injected by the mosquito. In order t prevent the malaria from developing, the administra tion of the drug must be continued for at least te days after the feed of the infective mosquitoes; th daily dose of quinine given has but little influence apar from the fact that, with very large doses (30 grains), th period for which the drug has to be given to preven development of the infection is a little shortened.

Obituary.

Dr. W. B. Hemsley, F.R.S.

WILLIAM BOTTING HEMSLEY, whose death, in his eighty-first year, took place at Broadstairs on October 7, was born at East Hoathly, Sussex, on December 29, 1843. A member of a family which had a long and honourable connexion with horticulture, Hemsley's knowledge of plants began with his knowledge of the alphabet. Being a somewhat delicate child he had to be educated privately, and before his education had been completed, in order to lead, so far as possible, an out-of-door life, he began his training as a gardener in his father's establishment. Already his taste for botanical pursuits was so marked that, as soon as his training had been completed, he entered Kew as a young gardener in 1860, when in his seventeenth year.

Before the period of two years to which the service of a young gardener at Kew is normally limited, Hemsley's remarkable botanical aptitude had so impressed both the Curator and the Director that h was transferred from the garden to the herbarium Here young Hemsley's capacity attracted the attentio of Mr. G. Bentham, who was then at work on his grea "Flora Australiensis," in the preface to the firs volume of which reference is made to Hemsley' services. While a temporary technical assistant i the herbarium, Hemsley gave all his spare time t general botanical studies; in 1863 he gained a firs prize in botany, awarded by the Royal Society of Arts In 1865 a vacancy occurred in the permanent her barium staff, and Hemsley was selected to fill it. Bu Hemsley's physique could not stand the strain to which the enthusiasm and assiduity with which he performed the duties of Herbarium Clerk subjected it. In 1867 a complete breakdown in health compelled Hemsley, to the regret of his superior officers, to relinquish his clerkship and retire to Sussex. Here, in spite of his illness, Hemsley devoted himself to mastering Latin,

Linnean, and French, and continued his botanical pursuits, the results of which were embodied in a "Handbook of Hardy Trees, Shrubs and Herbaceous Plants," still highly esteemed by gardeners, and in an "Outline of the Flora of Sussex," prized by local botanists. So high was the standard Hemsley had set himself and had attained, that in 1875 the Linnean Society elected him one of its botanical associates.

By 1874, Hemsley's health, though still indifferent, justified his return to Kew as an independent worker. During the next nine years he was engaged principally on the task of elaborating the phanerogamic material obtained during the cruise of the *Challenger*, and of describing the botanical collections of Messrs. Salvin and Godman. The *Challenger* report was published in 1885, and secured for Hemsley the position of a recognised authority on insular floras. The botanical work done on behalf of Salvin and Godman was published in the five botanical volumes of their great "Biologia Centrali-Americana," issued at intervals during 1879–1888; the extraordinary value of this Mexican flora was recognised, so soon as it was completed, by Hemsley's election to the Royal Society in 1889.

Meanwhile Hemsley's health had, happily, become completely restored, and in 1883 he once more was able to join the permanent staff of the herbarium at Kew as assistant for India. In 1890, when Prof. D. Oliver was succeeded by Mr. J. G. Baker as Keeper of the Herbarium and Library, Hemsley was appointed a principal assistant in succession to Mr. Baker, and in 1899, when the latter retired from the public service, Hemsley again succeeded Baker, and served as Keeper of the Herbarium and Library at Kew until his own retirement, at sixty-five, on December 28, 1908. While assistant for India and principal assistant, Hemsley was able to prepare his invaluable work on the flora of China, which occupies three entire volumes of the Linnean Society's Journal. During this period, too, he collaborated with Dr. J. E. T. Aitchison in working out the botanical results of the Afghan Boundary Commission, with Sir Henry Collett in doing the same for the Shan Plateau, and with Mr. H. H. W. Pearson in writing a valuable "Flora of High Asia." He was also the author of many smaller, but always important, botanical contributions, mainly of a systematic character. He took a share, with other members of the Kew staff, in the preparation of the "Flora of Tropical Africa," and assisted Sir Joseph Hooker, after his retirement in 1885, in connexion with the *Botanical Magazine*, which Sir Joseph continued to edit after he had ceased to be Director of Kew.

As Keeper of the Herbarium, Hemsley found his time very fully occupied with official duties, and although many minor contributions to botanical literature were still made by him, he wisely avoided undertaking any task so formidable as those accomplished in his earlier years of active work. After his retirement Hemsley continued this policy for another reason. He did not care to undertake a task he might not have strength to complete. His work on the matters he took up remained, however, as excellent as ever, and was continued until failing physical powers necessitated his seeking a home in a climate more bracing than that of the Thames Valley.

Hemsley's labours were appreciated as highly in other countries as in his own. His contribution to the "Biologia Centrali-Americana" brought him honorary membership of the Natural History Society of Mexico; his knowledge of insular floras brought him honorary membership of the Royal Society of New South Wales, and of the New Zealand Institute, and corresponding membership of the German Botanical Society. His services to garden-lovers brought him honorary membership of the Royal Horticultural Society and the award of its Victoria Medal of Honour. In 1896 the Linnean Society accorded him, at his own request, transfer from associateship to fellowship, and in 1918 the University of Aberdeen conferred on him the honorary degree of LL.D.

The courtesy and consideration which made collaboration with Hemsley as a botanical author as pleasant as it was profitable to those thus privileged, made the relationship between himself as Keeper and his colleagues in the Herbarium equally cordial. Not they alone, but all who ever came in contact with Hemsley will treasure the memory of one whom they esteemed for a kindness as genuine as his sincerity, for a knowledge as remarkable as his modesty.

Lord Abercromby.

Archæological circles in Scotland have lost one of their most distinguished figures by the death of Lord Abercromby, which took place at Edinburgh on October 7 in his eighty-third year.

John, fifth baron Abercromby of Aboukir and Tullibody, was born on January 15, 1841. He was a great-grandson of General Sir Ralph Abercromby, who died from wounds at the battle of Alexandria in 1801, and whose widow was created a baroness. Lord Abercromby succeeded to the title on the death of his brother in 1917. He was educated at Harrow, and for some years held a commission in the Rifle Brigade. After his retirement he took up the study of philology, folklore, and archæology. His publications were not numerous, but they were characterised by accuracy, scholarship, and judgment. Although not all of his conclusions have found acceptance, some of his views, especially those relating to the origin and distribution of Bronze Age types of pottery, have had a profound and widespread influence on the trend of archæological thought. One of the earliest of his publications was "A Trip through the Eastern Caucasus." Better known was his "Pre- and Proto-Historic Finns," in which he traced the history of the Eastern and Western Finns from neolithic times to the Middle Ages, analysed their religious beliefs and folklore, and translated their traditional magic songs. This valuable piece of work was recognised by election as an honorary member of the Finnish Archæological Society and the Finno-Ougrian Society of Helsingfors. His most important work, however, was his "Bronze Age Pottery of Great Britain and Ireland," which appeared in 1912; this was a gathering together and elaboration of the views which he had expressed in various scientific periodicals in the preceding ten years or more. A further notable contribution to the study of prehistoric ceramics appeared in the Journal of the Royal Anthropological Institute for 1914 under the title "The Prehistoric Pottery of the Canary Islands and its Makers."

Lord Abercromby was a fellow of the Royal Society of Edinburgh and an hon. LL.D. of the University of Edinburgh. He was a vice-president of the Folk-lore Society and formerly president of the Society of Antiquaries of Scotland. In 1921 he presided over Section H (Anthropology) of the British Association at the Edinburgh meeting, and when, in the following year, a local branch of the Royal Anthropological Institute was formed at Edinburgh, he was unanimously elected the first president. His tact and charm of manner, his never-failing courtesy to all, and his assiduous attention to the duties of the offices he held, notwithstanding failing health, won the affection and respect of all with whom he came into contact. As Lord Abercromby leaves no heirs male, the title now becomes extinct.

THE death is announced on August 4 last of Dr. Santiago Roth, head of the department of palæontology in the Museum of La Plata, Argentina. Dr. Roth was born in Switzerland and emigrated to Argentina nearly half a century ago, where he became especially skilled in collecting fossil skeletons of mammals from the pampas. He sold many fine specimens to the museums of Zurich and Geneva, and some also to the Zoological Museum of Copenhagen. When the Museu of La Plata was founded, he was employed by the la Dr. F. P. Moreno to collect similar pampean skeleto for that institution, and he was soon appointed to tal charge of the fossils. Dr. Roth added much to o knowledge of the pampean formations, which l studied extensively and in great detail, and he al described many of the mammalian remains.

WE regret to announce the following deaths:

Dr. Edouard G. Deville, I.S.O., Director-General Surveys in the Canadian Department of the Interio and author of "Astronomic and Geodetic Calcul tions" and "Photographic Surveying," on Septemb 21, aged seventy-three.

Dr. E. O. Hovey, curator of the Department Geology and Invertebrate Paleontology of th American Museum of Natural History, on Septembe 27, from a stroke received in his office on the pr ceding day, aged sixty-two.

Dr. C. W. Moulton, professor of chemistry sinc 1894 at Vassar College, New York, on September 1 aged sixty-five.

Dr. J. M. Schaeberle, formerly at the Lick Observa tory, and author of a number of papers on astr nomical subjects, aged seventy-one.

Current Topics and Events

THE Everest Expedition of 1924 reported to a joint meeting of the Royal Geographical Society and the Alpine Club before a distinguished assembly in the Albert Hall on October 17. Earlier in the day a memorial service for Mallory and Irvine was held in St. Paul's Cathedral. Pioneers like Drake and Livingstone, these two perished, as did Scott and Shackleton, in an attempt to go one step beyond the bounds hitherto set to human endeavour, and their names in their simplest form will be treasured in the national memory. Both were Cheshire men, and the Bishop of Chester embodied the spirit of the impressive service under the famous Cathedral dome in an address which showed how the two mountaineers, now at rest in the most magnificent cenotaph in the world, were great climbers because they were great men full of courage, unselfishness and cheerfulness, men who had attained to great spiritual heights, men who had risked life itself in the service of others. Odell, who was in support, was climbing to Camp VI. on June 8 by a circuitous route. He discovered fossils in a band of limestone, and found himself enveloped in mist with clear sky above. By a mere chance he climbed a crag and emerged into a sudden temporary clearing of the mist to a vision of the summit ridge and peak of Everest. Far away on a snow slope near the base of the final pyramid he saw two figures climbing slowly towards their goal, one reaching out to help the other, then the mist fell again. The time was 12.50, and Mallory and Irvine were three hours late on their time schedule, yet they were pressing on. The chances are that they were speeding to the accomplishment of the little bit more which meant so much. Odell believes they got to the summit and were benighted on th return journey. *Sic itur ad astra*. The sure recor stands that Mallory and Irvine climbed to 28,23 feet with the help of oxygen. On another attempt Norton and Somervell reached 28,130 feet withou oxygen, and this presages a future success by similar effort which will probably be made in 192 Other records were Odell's three ascents betwee 25,000 and 27,000 feet within a week, the carriag by six porters of loads to a height of 27,000 feet men have slept well in camp at 26,800 feet. Th upper half of Everest consists of slabby altered lime stones, a 1000-feet thickness of sandstone and fossil has been found, and in 1924 persistent cold wind blew from the west with night temperatures whic fell once to −22° F. At Camp IV., 23,000 feet twice in June, the noon sun temperature was 105° F. while the air temperature was only 29° F.

THE broadcasting last week of the speeches of th leading politicians of Great Britain proves that th influence of radio communication on the lives an affairs of men is already very great. Mr. Reith, th manager of the British Broadcasting Company, i an article in the October *Quarterly Review*, gives a account of the present position of the art and indicate some possible future developments. In less than two years the staff has increased from 4 to 350, and operations are now carried out nightly in twenty cities. A system of simultaneous broadcasting has been carried out for more than a year, and practically a million licenses have been issued. There are very few "blind spots," that is, regions which suffer appreciably from shielding, due possibly to hills,

ire reception is in consequence difficult. In the ightly audience every grade of society, every t dard of intellectual attainment, and every variety f aste are represented. The managers aim at giving sa sfaction to three-quarters of the audience, three- rters of the time. Their aim is both entertain- nt and instruction, and the educational possi- ilies are being rapidly developed. By the aid of h master microphone a single man can influence a ti on, and through its agency the ideals of universal br herhood can be broadcast over the whole world. At the present moment, by means of the cheapest rstal set, about 75 per cent. of the total population of Great Britain can listen in. A large fraction of h remaining 25 per cent. will be covered when the ni power station thirty miles north of London is opned next year. This station has a guaranteed ge of 100 miles for cheap crystal sets, 300 for gle-valve sets, and about 1000 for two-valve sets. Th Bethnal Green Borough Council recently ggested that they should erect a central aerial to sp ply the district, and so dispense with the necessity fo independent aerials in every house. We think th t the suggestion is impracticable, while the legality of such a proceeding is open to question; but many o the unsightly and unnecessary aerials hung out by tenants should be prohibited by law. The situation ight be improved if radio manufacturers would advertise more largely the fact that in most cases, wen electric or gas lighting is used, an aerial is unecessary even with crystal sets.

Sir Arthur Evans, in the *Times* of October 16 and 17, gives a further account of his work in Crete during the present year. Investigations of the neo- lithic remains immediately below the Central Court have brought to light three fragments of stone vessels to be related to the early Nilotic lapidary work. They are the first to be found in pure late neolithic floor deposits. Vessels of predynastic form and material had already been found at Knossos, but in unstratified earth. This discovery throws back the actual contact between Crete and Egypt and the closing phase of neolithic culture in the island to the middle of the fourth millennium B.C. The road from Knossos to the south coast has now been traced to a Minoan haven at Como round a headland north of the harbour of Matala. Excavation of the in- durated clay at the point where this road abuts on the hillside below Knossos has revealed further details of the construction of the viaduct across the ravine and the entrance system of the palace, as well as the pavilion or caravanserai at the south-eastern extremity of the viaduct. This building of unique character faces north with a frontage of more than 50 feet. The walls of the pavilion, only the lower parts of which are standing, had been covered with frescoes, of which fragments preserved in the petrified ground have been pieced together and reveal a frieze of a novel character of naturalistic red-legged partridges and hoopoes on a highly conventionalised landscape background. The bath chamber adjacent had an elaborate system of conduit pipes. In an underground "fountain" chamber packed with votive vessels was found a primitive image of a goddess within a vessel shaped like a round hut—the Lady of the Source herself.

The work of Prof. A. Maihle, of the University of Toulouse, on the catalytic effect of various contact materials on a great variety of materials, is well known to the organic chemist, but recent develop- ments, from the point of view of the supply of fuel for internal combustion engines, have attracted considerable attention amongst fuel technologists. At a recent congress held in Paris, Maihle described his work on the pyrogenesis of fatty oils and showed how a copper-aluminium catalyst brought about the rearrangement of linseed oil into a synthetic petroleum. The fatty acid from arachin oil brought into contact with tested magnesium chloride yielded 68 per cent. of a "mineral" oil which contained motor spirit, burning oil, and more viscous components. A similar product was obtainable from chlorophyll, and it appears possible that even cellulose would be capable of yielding hydrocarbons. At the same time, it should be mentioned that the commercial possibilities of this work are probably highly over- estimated. Up to the present date, less than one cubic mile of petroleum has been extracted from the earth's crust, and the world is faced to-day with over-production rather than with a deficit of mineral oil. Even when the known resources of petroleum are exhausted, there are untold volumes of potential liquid fuel derivable from shale, whilst the work of Bergius indicates that even when shales are exhausted, every coalfield is a nascent oil reservoir. In these circumstances it is difficult to see that the production of oil from vegetable sources is other than of scientific interest.

A series of short instructions on the method of taking and reporting readings of temperature and rainfall has been issued by the Meteorological Office, Air Ministry. The pamphlet bears the title of "The Observer's Primer" and was primarily prepared for meteorological observers in British Crown Colonies. The instructions, if carefully considered by observers of the weather, will render the observations made of much greater value. Uniformity of system in observing is of primary importance, and careful readings of temperature and rainfall are of infinitely more value than minuteness in the fineness of reading. Instructions are given as to the exposure of thermo- meters and the position of the rain-gauge. The hints are essentially of value to new observers, and if followed will place the observer on the same footing as one who has already had experience.

Monthly normals of rainfall for the British Isles for periods ending 1915 have recently been published as Section V. of "The Book of Normals" by the Meteorological Office of the Air Ministry. The material has been prepared by the British Rainfall Organisation, which, since 1919, has been incor- porated in the Meteorological Office. Monthly and annual values are given for 578 widely distributed places, compiled from the records for the 35 years

1881 to 1915. This period is chosen chiefly because it probably gives the largest number of synchronous and homogeneous records. Section V. covers the same ground as Section I., but it comprises many more stations; the additional information now available has been utilised for the present issue and where necessary corrections have been made. The arrangement of the stations is the same as that adopted in "British Rainfall" and differs from that of previous sections of "The Book of Normals." It is now easy for any inquirer to compare the very different amounts of rain which occur in different places. The modifications made in Section V. are fairly numerous, as is clearly seen from a careful examination. It is of general interest to see how on the same coast the average rainfall differs; at Eastbourne the total for the year is more than 3 inches heavier than at Worthing, and an excess is maintained in every month of the year. The mean for the 35 years at Greenwich Observatory is about 1 inch less than the mean for 100 years terminating at the same date; for the 35 years the mean for September is 0·47 inch less than December, while for the 100 years, September is wetter than December.

Two hundred years ago this month, the firm now known as Longmans, Green and Co., publishers, was founded by Thomas Longman, an ancestor of some of the present directors, and we are sure that our readers everywhere will join us in offering our congratulations on the completion of so long a period of public service. Thomas Longman was apprenticed to a bookseller in Lombard Street in 1716, and when his indentures ran out in 1724, he acquired the business of a publisher and bookseller in Paternoster Row at the sign of the Ship in Full Sail. That site marks the birthplace of the house of Longman, and it is interesting to note that, with the exception of a short period, 1861–63, when a fire made rebuilding necessary, a publishing business in the name of Longman has occupied the site continuously for two centuries, while the old sign has been adopted as the firm's trademark. From the date of its foundation onward, at least one Longman has been in the firm, and now the sixth generation is in possession. It is a fine example of the inheritance and development of traditions which have led to an important and ever-increasing business. Among the works issued by Longmans with which scientific workers will be familiar are Salmon's "Conic Sections," Herbert Spencer's "Principles of Psychology," Herschel's "Outlines of Astronomy," Webb's "Celestial Objects," and Gray's "Anatomy," which was published in 1858 and achieved its twenty-second edition last year. Then in the 'sixties came Tyndall's Lectures, while of more modern works we may quote Watt's "Dictionary of Chemistry," Sir Edward Thorpe's "Dictionary of Applied Chemistry," Mellor's "Inorganic and Organic Chemistry," which is now in course of publication, J. G. Millais' sumptuous volumes on British ducks and on rhododendrons, and Thorburn's equally beautiful works on British birds and mammals. The firm and its directors have a record of which they may well be proud, and we wish them long and continued prosperity.

THE seventh annual Streatfeild Memorial Lectu will be delivered at 4 o'clock on Thursday, Novemb 6, at the Finsbury Technical College, Leonard Stre E.C.2, by Mr. Julian L. Baker, who will speak " The Chemist and the Fermentation Industries."

THE Thomas Hawksley lecture of the Institutio of Mechanical Engineers will be delivered at t institution at 6 o'clock on Friday, November 7, b Vice-Admiral Sir George G. Goodwin. The subje will be "The Trend of Development of Mari Propelling Machinery."

THE British Association for the Woollen an Worsted Industries is inviting applications fro persons who have engaged in original research for th post of physicist. Applications stating academ qualifications, research work, and technical or engi eering experience, if any, should be sent to the Secr tary of the Association, Torridon, Headingley, Leed

APPLICATIONS are invited from holders of university honours degree in science or engineerin or equivalent, with experience in engineering work for a research assistantship at the Royal Aircra establishment, South Farnborough, Hants, for wor in connexion with aero engines. The application quoting reference No. 37, should be sent to th superintendent of the establishment.

THE Dorset Field Club announces that the Cec Medal and Prize of 10*l.* will be awarded in May nex for the best essay on "Broadcasting: its Possibilitie and Limitations." The competition is open t persons between the ages of seventeen and thirty-five born in Dorset or resident in that county for not les than a year between May 1, 1923 and 1925. Particu lars of the competition are obtainable from Mr. H Pouncy, Midland Bank Chambers, Dorchester.

A REPRESENTATIVE assembly was present at th memorial service for the late Sir William Herdma at the ancient chapel of Toxteth in Liverpool, o Thursday, October 16. The Mayors of Liverpoo and Birkenhead, representatives of the University the various civic bodies, the Royal Society, th British Association, the Marine Biological Association the Liverpool School of Tropical Medicine, the Society of Chemical Industry, and other institutions attended The Unitarian service was conducted by the Rev C. M. Wright, the minister of the chapel.

IN addition to the development of commercia transport by rigid airship, the directors of civi aviation in the United States of America have a programme of semi-rigid airship construction and operation. The latter have the advantage of smaller size, first cost and running expenses, but have less speed, range and carrying capacity, and less ability to ride out a spell of bad weather. Available data are so untrustworthy that it is better to await the completion of the programme rather than to offer anticipations which can be little better than guesses.

THE following committee has been appointed by the Board of Trade to consider and report on the steps which can be taken to bring about the growing

of flax seed and flax in the British Isles on a commercial scale :—Sir Frank Warner (chairman), Mr. Norman Boase, Mr. J. G. Crawford, Sir A. Daniel and Mr. A. L. Hetherington, Sir Thomas H. Middleton and Mr. H. Mead Taylor, together with a representative, to be appointed later, of the Ministry of Commerce of Northern Ireland. The Secretary to the committee, to whom all communications should be addressed, is Capt. S. E. J. Brady, Board of Trade, Great George Street, London, S.W.1.

THE Council of the Institution of Automobile Engineers has made the following awards for papers read during the past session :—Crompton Medal to Dr. Aitchison for his paper entitled "Light Alloys for Pistons and Connecting-Rods," the Utility Prize, given by Col. D. J. Smith for the paper of greatest utility to the automobile industry, also to Dr. Aitchison for the same paper; Graduates Prize to Mr. R. N. Aveline (Coventry Branch) for his paper entitled "Carburation."

IN the Report on the Raffles Museum, Singapore, for 1923, Mr. C. Boden Kloss, who has succeeded Major J. C. Moulton as director, announces that a portion has been given for a new wing on the site recently vacant for this purpose between the museum and the sea. The museum is becoming yet more frequently used by local residents who seek information from a scientific or commercial point of view. From near the summit of Gunong Angsi (2700 ft.), in Negri Sembilan, Mr. F. N. Chasen has obtained a specimen of a martin, *Chelidon dasypus*, the first one recorded from the mainland of the Malay Peninsula.

THE September issue of the Journal of the Franklin Institute gives an account of the presentation on May 21 of the Franklin medals to Sir E. Rutherford and Dr. E. Weston respectively. Unfortunately neither recipient could be present in person, but the former sent an interesting account of the events and ideas that guided him in his early researches in radioactivity, which was read by Dr. J. S. Ames, professor of physics in the Johns Hopkins University. Dr Weston is well known as the inventor of the standard cell, but it is not generally known that he discovered and patented the resistance alloy now known as manganin, the manufacture of which was taken up in Germany. Dr. Weston was born in England in 1850 and went to America in 1870.

THE Technological Museum of Sydney has so high a reputation in Great Britain that it is disappointing to read in its latest annual report that "it has not received that appreciation of the public such an institution deserves." Since the attendance for the year was 43,138, since visits to the museum form part of the work of the elder scholars in the Secondary and High Schools, and since many manufacturers have generously augmented the industrial exhibits, we infer that the director is alluding only to the inadequacy of the State grant. The annual vote, which had been temporarily suspended, has indeed been restored, but the available money is not enough to meet the needs of the central museum and of the six country branches. Let us hope that, as the situation improves, the claims of this admirable institution may meet with due recognition.

IN the October number of *Scribner's Magazine* is an article on predicting earthquakes by Prof. T. A. Jaggar of the Hawaiian Volcano Observatory. Though he refers to one or two successful forecasts of volcanic eruptions, the article is rather a plea for the foundation of a geophysical observatory in New York, a plea supported by an account of an imaginary earthquake in that city in 1932. There is no reason, he considers, for regarding New York or Washington as immune from a shock like that of Charleston in 1886. Prof. Jaggar's view is partly due to a table of seismicity which he has compiled for various regions, depending on the number of earthquakes per year for an average square mile without regard to their intensity. In the eighth degree, he places New York and New England with central California and parts of New Zealand and Mexico. But, in the ninth degree, are included the north of England along with Asia Minor, Messina, and the Lesser Antilles; and, in the tenth and highest degree, Perthshire beside Manila, Guatemala, and Tokyo.

AT the opening meeting for the 1924–25 session of the Institution of Petroleum Technologists, held on October 7, awards of the Institution's medals and scholarships were announced. The Boverton Redwood Medal for the sessions 1919–20 and 1920–21 was awarded to M. Paul de Chambrier of Pechelbronn, for his paper on the "Working of Petroleum by means of 'Shafts' and 'Galleries,'" read before the Institution on February 15, 1921. This medal, presented to the Institution by Mr. Alexander Duckham to commemorate the late Sir Boverton Redwood, founder and first president of the Institution, is awarded to the author of the paper of the greatest merit on any subject connected with petroleum technology, presented to the Institution during two consecutive sessions, and is not confined to members of the Institution. The award has been made retrospective to 1919, the date of Sir Boverton Redwood's death. As there was no paper of outstanding merit for the sessions 1921–22 and 1922–23, no award has been made for those sessions. The Student's Medal and Prize has been awarded to Lieut. J. H. Blakiston, R.N.R., formerly student of the oil technology course at the University of Birmingham, for his paper entitled "The Oilfields of Roumania." This award is made to the student member of the Institution who presents the best paper on any subject connected with petroleum technology, in any one session. This is the first award of this medal and prize. A Scholarship has been awarded to Mr. Ernest Clark, of the Royal School of Mines. These scholarships are awarded annually, one each to the Royal School of Mines, Imperial College of Science and Technology, London, and to the University of Birmingham, to a third year student, taking the petroleum technology course, who is also a student member of the Institution.

A LARGE part of the Report of the South African Museum for 1923 is taken up by the late Dr.

Peringuey's complaint of the delay in providing additional buildings. The large whale skeletons that stood so long in the open—to their considerable detriment—have been covered by a T-shaped building of brick with asbestos roof; but for some reason this was not made large enough to include a fin-whale and a male sperm-whale. Counting these, all the cetaceans known to occur along the coast of the Union are represented, except two porpoises. Special mention is made of *Balænoptera rostrata* and *Neobalæna marginata*, which have not long been known to occur in these waters. Owing to the damaged condition of many skeletons, some new ones are required, but so far only one whaling company, and that a foreign one, has befriended the museum. An old iron and wood building was obtained to store some of the other vertebrate skeletons, and, pending the erection of a wing for which 20,000*l*. was voted in 1914, this has also been used for exhibition purposes. One of the wings of the main building has been lent to the Art Gallery, which also waits in vain for the completion of a promised building. Whatever be the cause, it is certainly regrettable that valuable collections should be suffered to decay for lack of halls and cases.

LAST year at about this time we were able to extend a welcome to the *British Journal of Experimental Biology*, which was the first periodical in Gr Britain designed to cover this important and growi field. Other countries were already served by co parable publications. We now learn that an int national journal of general biology, under the title *Biologia Generalis*, is to be issued shortly under t editorship of Prof. Leopold Löhner, of the Universi of Graz, Prof. Raymond Pearl, of the Johns Hopki University, Baltimore, and Prof. Vladislav Ruzič of the Charles' University, Prague. The list of editors, who will presumably form an editing co mittee, contains the names of biologists from m European countries and also from the United Stat of America. It is proposed to publish origin articles on general morphology, physiology, a ecology, and contributions will be printed in Englis French, German, Italian, or Russian. The pu lishers of the new journal are Messrs. Emil Haim a Co., Vienna 1, Maria Theresienstrasse 10, and Bra slave, C.S.R., or, in the United States, through t Johns Hopkins Press.

MR. H. KIRKE SWANN is publishing, throu Messrs. Wheldon and Wesley, Ltd., in 12 parts, limited edition of "A Monograph of the Birds Prey (Order Accipitres)." The work will be illu strated in colour by H. Gronvold, and the first part promised for November 15.

Our Astronomical Column.

THE ASTRONOMICAL DAY.—In a recent notice in this column of the Brussels Annuaire, it was stated, on the authority of the Annuaire, that the "Berliner Jahrbuch" for 1925 was not participating in the change of the commencement of the astronomical day from noon to midnight. Examination of next year's issue of the Jahrbuch shows that this statement is incorrect; that publication comes into line with all the other national ephemerides, which is a matter of congratulation, as a variety of usage in different countries would be a source of frequent errors. It is not too early to remind astronomers to make the change in any publications relating to next year's work. In a few cases it has been overlooked.

THE STARS OF TYPE O.—An important monograph on these stars by Dr. J. S. Plaskett forms vol. ii., No. 16, of the Publications of the Dominion Astrophysical Observatory. They are the most massive of any type; their mean mass is shown to be some 45 times that of the sun, the probable range being from 10 to 80 times that mass. The mean mass for early B stars (Bo to B5) is 10 times that of the sun.

In spite of the high mass, the O stars have the high average radial velocity (cleared of sun's velocity) of 25·5 km./sec., which is higher than that of any type except the M variables (35 km./sec.). The total space velocity is twice as great.

The close relationship between O stars and planetary nebulæ has been indicated before, but is further demonstrated.

The mean parallax of the O stars is difficult to determine, owing to their small proper motions. It is found to be about 0·0011″ for 6th magnitude stars, indicating a distance of 3000 light-years and an absolute magnitude of $-4^{mag.}$, which agrees with Eddington's mass luminosity relation.

The monograph proceeds to discuss the fix H, K calcium lines, supposed to indicate cosm clouds between the earth and the stars, excited their radiation. The Wolf-Rayet or "Emission O stars are also discussed. Dr. Plaskett adopts t notation of O5 to O9 for the Harvard Oa to Oe. H proposes that the suffix *e* should be used to deno the presence of emission lines.

Many of the spectra discussed are reproduced three plates at the end of the work.

STELLAR DISTRIBUTION.—The researches of M K. G. Malmquist on this subject were recently note in this column. The question of the relative frequenc of the different spectral types, and of the giants a dwarfs of the same type, is of such fundament importance in stellar cosmogony that it is of intere to give for comparison the figures given by Pro Harlow Shapley (*Scientific Monthly*, May 1924) f the numbers of stars of different types contained i a cube the side of which is 100 parsecs; they a Giant M 22, Giant K 160, Giant B 4·4, Giant A 25 Dwarf F 680, Dwarf G (solar type) 7600. He note that Dwarf K and M would far outnumber the las but exact data are not available. He conclud from the small figure for Giant B that extremel few stars have sufficient mass to attain so high temperature. It may also indicate that stars d not remain in this stage for long. Stages K and appear to be much longer.

Prof. Shapley concludes that 95 per cent. of th stars in the Henry Draper Spectral Catalogue ar within 1000 parsecs of the sun; this region is onl one-millionth of that which he believes from hi researches on the clusters to be closely populate with stars. The paper also deals with the galacti concentration of different types. This is great fo B, A, slight for F, G, moderate for K, M.

Research Items.

BABYLONIA AND EARLY INDIA.—In further reference to the discovery of an early Indian civilisation at Mohenjo-Daro and Harappa (see NATURE, October 11, p. 584), it may be of interest to note that the chief points of resemblance between the objects from these sites and Babylonian antiquities to which Messrs. Gadd and Smith direct attention in the *Illustrated London News* of October 4, are as follows:—The seals are similar in shape to square stamp seals from Susa and Babylonia (3500–2500 B.C.), while the engraved bulls on them are distinctly Sumerian both in general appearance and in detail. They stand before a cult object in a position familiar in Babylonian art of all periods, and if the object were a sheaf, this would closely resemble the Sumerian picture sign *Zag*. Of the signs on the seals, obviously some form of writing, nine very closely, and seven partially, resemble Sumerian writing. The numeration system appears to be the same. A cylindrical piece of hæmatite with flattened ends from Mohenjo-Daro recalls a common type of weight from Babylonia. The curious stone rings may be compared to Babylonian mace heads, and, like them, may be votive offerings. Shell inlay, of which pieces have been found, is one of the most characteristic features of early Sumerian culture. The figurine of a cock from Mohenjo-Daro finds a parallel in a clay figurine of a hen from Ur. The style of brick building, with its drainage system and ornamentation of glazed bricks, closely resembles the style of buildings brought to light by the recent excavations at Ur. The miniature funerary pottery from Mohenjo-Daro is similar to miniature pottery from Ur which belongs to the second millennium. Painted pottery from both Susa and Babylonia antedates 3000 B.C. It belongs, however, to a period when metal was only just coming into use, as appears to be the case on the Indian sites.

ANCIENT CLEPSYDRÆ.—In most early civilisations means were devised for measuring time, and in ancient Egypt, while sun-dials or shadow-clocks of various types were used to indicate the passage of time during the day, water-clocks were employed at night. In an article in *Ancient Egypt* for June, Mr. R. W. Sloley describes two of these water-clocks. The older of them dates from about 1400 B.C. and was found at Karnak in 1904; it is now in the Museum at Cairo. In this type the surface of the water in a vase of the shape of the frustum of a cone fell through approximately equal intervals in equal periods of time as the water flowed out through a small orifice at the base. Among the Græco-Roman papyri found by Grenfell and Hunt at Oxyrhynchus is a fragment dating from the third century B.C. in which are given instructions for constructing the scales for one of these "outflow" water-clocks. The second one is probably an "inflow" clock, of which an example dating from Ptolemaic times was found at Edfu. In this type the water chamber is cylindrical, and it would appear that water flowed into it at a constant rate, causing a float to rise, though the lines which are scribed on the inside of the vessel scarcely support this view; on the other hand, they are difficult to see and could not have furnished a convenient means of reading the time directly. Casts of both of these water-clocks and one of a shadow-clock —which was used during the day in ancient Egypt—may be seen in the Science Museum at South Kensington. Thus in ancient Egypt the priests, by observing the culmination of different stars with the aid of a plumb-line and sight-vane, could determine sufficiently for their purposes different hours of the night; and with the water-clocks they could measure the passing of the hours. The shadow-clocks, which showed approximately the number of hours which had elapsed since sunrise, or which remained before sunset, were probably in more general use among the people; the distribution of water by a water-wheel or the working-periods of different pairs of oxen are still checked by little shadow-clocks made of a few pieces of millet (durra) stalk by the cultivator for his guidance.

CHILDBIRTH CUSTOMS AMONG THE INDIANS OF NEW MEXICO.—In *Man* for October, Dr. Elsie Clews Parsons describes a number of interesting customs relating to mothers and children among the Tewa Indians. An eclipse of the moon occurring during pregnancy is believed to cause deformities of mouth, foot, or hand. Therefore an expectant mother carries a key, stone, or something hard in her belt so that "the moon won't eat the baby." At an eclipse "when the moon dies," a woman is told not to go out of doors. The mother lies in for three days; on the fourth day the child is named, the attendant aunts, paternal and maternal, giving the names. In the course of the ceremony one of the aunts, called the navel mother, takes a mouthful of water from an abalone shell which has been used for bathing the child, and in which has been placed a fetish stone. With this water in her mouth she breathes along an ear of corn. The ear is waved in six directions, and the water ejected into the mouth of the infant. This rite is repeated for a second ear. The two ears are left on either side of the child for ten or twelve days. They are planted in the following year. The object of using these sacrosanct ears is that the baby may grow up perfect like the corn ear.

IMPLANTATIONS OF TESTIS AND OVARY.—Knud Sand in *Endocrinology* (vol. 7, pp. 273-301, 1923) gives a summary of his experimental results published in 1918 in a Danish monograph. He confirms Lipschutz's observations of hypertrophy of the clitoris following iso-transplantation and gives a preliminary account of two cases of testis-implantation in castrated homosexual human males and of the successful regeneration of a 12½-year old dog by means of resection of the left epididymis and right-sided vasectomy. He is of the opinion that Leydig's cells are substantially the most important tissue in the production of the male sex-hormones. In the matter of ovarian grafts, he finds that the place of implantation and the relatedness of donor and host are factors of slight importance. One point of considerable interest emerges from his observations on the artificial hermaphrodite. Apparently mammary activity with milk secretion can be produced in a male organism in the entire absence of corpora lutea, uterus, and pregnancy.

VASECTOMY AND SIMILAR OPERATIONS.—In *Acta Chirurgica Skand.* (vol. 64, pp. 387-426, 1922) Sand gives an English edition of his paper in Danish (Ugeskrift for Laeger., 1922) dealing with the operation of vasectomy for regeneration. He prefers to free the epididymis and resect a portion under local anæsthesia. An account is given of thirteen patients treated for senium præcox and of five younger men treated for impotency, who have been under observation for 3-21 months. In the first group nine, in the second four, benefited by the operation. The rest were unsuitable cases. Sand adopts a very cautious attitude. In *Skand. Archiv f. Physiologie* (vol. 44, pp. 59-75, 1923) the same author describes the case of

a 10-year old individual, brought up as a boy, with imperfect external genitalia. An explorative operation was performed and a uterus and two Fallopian tubes were found. On the right side there was an infantile testis, on the left what appeared to be an embryonic ovary. The author discusses the question as to what gonadial tissue should be implanted and suggests that when puberty is reached indications will be forthcoming. In *Abhandlungen aus Handwörterbuch der Sexualwissenschaft* (Marcuss and Weber, Bonn, 1923) Sand deals with certain aspects of sexual physiology (such as sex-reversal, hermaphroditism, gonad transplantation, regeneration, cryptorchism, vaso-ligation) in which he is an authority, in a concise yet encyclopædic manner.

MOLLUSCA OF COLORADO.—Mr. J. Henderson's previous catalogue of the Mollusca of Colorado, published in 1907, being out-of-date and out of print, the author has compiled a fresh one (Univ. Colorado Studies, vol. xiii. No 2), extending the area treated so as to include the States of Utah, Montana, Idaho, and Wyoming, which appear to constitute a rather distinct molluscan province, characterised (except at its northern border) by the absence of Polygyra and by the presence of Oreohelix. The amount of work which a valuable compilation of this sort entails is well gauged by the bibliography and synonymies, whilst its utility is enhanced by the numerous illustrations in the text and on photographic plates. By the time a further edition is required, and we trust it may be soon, it is to be hoped Mr. Henderson will have seen his way to a more modern system of classification, for it has long ago been shown that Vallonia and Cochlicopa belong to the Pupillidæ, being Orthurethra and not Sigmurethra, whilst Succinea represents the Heterurethra; further, Dr. Sterki, whom he has followed for Pisidium, will have realised that two years before he announced the discovery in America of the *Pisidium parvulum* of Clessin, it had been shown to have no existence, being a composite of other and well-known species, whilst the form to which Dr. Sterki attaches that name is probably the *P. moitessierianum* of Pallary.

THE MECHANISM OF ADAPTATION.—Professor L. Diels of Berlin, writing in *Naturen* for July on how the shapes of plants are affected by climate, puts the difficulty of explaining the mechanism of adaptation very clearly. While adopting a cautious attitude, he concludes that "in one way or another there may be some truth in the ideas of Lamarck, though experiment has not yet enabled us to decide wherein that truth consists. Without the Lamarckian theory geographic adaptations in the organic world would be nothing but a puzzle." Prof. Diels recognises, no doubt, that a whole-hearted acceptance of the Lamarckian theory still leaves us to find the mechanism by which new somatic characters are transmitted to the germ.

PARAMO PLANTS OF THE COLOMBIAN ANDES.—The Philadelphia Academy of Natural Sciences has turned its Annual Report into a Year Book, but the change seems to be confined to the title. Both in the first of the new series and the last of the old a large part is taken up by attractively written and well-illustrated accounts of explorations and collecting trips conducted on behalf of the Academy. As an example may be chosen Dr. F. W. Pennell's narrative of a botanical expedition through the Andes of Western Colombia in 1922. The features of chief interest were the lofty wind-swept moors known as Paramos, where the plants protect themselves from the bitter blasts either by donning a woolly coat, by spreading prostrate along the ground, or by forming dense cushions of almost rock-like hardness. The most characteristic of the woolly plants are the "frailejones," usually species of Epeletia, one of which reaches a height of 10 ft. Each isolated region of paramo appears to have developed its peculiar "frailejones," and Dr. Pennell suggests that a knowledge of the relations of these species would greatly assist a reconstruction of recent geological history in the northern Andes.

SKULL OF DINOTHERIUM.—In the Memoirs of the Geological Survey of India (vol. vii. No. 4, 1924) has appeared an account, by the late Captain R. W. Palmer, of an incomplete skull of Dinotherium. Remains of this genus are usually so fragmentary that every account of new material is of value even if it does no more, as in the present instance, than confirm previous accounts. There is no editorial note to show when the manuscript was completed, but it is likely that the author's health, before his much to be lamented death in October 1922, prevented his seeing a paper by Andrews published in 1921 and one by Forster Cooper in 1922 on the subject of Dinotherium, both in the Proceedings of the Zoological Society. The specimen described is an incomplete fragment of a skull showing the basal surface from the condyles to the pterygoid region. The anatomical features shown do not differ markedly from those described by the late Dr. Andrews for the celebrated skull of *Dinotherium giganteum* in the British Museum, but the new specimen being in better condition, certain points are more clearly established. With regard to the question of the validity of the Indian species *D. indicum* and *D. pentapotamiæ*, the author concludes that they cannot be upheld and that they are both to be referred to the European form *D. giganteum*. This agrees with the views already published by Forster Cooper which were the outcome of a study of material from Baluchistan.

THE STRUCTURE OF LIGHT.—In the October issue of the *Philosophical Magazine*, Sir J. J. Thomson gives an account of a mental picture based on the idea of tubes of force which he has used for some time to reconcile the optical properties of light, which point to a wave theory, with the electrical properties, which demand some form of corpuscular theory. When an atomic electron falls towards its positive nucleus, the tube of force connecting them is not shortened, but forms a loop which may detach itself from the rest of the tube and move off as a free ring. Its emission is radiation, and the energy radiated is concentrated in the ring. Such a free ring may strike another tube and, in coalescing with the tube, lengthen it either temporarily or permanently. If the association is temporary only and the ring is thrown off, there is no absorption; if permanent, the electron has moved out from the nucleus and absorption has taken place. This picture is shown to be in keeping with the quantum theory and the principal facts of absorption and resonance.

THE HARDNESS OF SCATTERED X-RAYS.—An apparatus for measuring the hardness of X-rays, scattered through different angles, is described by Messrs. F. Dessauer and R. Herz in the *Zeitschrift für Physik* of August 28. Preliminary measurements have been made, in which the X-rays were filtered through 4 mm. of aluminium, so that they belonged to a narrow spectral region; they were sent in a narrow beam through holes, 5 mm. in diameter, in a series of concentric cylindrical lead screens, on to a sphere of paraffin placed at the axis of the cylinders. A series of holes in the lead cylinders allowed scattered beams, about 8 mm. in diameter, to pass outward at

...nles 30°, 60° . . . 150°, and fall upon a photo-...phic film, which was bent into a cylinder coaxial ...h the lead screens; the lower half of each beam ...ed through an aluminium filter. A movable ...d screen, with rectangular openings, made it ...sible to expose narrow vertical strips of the small ...ular patches formed on the photographic plate, ...o regularly increasing periods, 100, 200, 300 . . . ...utes, up to a total exposure of ten hours; thus ...h calibration of the photographic blackening, as a ...asure of the intensity of the radiation, can be ...le separately for each angle of scattering, *i.e.* for ...h wave-length. Since the whole series of observa-...ns is made simultaneously on the same photo-...phic plate, some of the possible errors are elimin-...d and others greatly reduced. It is possible to ...uce, from the photometric measurements of the ...ckening, the wave-lengths of the rays scattered at ...erent angles. The results obtained agree fairly ...l with those calculated by means of Debye's ...ory, thus confirming Compton's results. Measure-...nts in which monochromatic radiations are ...ployed are in progress.

The Geiger α- and β-Particle Counter.—Dr. H. Geiger discusses the working of the pointed electrode counter in the *Zeitschrift für Physik* of August 28. If the counter is 2 cm. in diameter, a β-particle produces primarily some 50 ions, or 2×10^{-8} electrostatic units; while, according to the voltage employed, the rush of electricity will be from 0·1 to ...limit. It seems clear then that an α- or β-particle ...uses a momentary discharge; but it is difficult to ...explain why this discharge breaks off so suddenly. H. Geiger has connected the point electrode to a ...sing electrometer, earthing them through a high ...sistance such that the time the charging rush lasts ...small compared with that which it takes to leak ...ay; if a capacity several times as large as that of ...e electrometer is then connected in parallel, the ...eflexions are reduced, and are roughly inversely ...proportional to the capacity, so that in each discharge ...e same quantity of electricity flows. It is not the ...e of voltage caused by the current rush which ...ops the discharge, for if this were the case the ...eflexion would be independent of the capacity. ...he point electrode in general requires a certain ...preparation before it will work properly; the form ...f the point and the degree of polish have little ...influence, but heating to incandescence will generally ...make the point active. Apparently the point be-...omes covered with a surface layer having a high ...electrical resistance; since platinum is a suitable ...material, this layer can scarcely consist of an oxide; ...he alteration seems rather to depend on the gas ...which covers the metal. Janitzky has shown that in ...n X-ray tube no discharge takes place from an ...electrode which has been perfectly freed from gas. ...n Geiger's theory, when a rush takes place, the ...outside layer of this surface film becomes charged, ...and the potential difference between this surface and ...he surrounding walls falls rapidly, so that the ...current stops soon after it commences.

A New Bleaching Reagent.—A new bleaching ...reagent for use in laundries is described by Dr. R. ...Seibelmann in the *Chemiker Zeitung* (1924, vol. 48, ...685) under the name of *activin*. This compound is ...the sodium derivative of *p*-toluene sulphochloramide, ...$CH_3 . C_6H_4 . SO_2 . NClNa + 3H_2O$, and belongs to the ...class of chloramines. Although the oxidising power ...of activin is due to "available" chlorine, it is much ...milder in its action than the hypochlorites though ...more effective than sodium perborate. Moreover, it ...possesses several advantages over the latter. Thus it is not easily decomposed by heat and it is not sensitive to the catalytic action of traces of copper and other metals, a property which is apt to render sodium perborate destructive to fabrics. It acts as a powerful germicide, being indeed comparable with corrosive sublimate in this respect.

Effect of Motion on Chemical Change.—The April-July volume of the *Compte rendu des Séances de la Société de Physique*, of Geneva, contains a paper by Duparc and Molly on the above subject. The authors examined the reaction between marble and a solution of ammonium chloride, both when the mixture was agitated, so that the pieces of solid rubbed against one another, and again when the liquid was merely circulated around the pieces of solid. It is claimed that the results were different in the two cases. In the first experiment the quantity of calcium carbonate dissolved increased to a maximum and then decreased, whilst in the second experiment a state of equilibrium was reached. It was shown that in the first case the solution contained free ammonia, and the reaction was assumed to occur according to the equation: $2CaCO_3 + 2NH_4Cl = CaCl_2 + Ca(HCO_3)_2 + 2NH_3$, whilst in the second case the reaction $CaCO_3 + 2NH_4Cl = CaCl_2 + (NH_4)_2CO_3$ attained a state of equilibrium.

The Delaware River Bridge.—This suspension bridge is in course of erection over the Delaware River between Philadelphia and Camden. The estimated amount of load which the cables will ever have to carry is nearly 60,000 tons, and requires two 30-in. diameter steel cables, each weighing nearly a ton per foot of length and each subjected to a maximum pull of 20,000 tons; there will be 18,000 wires in each cable. The design and construction of the anchorage for resisting these enormous forces is of particular interest, and an extremely lucid account will be found in the Journal of the Franklin Institute for September, where the design is treated by Mr. Allston Dana, of the Delaware River Bridge Joint Commission, and the construction by Mr. Montgomery B. Case, who is the senior resident engineer on the bridge. The anchorages are separated by a distance of about 0·6 mile, and will be concrete structures faced with granite, 218 ft. long, 190 ft. wide, 175 ft. above ground, and with foundations extending down to rock 65 ft. below ground in Philadelphia and 105 ft. below ground in Camden. Each anchorage will weigh 5 or 6 times as much as the pull exerted on it by the cables. The cables will enter the anchorage at points 130 ft. above ground and at an inclination of 8° with the horizontal; they will then bend over the top of an inclined steel tower and will pass down into the anchorage at an inclination of about 45°. Forty feet down each cable will be incased in a cast steel band the lower part of which is bell shaped, and the cable will then flare out in all directions, and will be looped round a group of 61 cast steel shoes connected to eyebars, which in turn will be connected to anchor girders placed as far down in the corner of the anchorage as practicable. The design of the anchorage structures introduces some very interesting calculations which are explained clearly by Mr. Dana. The caissons were sunk by dredging and their behaviour varied widely with the class of material under penetration. In sand and gravel the caissons followed the dredging gradually, whilst in clay or disintegrated rock they frequently held up until the excavation was 10 ft. or more below the cutting edge, when a sudden drop would occur and the cutting edge forced the material to the centre of the dredging. The paper is profusely illustrated with drawings and photographs, and we can recommend its perusal to all students of civil engineering.

Transmission of Stimuli in Plants.[1]

MR. R. SNOW has conferred a real benefit on botanists by reviewing Ricca's important experimental investigation on the conduction of stimuli in Mimosa, and by discussing the evidence for the conclusions of that Italian investigator which originated such an unexpectedly simple theory for the conduction of stimuli in plants. In the paper before us Mr. Snow describes how the experiments which Ricca performed on the conduction in the stem of *Mimosa spegazzinii* were repeated on *M. pudica*, and states that Ricca's explanation of the conduction, as depending on the transference of a hormone in the transpiration-current in the wood of the stem, has been tested and may be accepted as correct.

It will come, however, as a surprise to most physiologists that Mr. Snow does not consider this mechanism adequate to explain all the forms of conduction in *Mimosa pudica*. He believes that there are three types of transmission, namely, (1) The "normal" conduction in the transpiration-stream, elucidated by Ricca; (2) "high speed" conduction in the cambium or inner layers of the phloem, and (3) leaf-conduction in the phloem. Such a point of view demanding a special hypothesis to meet each type of conduction is not likely to find favour unless there is evidence to show conclusively that the original theory alone is unable to explain the experimental results. It may be stated at once that such evidence does not appear to be forthcoming.

First, with regard to the "high speed" conduction: This type is observed when a small lesion is inflicted on the inner layers of the phloem of the stem, or, occasionally, when an internode of the stem is cut through. In these cases the nearest one or two leaves above the cut are seen to fall practically simultaneously with the administration of the stimulus, while in "normal" conduction several seconds are required to traverse an internode. The reaction in the cases of "high speed" conduction also differs from that of "normal" conduction in that it involves only the main pulvinus and not the pinnules of the leaf. From the evidence, however, which Mr. Snow presents it does not seem probable that these two types differ essentially from one another. Assuming the liquid in the xylem is in tension, the rapidity of the motion of a hormone introduced into the xylem will depend on the relation of the cross-section of the conduit, in which the hormone moves, to the volume of the liquid moved by transpiration and by the elastic recovery of the tissues. Thus, if the motion upwards is confined to a slender linear series of tracheæ, the velocity will be high, while if a woody conduit having a large cross-section can be utilised, then the velocity will be small.

The method of experimentation described by Mr. Snow on p. 352 of his paper is just such as would produce a rupture of the tensile sap in one or two tracheæ and so allow the tensile liquid, having dragged in the hormone from the wounded cells, to hurry it upward in an instantaneously shortening filament of sap. The volume of this rising fluid is necessarily very small. Hence it is found able to affect only the pulvini of the reacting leaves and does not extend to the pinnules. Similarly it is evident that, where an internode is cut across, the velocity of the transfer of the hormone will depend upon the relation just pointed out. Consequently, the accident as to how exactly the cut is made, together with its chance relation to the transverse septa in the vessels, etc., will decide whether the conduction will be "high speed" or "normal." In this connexion Bode's observation should be borne in mind. He found that the tensile sap in tracheæ is ruptured by the pressure of a metallic point on the cells adjacent to the tracheæ. Thus we must infer that a rupture will take place in the sap just as the pressure of the blade producing the stimulus injures the semi-permeable protoplasm of the cells.

In the second place, Mr. Snow's reasons for assuming that the mechanism for the transmission of stimuli in leaves is fundamentally different from that in stems do not appear convincing. His first argument for this conclusion is that the rapid conduction observed in submerged leaves, or in those in a nearly saturated space, would be impossible if conduction depended solely on the movement of the transpiration-stream. It must be remembered, however, that, even in leaves in these conditions, there is evidence that tension exists, and that the turgescence (suction force) of the uninjured cells will draw liquid from the permeable injured cells back along the xylem. The very small cross-section of the xylem in the leaves will render the velocity of this motion comparatively great. Mr. Snow also believes that the fact, that in the leaf basipetal is as fast as acropetal conduction, shows that the conduction-mechanism of the leaf differs from that of the stem. This is just what we would expect if the hormone travels in the tensile sap; for the tension is hydrostatic and the resistance is the same in both directions.

Mr. Snow further finds support for his contention in Herbert's observation, that the velocity of conduction in the leaf is dependent on the intensity of the stimulus, while in the stem it is not so. Mr. Snow's own observations on "normal" and "high speed" conduction show that this rule is not without its exceptions. The fact that the volume of the tracheæ of the leaf is small compared with that of the stimulated cells furnishes a rational explanation of those cases where this difference is observed. This also accounts for the greater rapidity and greater certainty of the conduction in the leaf.

Again, the observation that an eosin solution is not always drawn back into the tracheæ of a responsive leaf cut under the stain, does not show, as Mr. Snow suggests, that in these cases there is no basipetal current in the tracheæ available for transport. Rather the failure of the stain to enter and pass down the xylem is almost certainly due to the unwettable surface of the leaf, which secures that the air adhering to the surface enters the tracheæ and prevents the eosin following the retreating sap. Mr. Snow himself instances a case where the eosin was drawn in 1·25 cm. in 60 seconds. In my own experiments I have observed a downward motion of the dye of 2·75 cm. in 40 seconds in the same circumstances. Lastly, in Mr. Snow's experiments, where transmission was observed in leaves after the continuity of the xylem had been broken by a cut not involving the phloem, there is no evidence produced that the hormone did not pass in the liquid filling the cut. Such transference has been shown to take place in stems and it is hard to see why it should not do so in leaves.

With regard to the nature of the hormone responsible for evoking the reactions, Mr. Snow has made some interesting observations. The hormone may be rendered inactive by dilution, and probably by boiling. Ricca found that of *M. spegazzinii* was not thermolabile. It is not precipitated by a protein-precipitant. It diffuses through a collodion shell. It is not injured by desiccation, nor by treatment by strong alcohol.

HENRY H. DIXON.

The Scattering of X-rays.

N exceptionally successful session of Section A the British Association at Toronto this year, s no discussion created such widespread interest which centred round the papers of Prof. A. H. on of Chicago, and Prof. Duane of Harvard, on attering of X-rays. The subject is one which d considerable influence on the development of n physical theory. It was as a result of the of scattering advanced by Sir J. J. Thomson arkla was able to deduce from his experiments he number of electrons in the atom was approxi- equal to one-half of its atomic weight, a result ined by other methods some years afterwards oseley. Later developments indicated that the menon of scattering was more complex than son's theory assumed. The work of various ers on γ-rays showed that the absorption of rays was greater after scattering than before, which suggested that during the scattering was a shift in the wave-length towards the long length end of the spectrum. Similar results had obtained with X-rays. Recent developments of technique have made it possible to carry out ments of a much higher order of accuracy and placed at the disposal of the physicist powerful s of monochromatic radiation. It was natural, ore, to expect that the problem would be ked anew, and this has been done by several vers, notably Compton and Duane.

mpton's work was undertaken primarily to test ruth of a theory advanced independently by lf and by Prof. Debye of Zurich. The theory is eat interest, and a brief sketch may be given. eas the original theory proposed by Thomson based on classical electromagnetic conceptions, of Compton and Debye is founded on the um theory. In the simplest case a quantum of tion of frequency ν falls on the scattering sub- e, and may be considered as colliding with an on which is either free or very loosely bound to om. This electron takes up some of the energy e quantum, and the radiation passes on as a tum of somewhat lower frequency. The re- der of the energy appears as kinetic energy of electron. It is assumed that, during the en- ter between the radiation and the electron, the of conservation of energy and momentum are ed. The energy of the quantum is $h\nu$ and its entum is taken as $h\nu/c$, where c is the velocity of h. If the equations representing the conservation ergy and momentum are solved, it is found that change in wave-length of the radiation scattered direction making an angle θ with the original n is given by $h/mc(1-\cos\theta)$ or $0{\cdot}024(1-\cos\theta)$ Å.

this theory is correct, and we allow a beam of chromatic X-rays to fall on a scattering sub- ce and analyse the radiation scattered at an e θ, we should expect an increase in wave-length $0{\cdot}024(1-\cos\theta)$. Such a change is well within the e of measurement of modern X-ray spectroscopy. pton conducted a series of experiments on these s, and found that in the scattered radiation two e-lengths predominated, one being identical with, other longer than, that of the unscattered beam. difference in wave-length was found to agree itin experimental error with that predicted by the ery. Again, the separation of the two depended he angle of scattering in just such a manner as cipated by the theory. Further, a series of rption experiments yielded results consistent his hypothesis, and, finally, a study of C. T. R. Wilson's track photographs revealed the existence of electrons with the energy and direction of motion to be expected.

Further confirmation of the Debye-Compton theory came from independent observers, notably Profs. Ross and Bergen Davis. Ross used a photographic method instead of the ionisation apparatus employed by Compton. He found two lines on his plates, one corresponding to the wave-length of the original beam, the other to a radiation of longer wave-length. The separation increased with the angle of scattering as in Compton's experiments.

Had it not been for the experimental work of Duane, there is little doubt that these results would have been generally accepted as affording strong evidence in favour of the theory, if not as entirely establishing it. For the past year or two, however, Duane and his research school have been engaged on a series of experiments on the radiation emitted from various substances when bombarded by X-rays. They find, in addition to radiations identical with the primary beam, other radiations of longer wave-length. Their measurements indicate that these can be explained as due to the photoelectrons ejected from the matter by the primary radiation. It requires a certain amount of energy to eject an electron from its parent atom, the amount depending on the energy level from which it has to be removed. The kinetic energy of the electron will be less by this amount than the energy corresponding to a quantum of the X-radiation. If, in their turn, these electrons strike other atoms of the scattering substance, they will give rise to X-rays the maximum frequency of which will correspond to their kinetic energy in accordance with the Einstein equation $\frac{1}{2}mv^2 = h\nu$.

Duane finds that his experiments are consistent with such an explanation. It is clear that, on this theory, different substances will give rise to different radiations according to the energy required to remove an electron from the matter. On the Compton-Debye theory the wave-length of the softer radiation is independent of the nature of the scattering substance. In the case of carbon bombarded by the K radiation of molybdenum—the rays used by Compton —the chief effect observed by Duane nearly coincides with the Compton effect, but for heavier atoms the two theories give rise to radiations of different wave-lengths. Duane found that, with his apparatus, he was unable to find evidence for the existence of the effects observed by Compton, Compton, on the other hand, could not repeat satisfactorily Duane's experiments. A matter of such importance could not be left in such a position. Each observer investigated the apparatus used by the other and convinced himself of its trustworthiness. Duane observed that the only obvious difference in the experimental arrangements was that Compton's X-ray tube was enclosed in a wooden box covered with lead, while his own tube was not so enclosed, the tube being in one room and the rest of the apparatus in the adjoining room. Improbable as it appeared that such a difference could account for the difference in the experimental results, Duane tried the effect of such a box and found to his surprise that, in addition to the effects he had previously observed, a new peak appeared in approximately the position observed by Compton. The exact position of this effect depended on the orientation of the box. At the time of the Toronto meeting this represented the state of affairs.

In the general discussion various other members took part. Prof. Webster gave a detailed description of the experimental arrangements used by Ross, and

contended that the box in which Ross's tube was enclosed could not possibly account for the results he obtained. Prof. Gray described experiments on γ-rays and showed that they were consistent with the Compton theory. Prof. Raman made an eloquent appeal against a too hasty abandonment of the classical theory of scattering. Compton sketched an extension of his theory in which he considered not only free electrons but also those which were more tightly bound. He showed that the extended theory gave rise in the limiting case to the formula used by Duane and therefore embraced Duane's results. The fundamental difference between the two theories remains; Duane uses only the well-established quantum energy equation, while Compton in addition introduces the idea of conservation of momentum in the interaction between the radiation and matter. There are difficulties in the way of both theories, but at the present stage of the experimental work it is needless to dwell upon them. Before the theoretical side of the question can be satisfactorily discussed, further experimental work must be done. At the time of the meeting each observer appeared to have almost overwhelming evidence in favour of his point of view, and had the audience only had to listen to one side—either side would have done equally well—it would probably have been convinced as to the accuracy and soundness of the views advanced. As it was, however, the average member left the meeting inclined to echo the sentiments of the lover in the "Beggar's Opera" who sings

"How happy could I be with either,
Were t'other dear charmer away!"

The Spectrohelioscope.[1]

By Prof. GEORGE E. HALE, For. Mem. R.S.

MONOCHROMATIC images of the sun, photographically recorded with the spectroheliograph, reveal the phenomena of the solar atmosphere in projection against the disk. The light from a spectral line of calcium, hydrogen, or other substance is singled out by a narrow second slit, which moves across the plate while the first slit moves across the solar image. A monochromatic picture is thus built up of countless narrow slit images, recorded side by side in slow succession.

The vortices and other significant structures thus disclosed, with the exception of an occasional brilliant eruption or unusually dark hydrogen flocculus, are beyond the reach of visual observation with the spectroscope. The simple method of opening the slit, which affords an excellent view of prominences at the sun's limb, because the light of the sky is sufficiently weakened by dispersion, is seriously limited when applied to the intensely brilliant disk. Even with the highest dispersion the slit cannot be opened sufficiently to reveal the characteristic structure of the dark hydrogen flocculi. Moreover, with a widened slit the image is not strictly monochromatic.

This simple expedient of rapidly oscillating the narrow spectroscope slit, and synchronously with it a second slit transmitting the Hα line to the eye, was tried by the earliest observers of the prominences. With suitable precautions this device gives excellent images of prominences through persistence of vision, but it did not survive the introduction by Zoellner and Huggins of the wide slit method, and apparently was not tried for observing the sun's disk.

Many years ago I made some preliminary trials of the oscillating slit method with the 30-foot spectroscope and 60-foot tower telescope on Mount Wilson. I have only recently found opportunity to develop a satisfactory instrument based on this principle with which I have now secured good visual observations of both bright and dark flocculi.

An image of the sun two inches in diameter, given by a cœlostat and a 12-inch objective formerly belonging to the Kenwood Observatory,[2] was observed with a grating spectroscope mounted horizontally. In this instrument the light passing through the slit falls on a 6-inch concave mirror of 13-feet focal length, which returns a parallel beam to a point just below the slit, where a 6-inch plane grating is mounted. This sends the diffracted beam to a second 6-inch concave mirror, supported below the collimating mirror, which forms an image of the spectrum in the same plane as the first slit, and immediately below it. A fixed second slit at this point permits any part of the spectrum to be isolated. The grating was ruled by Jacomini with about 15,000 lines to the inch on the ruling machine of the Mount Wilson Observatory, with a diamond ground after Anderson's formula so as to give great brightness at the red end of the first order spectrum. The definition is perfect, and the brightness near Hα remarkable, as the attempt to concentrate most of the light in one spectrum and to favour the red end proved successful.

Suppose the first and second slits to be carried at opposite ends of a brass bar, mounted on a bearing half-way between them and thus free to revolve about this centre. Place the bar vertical, and turn the grating until the Hα line in the bright first order is bisected by the second slit. With the optical arrangement employed, a small displacement of the first slit to the right causes an exactly equal displacement of the Hα line to the left. Thus if the bar is oscillated back and forth by means of a small electric motor, a monochromatic image of the sun will be seen through a low power positive eyepiece focussed on the second slit.

This arrangement serves very well for the observation of prominences at the limb, where they can be seen at their full height with slits of moderate width. It also shows exceptionally bright or dark flocculi on the disk, though the slits must be narrower in order to give sufficient purity and reduce the brightness of the continuous spectrum. For flocculi of ordinary intensity the best results have been obtained with the aid of multiple slits, five at each end of the bar, 0·003 inch wide and 0·08 inch apart. A fixed slit, slightly less than 0·08 inch wide, must be used behind the upper slits, to prevent the formation of overlapping spectra. Two complete oscillations of the bar per second, corresponding to twenty illuminations of the retina, give a sufficiently steady image. A rotating disk, carrying a large number of radial slits, is in some respects a more satisfactory device for the same purpose.

This instrument, which may appropriately be called a spectrohelioscope, should prove a valuable auxiliary of the spectroheliograph in several kinds of work. It will permit the rapidly changing forms of eruptions on the disk to be followed visually, and be of special service in deciphering the curious differences of structure sometimes found on photographs of flocculi taken simultaneously with the opposite edges of Hα. As the oscillating bar can be moved toward red or violet by a micrometer screw while observations are being made, the possibility of passing instantly from one edge of the line to the other should assist in the interpretation of the spectroheliograph results.

Oil-Cracking.

A PAPER on "Recent Development in the Art of Cracking," by A. E. Dunstan and R. Pilkethley, was read before the Institution of Petroleum Technologists on October 7. The object of "cracking" is to change in a lighter constituent from hydrocarbon oils by temperature treatment, under suitable conditions. During the last few years there has been little advance in our knowledge of cracking from the chemical point of view, and most of the problems connected with it have been more of an engineering quality. Very little work has been done on the examination of the residues left after the cracked gasoline has been removed from the synthetic crude oil.

Vapour phase processes working at atmospheric pressure have not been very successful; most of the processes developed worked under 300 to 400 lb. per sq. in. pressure, and no particular advantage in the use of extremely high pressures is apparent. The Bergius process was at first directed towards the production of artificial coal from wood, cellulose, etc., and a black powder containing 84 per cent. of carbon was obtained at 349° under 160 atm. pressure. This was susceptible of hydrogenation by heating to 400° in the presence of hydrogen for some hours, and over 90 per cent. of the product was soluble in benzene. Later experiments, natural coal mixed with oil was converted up to a 90 per cent. yield of oil, yielding fractions suitable for use as fuel oil.

The experiments of the present authors throw some doubt on the hydrogenation of the liquid products. Processes for cracking in the vapour phase, *e.g.* the Winnage plant, in which the vapour of the hydrocarbon is passed over heated iron oxide, were described. The Dubbs process is two-stage, the oil being cracked in tubes in the liquid state, then passed to a reaction chamber where carbon is deposited, and the vapours then passed to a dephlegmator which separates heavy oil from lighter cracked vapours. The pressure is about 150 lb. per sq. in., and the process is commercially successful. The Cross process differs from the Dubbs process in the form of the apparatus, and the pressure and temperature conditions.

The Auld, Dunstan and Hering process is described. It is substantially a liquid phase operation throughout, the pressure being sufficiently high to maintain all but the lightest products liquid (25-30 atm.); the yield of light spirit is restricted for definite reasons, the temperature range is definitely fixed for each oil, and the rate of flow is controlled according to the temperature. The oil is first carefully heated to know the optimum temperature, quickly raised above this temperature, and then allowed a certain time of contact in a reaction vessel, where carbon is deposited. The cracked oil is drawn off from the highest point of the vessel, condensed or dephlegmated, and discharged into a gas separator. Experimental plant recently used is also described, and the important problem of refining, including distillation over bauxite or activated carbon, is discussed.

University and Educational Intelligence.

CAMBRIDGE.—Mrs. Marshall, widow of the late Prof. Alfred Marshall, has offered to the university a most valuable selection of books from her husband's library for the use of students in economics, together with 1000*l.* to be used in expenses connected with the books and with any arrangements which may be made for facilitating economic research.

Dr. Dollo has been appointed to represent the University at the fiftieth anniversary of the founding of the École Polytechnique of the University of Brussels. Prof. A. C. Seward has been appointed as a Trustee of the Percy Sladen Memorial Fund. Mr. T. A. Carroll, Sidney Sussex College, has been appointed assistant director of the Solar Physics Observatory in succession to Mr. E. A. Milne, who has resigned on being appointed to the Beyer chair of applied mathematics at the University of Manchester.

At Emmanuel College the following have been elected to Research Studentships: G. A. Reay, University of Aberdeen (biochemistry); W. W. Grave (Romance literature); and P. A. Taylor (mathematics).

CORK.—Applications are invited for the professorship of chemistry at University College. Particulars are to be had from the secretary.

LONDON.—Birkbeck College, which celebrated its centenary last year, announces in its calendar for 1924–25 that great development in accommodation and in facilities for study in the college is probable in the near future. Appended to the calendar is an imposing list of original publications by members of the staff and students, chiefly in chemistry, physics, zoology, geology, classics, and modern languages.

Prof. S. L. Loney has been elected chairman of Convocation, and Sir Josiah Stamp representative on the Senate of the Registered Graduates in Science.

DR. A. T. DE MOUILPIED, of the British Dyestuffs Corporation, has been appointed professor of science at the Royal Military Academy, Woolwich, in succession to Prof. J. Young, as from January 29 next.

APPLICATIONS are invited for the headship of the chemical department of the Midland Agricultural and Dairy College, Sutton Bonington, Loughborough. Particulars of the appointment may be had from the principal.

A LECTURER in agricultural chemistry is required at the Cheshire School of Agriculture, Reaseheath, Nantwich. Applications, upon a prescribed form, must be sent to reach the principal of the school by November 7 at latest.

DR. ALEX HILL, secretary of the Universities Bureau of the British Empire, 50 Russell Square, London, W.C.1, informs us that the six great lines engaged in the passenger service to Australia and New Zealand have agreed to grant eight free first-class return tickets, yearly, to University graduates desirous of studying problems connected with the development of the resources of the Dominions, or of holding temporary teaching posts. The selection of the recipients is to rest with a committee of the Universities Bureau.

THE Senate of the University of Sydney has resolved on the appointment of a chief executive paid officer, with the title of Vice-Chancellor, to take the place of the Warden and Registrar, Mr. H. E. Barff, who has just retired. The necessary legislation is being drafted, and in the meanwhile Prof. MacCallum has been asked to undertake the duties of Warden temporarily. Prof. J. I. Hunter and Dr. N. D. Royle have been invited to deliver the Doctor John B. Murphy oration in surgery at the meeting of the American College of Surgeons to be held in New York on October 20.

THE following candidates have been nominated for election as Parliamentary representatives of the universities of Great Britain and Northern Ireland:—CAMBRIDGE (2)—Mr. James Butler (Ind.), Sir Geoffrey Butler (U.), and Mr. J. F. P. Rawlinson (U.). LONDON (1)—Sir John Rose Bradford (U.), Dr. F. G. Bushnell (Lab.), Dr. E. G. Graham Little (Ind.), and Prof. A. F. Pollard (Lib.). OXFORD (2)—Lord Hugh Cecil

(U.), Prof. Gilbert Murray (Ind.), Sir Charles Oman (U.). SCOTLAND (3)—Sir George Berry (U.), Mr. D. M. Cowan (L.), Sir Henry Craik (U.), Rev. J. M. Munro (Lab.). WALES (1)—Mr. G. M. L. Davies (Lab.), Capt. E. Evans (L.). QUEEN'S, BELFAST (1) —Col. T. Sinclair (U.).

THE Municipal College of Technology, Manchester, announces reductions in fees for degree and certificate courses amounting to 10 per cent. in favour of residents in Lancashire and Cheshire (who were already favoured to the extent of 16 per cent.), and 16 per cent. in favour of students from other parts of the British Empire. According to the Calendar for 1924–25, courses of post-graduation and specialised study and research are offered in mechanical engineering (including hydraulic experimental work, motor-car engineering, and eight other subjects), electrical engineering, municipal and sanitary engineering, applied chemistry (including textile fibres, paper manufacture, metallurgy, india-rubber, brewing, coal-tar and dyestuffs, and photography), textile industries, applied physics, and mining engineering. Last year, ten research scholarships of 100*l*. each were awarded by the College. Among other technical college calendars recently received are those of Loughborough College (departments of mechanical, civil, electrical, automobile, and commercial engineering, pure and applied sciences including chemical technology, extra-mural adult education, and school of industrial and fine art) and the Battersea Polytechnic (engineering, pure and applied mathematics, physics, chemistry and technological chemistry, photography, hygiene and public health, domestic science, and arts and crafts). The subjects of the Polytechnic's technological courses include oil industries, paper industries, and flour-milling.

THE Vice-Chancellor of Oxford has contributed to the October number of the *Empire Review* an article on "Oxford and the Empire." Starting with the great Elizabethans, Sir Humphrey Gilbert of Christ Church, his half-brother Sir Walter Raleigh of Oriel College, and Richard Hakluyt of Christ Church, he gives a list of Oxford men who have during the last four hundred years played distinguished parts in building up the British Empire or the ideas on which it is based, or in its governance. He points out that of the twenty-five governors-general of India from Warren Hastings to Lord Curzon, fourteen were university men; and of these, twelve were educated at Oxford, nine of them at Christ Church. He discusses the features of university life which favour the development of those qualities which go to make good administrators, and deplores the fact that the Indian Civil Service no longer attracts Oxford graduates. Of the Rhodes scholars, he singles out for mention the late Sydney Fairbanks of Rhodesia, who chose an Oxford career especially with the view of developing his own plans of child emigration. The influence on Oxford of Rhodes scholars from the overseas Dominions and the influence of their Oxford training on their subsequent careers is a theme deserving more attention than it has hitherto received. It is to be hoped that the Vice-Chancellor's article may lead to studies of this theme and also of the relations between other universities and the Empire. As Prof. Newton says in his new book, "The Universities and Educational Systems of the Empire," every university is, in a sense, imperial, but the peculiarly imperial university is one that by long prescription, by eminent advantages of situation, and by the labours of a line of great investigators, has acquired prestige and reputation as a *studium generale*.

Early Science at the Royal Society.

October 27, 1670. There was read a Latin letter from Signor Montanari of Bologna, expressing the singular esteem which he had of their institution. —Mr. Oldenburg produced another Latin letter from Erasmus Bartholinus, M.D. of Copenhagen, giving notice of a certain transparent stone, a kind of selenites, sent out of Iceland, and having different positions, a double, quadruple, and sextupline refraction; as also an electric virtue.

October 28, 1663. At a meeting of the Society the president reported to them, that because the stationers and printers are of one and the same company, and may, by the concession of both sides, practise both trades promiscuously, the Society might choose a stationer for their printer without violation to their charter, which gives them power to choose printers. Whereupon Mr. John Martyn and Mr. James Allestry being recommended, it was put to the question, whether it should be the question, that the office of printer to the Royal Society should be conferred jointly; and it was carried in the affirmative; after which those two persons were put to the ballot, and chosen.

1669. Mr. Oldenburg mentioned that Dr. Wren desired to borrow that engine of his, in order to make a scheme and description thereof for the satisfaction of Mons. Huygens, who, though he had much applauded that invention, and the demonstration of it, yet had made some objection against its practicableness.

October 29, 1662. Dr. Wilkins and Dr. Goddard gave an account of the experiment which had been made of a lamp burning under water in a vessel of four gallons, the ellychnium being one single thread of cotton, and the lamp wholly under water: the flame lasted eleven minutes.—They were desired to repeat the experiment several times; as also to try it with some live creatures.

October 30, 1672. An account being demanded of what trials had been made for the improvement of the reflecting telescope of Mr. Newton, Mr. Hooke said, that hitherto he had wanted a mould of a sufficient bigness for a speculum, designed by him of fifteen inches diameter, for a tube of ten feet long; but that he hoped to have, soon, such a mould cast, wherein a speculum of that bigness might be well wrought and polished.

1674. The form of the summons to the Society for returning to their weekly meetings being read again, it was thought fit to omit the names of the persons who were to entertain the Society, and to let it be as follows:—these are to give notice that the Royal Society intends to return to their public meetings on Thursday, being the 12th of this instant November 1674, in Gresham College; at three of the clock; at which time and the following days of their meetings the company will be entertained with experimental exercises, to be performed by several eminent members of the same, in order to a more vigorous prosecution of the ends of their institution.

October 31, 1667. Mr. Evelyn presented the Society with his wooden tables, having the veins and arteries of the human body fixed on them.—A report being made of Dr. Allen's scrupling to try the experiment of transfusion upon any of the mad people in Bethlem-hospital, it was ordered that he should be desired by Mr. Hooke to give a meeting at Sir George Ent's house on the Monday following to some of the physicians of the Society, as Sir Theodore de Vaux, Dr. Clarke, Dr. Lower, Dr. Balle, and Dr. King to consider together, how this experiment might be most conveniently and safely tried.

Societies and Academies.

LONDON.

Optical Society, October 9.—E. T. **Hanson**: Some problems in the theory of optical diffraction. A semi-infinite plane may be looked upon as a wedge the internal angle of which is zero. The application of Kirchoff's formula in the latter case is considerably extended, it being shown that, through a region of not too small dimensions comprising the whole of the boundary of the geometrical shadow, the solution obtained is identical with the accurate solution. An expression is found for a plane wave incident at any angle upon a semi-infinite screen. An approximate expression is also found for the disturbance distributed over a straight slit due to a wave incident obliquely. Kirchoff's formula has been applied, apparently for the first time, to an area of disturbance which is non-uniform.—W. M. **Hampton**: The annealing and re-annealing of glass. Relations connecting the strains present when cooling commences, strain applied to gradient, and strain present after cooling, are obtained and the equations are applied to the case of slabs. The considerations affecting the temperature and conditions of annealing are discussed and rules giving annealing temperature, annealing time and rate of cooling for various kinds of glass are included.

PARIS.

Academy of Sciences, September 22.—M. A. Laisonval in the chair.—Paul **Appell**: The order of a non-holonomial system.—E. **Mathias**: The theory of the lightning flash.—Georges J. **Rémoundos**: Couples of functions of one variable corresponding to the points of an algebraic curve of genus higher than unity and on a generalisation of a theorem of M. Picard.—Benjamin **Jekhowsky**: The elements of the planet Algiers M = 1924 PQ.—E. M. **Antoniadi**: The retarded decrease of the southern snows of Mars and its coincidence with the solar minimum.—E. **Brylinski**: On a possible thermal perturbation in Michelson's experiment.—Nicolas **Perrakis**: A remarkable property of the first differential of the Trouton-de Forcrand law and on the probable value of the electronic entropy.—T. **Batuecas**: Revision of the compressibility of methyl oxide and the molecular weight of this gas. The pressures exerted by a given mass of methyl ether were measured at five volumes, the results being expressed in the form $pv = a - bp$. From the density of the normal litre previously determined and the coefficient obtained from these experiments, the figure 11·999 is deduced for the atomic weight of carbon. This result proves that the law of limiting densities is rigorously applicable in all cases, provided that the variation of the compressibility with the pressure is taken into account.—L. **Locoste**: Microseismic movements at Strasbourg. It is shown that there is a relation between the microseismic movements and meteorological conditions (variations of barometer and of wind velocity).—Alfred **Carpentier**: The fructifications of the Pteridospermeæ from the Westphalian of the North of France.—**Bezssonoff**: The colour reactions of the liposoluble factors. A study of the colour reactions produced with phosphomolybdotungstic acid.—F. **Vincens**: Possibility of the transmission of pernicious *loque* of bees by the grubs of *Galleria mellonella*.—E. **Lesné**, R. **Turpin**, and Ch. O. **Guillaumin**: Some physico-chemical variations of the plasma during conditions favouring convulsions in the child.—Marc **Romieu**: Microchemical studies on the granulations of the eosin-fixing leucocytes in man.

ROME.

Royal Academy of the Lincei; papers submitted during the Vacation, 1924.—G. **Ricci-Curbastro**: Varieties in equal principal invariants.—M. **La Rosa**: The Doppler effect and the ballistic principle in relation to the velocity of light. A reply to a note by W. De Sitter.—A. **Angeli**: Constitution of santonin. The compounds resulting from the gradual decomposition of santonin by means of dilute aqueous permanganate are described.—Ferruccio **Zambonini**: Atomic structure according to Bohr, and the isomorphogenism of metals of the rare earths with those of the calcium group.—Giuseppe **De Lorenzo**: Coal in the mesozoic strata of Lagonegro in Basilicata.—P. Vinassa **de Regny**: The mesozoic region of Central Dancalia.—Francesco **Tricomi**: Numerical resolution of Fredholm's integral equations.—O. **Mayer**: Transformations between linear elements of two surfaces which retain Levi-Civita's parallelism.—G. **Cassinis**: Gravimetric comparison of Rome with Bologna and Padua. If the value of g is taken as 980·367 cm. at Rome, the corresponding values at the University of Bologna and at the Royal Astronomical Observatory at Padua are respectively 980·455 and 980·659 cm.—Franco **Rasetti**: Effect of the magnetic field on the polarisation of resonance radiation. The results of experiments with mercury vapour are described, and the known facts are shown to be capable of simple correlation and to be intimately connected with the Zeeman effect and with the orientation of the atoms in the magnetic field.—A. **Cruto**: Chemical constitution of insulin. The empirical formula of highly purified insulin confirms the classification of this substance with the proteins, and, in conjunction with its reactions, indicates for it a position among either the globulins or the albumoses.—G. **Mazzetti**: Thermal dissociation of certain carbonates. The means adopted in the study of these dissociations consisted of thermal analysis and of an arrangement permitting the curve connecting the temperature with the diminution in weight to be traced directly on a photographic plate. Certain of the values obtained for the temperature of initial decomposition differ from those given by previous investigators.—V. **Tognazzi**: Chalkones and hydrochalkones. In alcoholic solution and in the presence of platinum black, each of the chalkones examined absorbs two atoms of hydrogen, yielding the hydrochalkone.—Carlo **Cappelletti**: The vegetation of resins. The fungi found in resins are nourished by the impurities always extruded with the resins and are able to tolerate oil of turpentine in relatively high proportions. In a moist climate the slow drying of the resin encourages the establishment of the fungoid vegetation, whereas in a dry climate the resin undergoes rapid superficial drying, invasion of the mycelia being thus checked.—P. **Pasquini**: Further knowledge of the pelagic fauna of Lake Trasimeno.—U. **Pierantoni**: New observations on luminescence and symbiosis. III. The luminous organ of *Heteroteuthis dispar*.—M. **Sella**: Observations on the innervation of the myotome of the murenoids and other Teleostei.

CAPE TOWN.

Royal Society of South Africa, August 20.—Dr. A. Ogg, president, in the chair.—S. H. **Haughton**: A bibliographic list of pre-Stormberg Karoo reptilia with a table of horizons.—G. W. **Cox**: On the periodicity of rainfall. A cursory inspection of any table of annual rainfall values discloses irregularities which suggest the results of pure chance. A vital question in long range weather forecasting is whether the values of data follow any law of succession separable from the law of chance. This paper discusses the existence of a cycle in rainfall.

Official Publications Received.

Bureau of Education, India. Pamphlet No. 18: Conference of Indian Universities held in May 1924 at Simla. Pp. viii+79. (Calcutta: Central Publication Branch.) 7 annas; 8*d*.

Diary of Societies.

MONDAY, OCTOBER 27.

CAMBRIDGE PHILOSOPHICAL SOCIETY (Annual General Meeting), at 4.30.—J. T. Saunders: The Hydrogen in Concentration of the Waters of Lake Lucerne.—J. Gray: The Process of Cell Division in the Eggs of Echinoderms.—V. Nath: Oogenesis of Lithobius.—*By title only*:—Dr. H. Singh Pruthi: Studies on Insect Metamorphosis—1. Prothetely in Mealworms (*Tenebrio molitor*) and other Insects. Effects of Different Temperatures.—H. Munro Fox: Chlorocruorin.—C. G. F. James: Characteristics of Complexes of Conics in Space of Four Dimensions.—T. M. Cherry: Integrals developable about a Singular Point of a Hamiltonian System of Differential Equations.—R. A. R. Tricker: A Helical Method of focussing β-rays.—D. R. Hartree: Some Methods of estimating the Successive Ionisation Potentials of any Element.—Sir Joseph Larmor: Why Wireless Electric Waves can bend round the Earth.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—Prof. F. O. Bower: Presidential Address.

INSTITUTE OF ACTUARIES, at 5.—A. D. Besant: Presidential Address.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—W. B. Woodhouse and others: Discussion on The Interconnexion of Power Stations.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre), at Armstrong College, Newcastle-on-Tyne), at 7.15.—W. T. Macca Chairman's Address.

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—J. G. Turn Presidential Address.—E. D. D. Davis: Some Points in the Patholo Diagnosis, and Treatment of Disease of the Maxillary Antrum.

MEDICAL SOCIETY OF LONDON, at 8.30.—Clinical Evening.

TUESDAY, OCTOBER 28.

ROYAL DUBLIN SOCIETY (at Royal College of Surgeons, Dublin), at 4.15. H. H. Jeffcott: The Determination of the most Economic Size of Pipe Li for Water Power Installations.—Dr. W. R. G. Atkins and G. T. Harri Seasonal Changes in the Water and Heleoplankton of Fresh Wat Ponds.—K. C. Bailey: The Synthesis of Urea from Carbon Dioxide a Ammonia under Atmospheric Pressure.—Miss S. D. King: Oogenesis *Lithobius fortificatus*.—A. Subba Rass, F. W. R. Brambell, and Prof. B. Gatenby: Observations on the Golgi Bodies in the Living Cell.

INSTITUTION OF CIVIL ENGINEERS, at 6.—E. Crammond: The Economi Position of Great Britain.

INSTITUTION OF AUTOMOBILE ENGINEERS (at 83 Pall Mall) (Informal Mee ing), at 7.—Demonstration and Discussion of Devices connected wit Cars not yet on the Market.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Special Gener Meeting (Members only).

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at Elmbank Crescent, Glasgow), at 7.30.—Discussion on Paper by A. J. Taylor: Pulverised Fuel in its Commercial Aspect.—E. F. Spanner A Proposed Form of Bow Construction.

WEDNESDAY, OCTOBER 29.

INSTITUTE OF PHYSICS (at Institution of Electrical Engineers), at 5.30.—Sir Oliver Lodge: Electrical Precipitation ("Physics in Industry, No. vii.).

THURSDAY, OCTOBER 30.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—Major J. S. Buchanan: The R.Ae.C. Light Aeroplane Competitions.

SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section and Faraday Society) (at University College, Nottingham), at 5.30.—Dr. W. L. Bal and others: Discussion on Textiles.

CHILD-STUDY SOCIETY, at 6.—Dr. H. Y. Trotter: The Teaching of Music.

SOCIETY OF DYERS AND COLOURISTS (Midland Section) (at University College, Nottingham).—N. C. Lamb: The Dyeing of Leather.

INSTITUTION OF LOCOMOTIVE ENGINEERS (at Engineers' Club, Coventry Street, W.), at 7.—J. E. Anderson: Presidential Address.—Sir Henry Fowler: Solid Crank Axles for Locomotives.

FRIDAY, OCTOBER 31.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Anatomy and Malformations of the Heart—(3) Specimens illustrating Points in the Applied Anatomy of the Human Heart.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—Discussion on Engineering Novelties at the British Empire Exhibition.

INSTITUTION OF MECHANICAL ENGINEERS (Leeds Section) (at Leeds).—Prof. W. T. David: Heat Loss in Gas-Engines.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section) at 7.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Kinematograph Group), at 7.—L. Eveleigh: Professional Secrets and Trick Kinematography.—J. Noble: Out of the Ink Pot and how it is done.

JUNIOR INSTITUTION OF ENGINEERS (at 39 Victoria Street), at 7.30.—H. J. N. Riddle: Audio-frequency Transformers.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Graduate Section) (at Cleveland Institution, Middlesbrough), at 7.30.—L. W. E. Rowbotham: Chairman's Address.

SATURDAY, NOVEMBER 1.

GILBERT WHITE FELLOWSHIP (at Queen Square, W.C.), at 3.—Sir A. Daniel Hall: The Countryside in English Literature (Presidential Address).

PUBLIC LECTURES.

SATURDAY, OCTOBER 25.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—F. Balfour-Browne: Social Life amongst Insects—(1) Ants, Bees, and Wasps.

MONDAY, OCTOBER 27.

UNIVERSITY COLLEGE, at 5.30.—Sir Mark Hunter: The History of English Pronunciation.

WEDNESDAY, OCTOBER 29.

UNIVERSITY COLLEGE, at 5.30.—L. Newcombe: University College Library and Modern University Libraries.

FRIDAY, OCTOBER 31.

UNIVERSITY COLLEGE, at 5.15.—Lt.-Comdr. A. S. Elwell-Sutton: China, her People and the Present Situation.

SATURDAY, NOVEMBER 1.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Some Famous Pharaohs.

Popular Science Exhibitions.

NOW that the British Empire Exhibition has come to an end—for this year at any rate—it may be of interest to record some impressions of the manner in which the Royal Society's Exhibition of Pure Science, which was arranged in the Government building, has appealed to the public, and of the extent to which it has fulfilled the objects with which it was organised.

The arrangement of this exhibition was undertaken by the Royal Society, at the request of the Government, for the purpose of showing the essential part played by pure science among the multifarious interests and activities of the Empire. Everywhere in the great Exhibition the applications of science to industry were to be seen, but the fundamental work of scientific inquiry, in which many of them had their origin, would have been unrepresented unless some special effort had been made to bring it to the public notice. Accordingly, this exhibition, illustrating many aspects of purely scientific research at the present time, and indicating how industry has developed from similar inquiries in the past, was arranged.

The exhibition has not been without its humours. One was the difficulty of returning a satisfactory answer to the inquirer who, after spending some time in the galleries, said, "Yes, but how do you know there is an atom, and how do you know there are electrons inside it?"; and another, the problem presented by a visitor who, on observing that the Milne-Shaw seismograph has a rotating drum giving a record which has to be changed every twenty-four hours, asked, "What happens if there is an earthquake while you are changing the record?"

Nevertheless, it may be said that the exhibition has been an unqualified success. The public, non-scientific as well as scientific, has been really interested, and some, at least, must have gone away with a clearer understanding of the purposes for which men devote their lives to scientific experiment and inquiry. This success may be attributed largely to the policy adopted of making the exhibition a living one. The exhibits were contributed by scientific workers actually engaged in the researches represented, and supplemented, where necessary to illustrate a subject fully, by instruments contributed by some of the leading makers. Wherever possible, actual demonstrations were given, and a scientific staff was in attendance throughout to carry out the demonstrations and to explain the exhibits. This policy was fully justified by the continued interest of visitors.

The Handbook published in connexion with the exhibition has been of great assistance. In this book is

made available, for the small cost of a shilling, a series of non-technical articles on current scientific topics by leading authorities; and the best proof of its popularity is the fact that more than two thousand copies were disposed of, while its sale is increasing as it becomes better known, and is likely yet to continue now that the Exhibition is closed.

The encouraging success which has met this attempt to present pure science in a less austere light than often surrounds it in the eyes of the general public, leads naturally to the inquiry as to whether a greater use cannot be made of scientific exhibitions as a means to this end. Nothing but good can result from such efforts to spread a clear understanding of the true aims and purposes of science. That pure science is the modern expression of the elementary desire for knowledge—for the discovery of natural truths—that it is only by the disciplined quest in unknown fields that those benefits which science gives to the human race can accrue, is too little understood and too easily lost sight of, because of the very magnitude of the results themselves.

It ought to be possible to make an exhibition of this kind an annual event. The Scientific Products Exhibitions, organised by the British Science Guild in 1918 and 1919; the Scientific Novelties Exhibitions held at King's College, London, in connexion with the King Edward's Hospital Fund in January 1923 and 1924, and experience at Wembley show that such displays of scientific work and results are much appreciated by the public. The desire for truth is at least as strong and as laudable an inspiration to the human spirit as the desire for beauty, and an event of this kind might well become to the world of science what the annual exhibition of the Royal Academy is to the world of art.

Such an annual exhibition would serve to maintain interest in the work of scientific inquiry, and help to keep it in the public mind in its just relation to the other activities in life. To men of science it might become a valuable auxiliary to the usual methods of publication of new scientific work, by reaching a wider public than the transactions of the scientific societies or the scientific periodicals can ever hope to do; and to the museums, it could be a source from which to obtain objects of interest from time to time, and thereby do much to prevent such national misfortunes as, for example, the dispersal, during the War, of the apparatus used by H. G. J. Moseley in his historic work on the X-ray spectra of the elements. It is to be hoped, therefore, that whatever facilities or funds are required to secure the continuance of the pure science exhibits and demonstrations now at Wembley will be provided.

Archæology of Stonehenge.

The Stones of Stonehenge: a Full Description of the Structure and of its Outworks. By E. Herbert Stone. Pp. xv+150+36 plates. (London: Robert Scott, 1924.) 21*s.* net.

MR. STONE is to be congratulated on having written a book which has long been wanted for giving a good up-to-date description of Stonehenge. He has gone very thoroughly into the subject, viewing it from all points, describing the arrangement of the stones, their source and geological nature; also a great many little items of particular interest which the monument and the site afford, and they are very well illustrated by photographs and drawings. Being a civil engineer and of much experience, his profession has taken him to places and amongst primitive people where he was able to note ways and means of working stones analogous to those at Stonehenge, so he is well qualified to give a description. This will be seen in the chapter on quarrying, where he mentions and illustrates methods in use in India comparable with those employed by neolithic man, and a stone maul can be seen in one photograph which is identical with those found at Stonehenge.

To gain a greater knowledge of this subject, Mr. Stone has experimented upon actual Sarsen boulders derived from the source the Stonehenge Sarsens were taken from. He has culled the best information from modern archæology and gives also the opinions and accounts handed down to us from early pioneers, some of them rather impossible views, but amongst them a certain amount of good reasoning which the reader may find pleasure in sifting. He also quotes the account of the foreign stones given by Dr. Thomas, whose long and patient search for their source was rewarded by finding all the Stonehenge varieties at one locality in Pembrokeshire, putting beyond doubt the source of their origin.

The author is at his best as an engineer when he explains a simple method of erecting the stones, which, if not exactly similar in all details, must approach very nearly the one employed by the builders. He calculated with precision the weights and strains and the forces necessary for movement, and has shown by actual experiments carried out by himself how primitive people, with simple contrivances, could handle massive stones and set them up with great accuracy and with comparatively little labour. Thick raw-hide ropes no doubt would have been used, and their great tensile strength can be judged when remembering what a strain an ordinary violin string can endure. The chapter devoted to this account of engineering skill will certainly be read with great interest.

The author is in error over a fallen foreign stone h figures in Plate 6, Fig. 2, in supposing the holes seen on it were made, after it had fallen, Romano-British people for grinding corn, first, use the cupped holes would be too small, and adly, because the stone is evidently a lintel. It irved in the same way as are those of the outer e, but in this one the curve is sharper, showing elonged to something smaller. The holes in the e are equidistant from the ends and are dowe s like those in the big lintels, and this stone may nerly have fitted over the terminal upright stones he horseshoe. It is unlikely that a Romano-ish peasant would have gone to the arduous task aking holes in a stone so hard when querns could asily procured. That this was so is evident from great quantity of broken querns found in British ges; even those of Andernach lava are fairly mon, and no doubt were brought in the finished e by hawkers and perhaps by the same route as Romano-Gallo ware.

love for mathematics and careful measurements have prompted the author to become interested Sir Norman Lockyer's conclusion that the place been laid out on astronomical lines. He has lently studied the subject very carefully, and his osition of it is of decided interest. It has been bitterly controversial subject amongst archæo-sts, but is nevertheless one which cannot be lightly sed over, for there are certainly some points in which are well worthy of consideration. The tention has been that Stonehenge is sepulchral, ause stone circles and dolmens almost invariably lter the dead, and that they do may be taken for nted.

Recent research at Stonehenge makes it appear ond doubt that the site on which it stands has had ng history, and certain appearances have come to t of changes of building anterior to the present nument. The ditch is extremely primitive and l within neolithic times. It was certainly defensive, there is a palisade at the entrance, and at that e it would be secular, sheltering a little community der a much-respected chief. When he died he uld have been buried, possibly under a dolmen in middle of the enclosure, and a circle of stones cted within the rampart. It would then have come sacred, and the ditch, no longer wanted, would allowed gradually to silt up. After a long lapse years, and for some unknown reason, it was decided erect Stonehenge, and to do so the dolmen and cle disappeared. Whether the neolithic inhabitants the country decided amongst themselves to do this, were prompted to it by the advent of a foreigner, it is impossible to say, but the latter idea is the more probable, and although incapable of such a conception themselves, they would willingly do the work from tuition.

It is quite evident that the place was not a first attempt at building, and must have been designed by a master mind and a great engineer who had had much previous experience. He probably came from the south, and may even have participated in megalithic work in Egypt, though not an Egyptian. Under his careful guidance and drilling, and perhaps rehearsal of the work, he made the people do all he wanted. Whether or not he had acquired all the knowledge of the Egyptians one cannot say, but he must have been able to make an elaborate plan in laying out the place, and to calculate with fair accuracy the weight of stones and strain upon ropes, and other mechanical details.

Every one seems to be agreed that Stonehenge is definitely orientated towards the north-east, but the chief question is whether it was built entirely for sepulchral use. Probably it was not, because, having been previously a sepulchral spot, it is scarcely likely they would interfere with the buried remains and replace them with those of another person. It would preserve its sanctity because of the previous burial and be combined with the purpose for which it was erected. If that, or one of the purposes, was for determining the beginning of a particular season of the year, no very precise astronomical knowledge would be necessary, and it might well have been used for this purpose. A building so unique would command fame and reverence, making it a centre for the gathering of headmen of tribes to settle their important matters. No interment belonging to the period it represents has yet been found; cremated remains that have occurred belong to the Bronze Age, and therefore later in date, show that although it may have been secularised it still retained a sacred significance to a later race. The east and west stones on the rampart have not yet been archæologically explained, and one which was examined did not appear to be for sepulchral use.

The author has admirably expounded his theory in the chapter devoted to it, and even those who disagree with the astronomical theory will find much matter for careful consideration. Whether the research when concluded will throw more light upon the matter cannot be foretold, but when all is said and done there will yet be questions which will elicit the answer, "We do not know."

The book will prove interesting and instructive, not only to students of archæology, but also to all who take an interest in Stonehenge.

Rhododendrons.

Rhododendrons and the various Hybrids. By J. G. Millais. Second series. Pp. xii+264+53 plates. (London: Longmans, Green and Co., 1924.) 210*s.* net.

IT says much for the hold rhododendrons have secured in the estimation of horticulturists that Mr. J. G. Millais was so much encouraged by the success of his first work on the genus in 1917 as to prepare and publish a second volume of the same sumptuous character as its predecessor. The cost of the two volumes amounts to eighteen guineas, and there is certainly no other genus of trees or shrubs in which public interest is sufficiently strong to render possible the profitable issue of such volumes as these.

Whilst no genus of shrubs is so popular at the present time as Rhododendron (including, as it does, Azalea), that popularity is by no means a new one. Since the middle of last century at least, rhododendrons have been regarded as one of the most essential elements of the open-air garden. No rhododendron is indigenous to the British Isles, and only some half-a-dozen to the whole of Europe, the best known of which are the two species so abundant on the mountains of Central Europe—the so-called "Roses des Alpes." In 1736 *R. maximum* was introduced from the mountain summits of the Carolinas and Tennessee; in 1763 *R. ponticum* was brought from the Pontus region in Asia Minor; and between that date and 1809 were acquired for English gardens *R. caucasicum*, *R. catawbiense*, and *R. punctatum*. By this date also three species of the deciduous-leaved or Azalea section had reached Great Britain, namely, *R. viscosum* and *R. calendulaceum* from North America and *R. flavum* from Asia Minor. It was to these comparatively few species that the labours of the hybridists of one hundred years ago were necessarily confined. The range of colour amongst the evergreen species was a narrow one and extended only from white to pink and purple, but in 1825 *R. arboreum* from Northern India produced for the first time its blood-red flowers in Britain and thereby added a new and very valuable pigment to the hybridiser's palette. It may indeed be truly said to have completed the group of species from which the common type of garden hybrid rhododendron as we knew it up to twenty or thirty years ago was almost entirely derived.

Sir Joseph Hooker, during his famous journeys in the Himalaya (1847–1851), especially in Sikkim, sent home seeds of practically all the species native of that region, but most of them are only hardy in the southern and western maritime counties of England, and it was not until the 'eighties of last century that their "blood" began to show in the hardier hybrids. But now some of the best hardy varieties owe their meri largely to what they have inherited from *R. Aucklandi barbatum*, *Thomsonii*, and *ciliatum*. The Himalaya species may be said to have initiated the second phas in the development of the modern garden rhododendron

The third and contemporary phase is bound up almos entirely in the exploitation of the flora of Wester China and Tibet, which we owe in the main to fou British collectors, namely, Wilson, Forrest, Kingdor Ward, and the late Reginald Farrer. Wilson's travel in China ended in 1910, and the rhododendrons he intro duced were fully dealt with in Mr. Millais' first volume The new volume is for the most part concerned with the work of the last three collectors, of whom George Forrest is much the most prominent. Mr. Millais cal culates the number of species of rhododendron now known to be about 670, about 300 of which have been brought to the knowledge of botanists by that collector

In assembling in one volume full and adequate descriptions of all the new species published up to the present time, Mr. Millais has rendered a very valuable service to rhododendron lovers. The arrangement is alphabetical, but the student is helped by being told the "series" to which each species belongs, and in that way is given a useful lead towards visualising its genera character. As a matter of fact, the genus is in a rather chaotic state at present. Species have been described in large numbers, many on very trivial differences, but no serious attempt has yet been made to co-ordinate them. The influx of new material is still going on, so perhaps the time for that is not yet.

Mr. Millais' book contains a good deal more than mere descriptive matter. He commences with a dissertation on shrub gardening in general, which, although somewhat outside the main theme, is extremely interesting and useful. That there is no one better qualified to discourse upon it, all who know Mr. Millais' own charming garden at Horsham will cordially agree. A valuable chapter on Chinese rhododendrons and the work of Forrest, Ward, and Farrer contains much original information supplied by the collectors themselves about rhododendrons as they were seen growing in their native habitats and the conditions under which they exist.

There is nothing rhododendron growers are more keen about than hybridisation. So many wonderful results have been obtained in the past that one cannot be surprised at that. Hybridising these shrubs is not unlike the labours of the old-fashioned gold miners. Conducted on well-reasoned lines, one may always be sure of obtaining something good, with the possibility of an occasional large nugget such as the late Sir Edmund Loder secured in *Rhododendron Loderi*. The author's useful résumé of the work done by prominent

ers during recent years will be read with much
e st. A chapter on cultural matters concludes the
r luctory part of the work.

M Millais is to be congratulated on the successful
plishment of a very arduous task. He has
ht together very nearly all the knowledge about
dendrons that really matters — which is a great
r to have done. Handling his book, one could wish
imes that it were not so large, but then we should
missed the fine coloured pictures by Miss Beatrice
ns and Miss Winifred Walker. Other coloured
s by Miss Snelling are excellent, and besides all
he book is lavishly illustrated by reproductions
photographs of plants both wild and cultivated.

W. J. BEAN.

The Origin of Solubility.

ility. By Prof. Joel H. Hildebrand. (American
emical Society Monograph Series.) Pp. 206. (New
rk: Chemical Catalog Co., Inc., 1924.) 3 dollars.

O a reader who has not followed recent American work on solubility, the contents of Prof. Hildebrand's book provide a pleasant surprise. Instead of a compendium of data, there is here a real attempt to develop a general theory of solubility, and of the wider problems of miscibility in liquids, and of the properties of the resulting mixtures. The starting-point of this general theory is not the familiar Law of Osmotic Pressure of van 't Hoff, but the more fundamental Law of Vapour Pressures of Raoult. Thus, in the case of certain mixtures, Raoult's law is valid over the whole range of concentrations from 0 to 100 per cent., whereas van 't Hoff's law is limited to dilute solutions and, even when modified, cannot be extended in a similar way. An ideal solution is therefore defined as one which obeys Raoult's law at all temperatures and pressures. This depends on the internal forces remaining undisturbed on substituting molecules of one kind for molecules of solvent. The author discusses what are the properties of the individual liquids, the stability of which is likely to lead to this result, and concludes that equality of "internal pressure" is the most important factor. Moreover, if this condition is fulfilled at one temperature and pressure, it is likely to be realised over the whole range.

Deviations from Raoult's law are of two types. "Negative" deviations are accompanied by a contraction and evolution of heat on mixing, and may be accounted for, at least in some cases, by the formation of unstable compounds of solvent and solute. "Positive" deviations, accompanied by an expansion and absorption of heat on mixing, are less easily explained. In general they could be accounted for by the *association* of one of the pure liquids, so that dilution with an inert solute would give rise to *dissociation*; but, when this is regarded as the only possible explanation, it leads to the assumption of polymerised molecules of argon in solution in liquid nitrogen, and in general to the necessity for assuming an altogether unreasonable degree of molecular complexity in order to account for the larger deviations. Positive deviations from Raoult's law can also be "explained" by the existence of wide differences in "internal pressure," but this is in a sense little more than a paraphrase.

The author is, however, considerate enough to give a simpler (if less rigidly proved) explanation, by using the familiar classification of liquids into (i) "normal" liquids with low dielectric constants and small residual fields of force round the molecules, and (ii), "polar" liquids with high dielectric constants and large or unsymmetrical fields of force. The polar molecules, he says, have an abnormally great attraction for each other, thus producing greater cohesions, internal pressures, surface tensions and heats of vaporisation. They therefore tend "to squeeze out, as it were, non-polar or slightly polar molecules from their midst"; and on account of this selective attraction of the polar molecules for each other, "the squeezing-out effect may be greater than it would be in the case of high internal pressure alone, unaccompanied by polarity." The result is a strong positive deviation from Raoult's law, with a corresponding influence on solubility. This classification is, of course, not a rigid one, but it agrees well with the familiar experience of all chemists that "if substances are divided into two groups, polar and non-polar respectively, those within either group are usually most soluble in the other substances within the same group and least soluble in those of the other group."

The summary given above of some of the points discussed by the author would probably give quite a wrong impression of the book, by suggesting that it is qualitative and non-mathematical in character. It may be taken as an unsolicited testimonial to the skill of the author that it should be possible to deal in this way with a book that is rigidly thermodynamical in its method of treatment. He has, indeed, written in such a way that a reader who is unskilled in thermodynamics and who "funks differentials" can nevertheless follow his argument with comfort. Such a reader is permitted to shut his eyes whilst traversing the thermodynamic tunnels, in the expectation that he will soon emerge, not merely into the daylight of an open cutting, but into broad stretches of open country. The book is therefore one that is well worth reading, and the author is to be congratulated on his success in presenting a difficult subject in so attractive a form.

T. M. L.

Hydrodynamics.

Hydrodynamics. By Dr. Horace Lamb. Fifth edition. Pp. xvi + 687. (Cambridge: At the University Press, 1924.) 45*s.* net.

LAMB'S text-book has long been the chief storehouse of information of all workers in hydrodynamics. One may note that the interval between the first and second editions was 16 years, and that successive editions have followed at intervals of 11, 10, and now 8 years respectively. Perhaps the steady decrease is to be attributed to the development of interest in the subject, which has during the last ten years come into closer relation with experience than the most optimistic student could have anticipated previously. In any case, the fifth edition is welcome, for it contains not only all the good features of its predecessors, but also most valuable accounts of recent discoveries. Dr. Lamb's alertness to modern advances may be estimated from the fact that ten entries relating to Prof. G. I. Taylor occur in the index. Abundant references to original papers are given in the footnotes.

A new section (91*a*) gives a short account of the expansion of a spherical cavity in water due to an internal explosion, and of the collapse of an exhausted cavity. Section 159*a* deals with the two-dimensional motion of solids in a liquid with uniform vorticity. Section 205*a* gives a new theorem relating to small oscillations of a gyrostatic system about a steady motion. Rayleigh proved that the normal modes of vibration of a non-gyrostatic system were those that made the periods stationary for small variations in the adopted ratios of the co-ordinates. Lamb here proves the corresponding theorem for a gyrostatic system.

The account in Section 284 of the propagation of a wave of discontinuity in air has been much improved by the inclusion of a discussion of the modification introduced by conduction, with an estimation of the extent of the region of transition. Section 330*a* describes the theory of a case of lubrication. In Section 334*a* several cases of the transference of momentum in a viscous fluid in a non-steady state are worked out, and also the theory of the maintenance of an ocean current by a steady wind blowing over the surface. The effect of porous bodies in absorbing sound is discussed in Section 360*a*. A few simple cases of turbulent motion are treated in Section 366*a*, *b*, and *c*. The nature of the theory of the motion of solids in a real fluid is outlined in Section 372*a* and *b*. A new section at the beginning of the chapter on rotating masses of fluid gives proofs of the theorems of Poincaré and Lichtenstein on the possible modes of rotation of a fluid mass. Two slips of the pen which have be noticed are, on p. 643, $2{\cdot}2 \times 10^{19}$ is printed instead $1{\cdot}1 \times 10^{19}$, and, on p. 648, $-\omega^2 z$ appears instead of for the z acceleration.

A few remarks concerning Dr. Lamb's use of t reversed sign for the velocity potential may not be o of place. He justifies this course on two ground First, it gives the velocity potential the same sign as t impulsive pressure needed to start the motion; secon it completes analogies with other branches of math matical physics. Neither of these arguments appea to the reviewer to have much weight. From analo with elasticity, where the positive stress and strain bo correspond to an extension, an impulsive tension appea to be a more suitable standard than an impulsi pressure, and the velocity potential without reversal h the same sign as the impulsive tensions. The use pressure instead of tension in hydrodynamics aris from the fact that it is usually (though not always) t pressure that is positive in fluids; the adaptation of t sign of the velocity potential to this fact tends obscure the physical analogy between elasticity a hydrodynamics. Again, while the reversed sign agre with the usual practice in electrostatics, it disagre with that usual in gravitational theory, which is mo closely associated with actual hydrodynamic problem In each of these cases the current convention has be adopted purely in order to reduce the number of tim the minus sign has to be written; which is in itse a reason for not reversing the sign of the velocit potential. H. J.

Psychical Research.

Experiences in Spiritualism with D. D. Home. E the Earl of Dunraven. Pp. iv+285. (London Society for Psychical Research, 1924.) 7*s.* 6*d.*

THIS book ought to have been published long ag In a way indeed it was, to wit in 1870, but onl for private circulation, on account of the violer prejudices which its subject then excited both i religious and in scientific circles. It is a record of t marvels which seemed to those present to happe in connexion with D. D. Home, the most famou "medium" of modern times, and is composed mainl of reports, written by the present Earl of Dunraver then Viscount Adare, to his father, on seventy-eigh sittings with Home in the years 1867–69; but in te cases the notes were taken by the late Earl, who als wrote an introduction. The present Earl has now r printed the material and equipped it with a prefac and with a lucid and temperate introduction by S Oliver Lodge; but he has not attempted to fill in th

which were left in the evidence where matters considered too intimate for publication. After a of more than fifty years, most of these could surely been filled in without offence, and thus have teracted the attenuating effect which the mere of time has on the scientific value of any historical native. Nor is the recording itself as full and expert rookes's account of his experiments with the same ium.

evertheless, Lord Dunraven has put under a obligation all students of the secular struggle een the champions of "law," convention, pre-ce, scepticism, conservatism, on one hand, and of t," eccentricity, open-mindedness, credulity, re-tion, on the other. The continuance of this ggle is due to the fact that the progress of know-e demands a co-operation of both these tendencies, hat neither can lay exclusive claim to the term entific"; while the question as to which party is t cannot be settled by any appeal to general iciples, but only (if at all) by patient and prolonged mination of each case.

ll this applies with peculiar force to "spiritualism," h excites strong emotions on both sides, and dis-s a dramatic clash between established principles subversive testimony. But it would be utterly ientific to burke investigation on this account, r the fashion of Hume, by declaring that "miracles" alleged, and that miracles are impossible. This is e *a priori* dogmatism, which is discreditable alike hilosophy and to science.

may be that the times are not yet ripe for a y scientific inquiry into the facts alleged; certainly her party as yet welcomes examination. The man cience professes to be more interested in, say, the hridia of worms than in the immortality of his soul, le the spiritualist, though he rests his case on ervable facts, fights singularly shy of test conditions. n when a "medium" can be got to submit to mination, it is usually hard to find a man of science will conduct it; as was recently shown when, in e of a handsome salary, such a post went a-begging, il a physicist already compromised by interest in the ernormal accepted it, and speedily exploded a ous medium.

erhaps the truth of the matter is that both sides not quite sure of their ground and afraid to test r convictions. Still, one cannot read Lord Dun-en's book without feeling that progress is being le, though slowly; perhaps it is not too much to e that, in another fifty years, science will have n an explanation satisfactory to both the scientific ker and the spiritualist of the mysteries that are in dispute.

F. C. S. S.

Our Bookshelf.

The Morphology and Evolution of the Apes and Man. By Dr. Charles F. Sonntag. Pp. xi + 364. (London: J. Bale, Sons and Danielsson, Ltd., 1924.) 12*s.* 6*d.* net.

FULLY sixty years ago, Huxley systematised our knowledge of the anatomy and nature of anthropoid apes in a famous treatise to which he gave the title "Evidence as to Man's Place in Nature." Anatomists have been busy since then; there has been an enormous output of papers relating to the anatomy of apes, and there has grown up a great need for an ordered presentation and interpretation of the new material.

Dr. Charles F. Sonntag, Prosector to the Zoological Society of London, has stepped into the breach and sought to supply this need in "The Morphology and Evolution of the Apes and Man." This book, Dr. Sonntag informs us in his preface, "is intended to serve as an introduction to Anthropology, for it deals with the first steps in that science, namely the relations of Man to lower animals."

The scope of Dr. Sonntag's treatise is best indicated by citing the contents of its chapters. Chapter i. is devoted to a systematic account of lemurs and Tarsius, Chapter ii. to the New World monkeys, Chapter iii. to the Old World monkeys. Then follow nine chapters on the anthropoid apes. One is devoted to a description of their external characters, habits, and classification; then follow others in which plain accounts are given of their skeletons and teeth, of their muscles, of their organs of digestion, of their organs of circulation, of their respiratory systems, of their urino-genital systems, and of their nervous systems. In all of these chapters, Dr. Sonntag keeps his personal opinions in the background, being content to play the part of descriptive anatomist, leaving the interpretation of his facts to others.

In a final chapter a brief account is given of the evolution of the primates, the text of this chapter being greatly assisted by a clearly drawn phylogenetic tree. In this chapter, as in others, Dr. Sonntag is an eminently safe guide for both student and expert, for he has preferred to give a detailed account of the anatomy of apes, rather than to discuss the problems relating to their origin. Anatomists are indebted to Dr. Sonntag for this work, particularly for the full bibliography which is appended.

Institution of Petroleum Technologists. Standard Methods of Testing Petroleum and its Products. Pp. x + 102. (London: Institution of Petroleum Technologists, 1924.) 6*s.* net.

THE Committee appointed by the Institution of Petroleum Technologists to standardise methods of oil-testing has, under the above title, published its first report in the form of a concise manual. It was no easy task to criticise existing methods, to comment on relative advantages and disadvantages inherent thereto, to keep pace with current developments, and at the same time to issue an authoritative work formulating agreed methods of oil-analysis consistent with home and foreign procedures; but the Committee has

acquitted itself well. A compromise between methods dictated by custom, previous decrees of the British Engineering Standards Association, publications of the American Society for Testing Material and the American Bureau of Standards, has been achieved, to the lasting benefit of petroleum chemists and the industry in general.

Methods of testing oils and suitable apparatus are discussed, but the thorny problem of nomenclature has been left alone, owing to the impossibility of considering it on other than an international basis—a wise decision. Petroleum products are dealt with as gasoline, white spirit, kerosene, gas oil, lubricating oils, transformer oils, fuel oils, asphalt, and wax, and under each class appropriate tests are given, these tests being differentiated by "serial designations," *i.e.* reference letter to the class of product and serial number to the precise test. In the language of the Committee "I.P.T. Special Designation—G.O.4" will in future indicate the standard test for sulphur in gas oil (class G.O., test No. 4), implying the use of a bomb-calorimeter of approved specification with manipulation as prescribed; similarly for other products and their routine testing. No degree of finality of methods is achieved (nor was that desirable) in the report; the fabric on which the I.P.T. standardisation is built up is sufficiently elastic to permit of modifications and additions in technique demanded by future developments. H. B. MILNER.

The Journal of the Institute of Metals. Vol. xxxi. Pp. xi+680+40 plates. Edited by G. Shaw Scott. (London: Institute of Metals, 36 Victoria Street, Westminster, 1924.) 31*s.* 6*d.* net.

THE papers contained in the present volume are mainly of scientific interest. There are several studies of the equilibrium in binary and ternary alloys, including a remarkably well illustrated account of the alloys of copper and cadmium. Sir Henry Fowler gives a survey of the use of non-ferrous metals in engineering, and the president, Prof. Turner, devotes his address mainly to the importance of research in metallurgy. A practical investigation of the failure of some brass tubes, by Mr. Millington and Prof. Thompson, is chiefly interesting through leading the authors to a rather speculative, but highly ingenious, view of the mechanism of fatigue. The discussion on this paper shows how diverse are present opinions as to the nature of fatigue. A paper from Stockholm, partly covering the same ground as a recent communication from the National Physical Laboratory, treats of the study of inter-metallic compounds by means of X-rays. The volume contains a great deal of interesting matter, and, as usual, includes very full abstracts of the current literature relating to non-ferrous metallurgy.

Lunge and Keane's Technical Methods of Chemical Analysis. Second edition. Edited by Dr. C. A. Keane and P. C. L. Thorne. Vol. 1. Pp. xx+704. (London and Edinburgh: Gurney and Jackson, 1924.) 63*s.* net.

THE new edition of this important work is distinctly better than the earlier one. It is to be in six volumes, each complete with its own index (besides a general index for the whole series), and the contents have been rearranged so that associated subjects are grouped together more conveniently than in the first edition.

Dr. Keane has enlisted the assistance of British experts throughout, and certain of the sections, such as "Fuel" and "Cyanides," have been entirely re-written, while others are materially altered. The important sections on sulphuric acid, chlorine, and alkali have been brought up-to-date by Dr. J. T. Dunn. Dr. J. S. G. Thomas is responsible for "Gas Analysis" and for a noteworthy new section on "Physical Methods," while a new chapter on "Electrolytic Methods" is excellently dealt with by Dr. H. J. S. Sands.

Very few printer's errors have been observed, and except for a few of the illustrations, the book is well turned out. Altogether, this first volume represents a notable advance on the earlier edition, and it is to be hoped that the high standard will be maintained through the remaining volumes. T. W. H.

The Recent Development of Physical Science. By William Cecil Dampier Whetham. Fifth edition. Pp. xvi+313+16 plates. (London: John Murray, 1924.) 9*s.* net.

TWENTY years ago, Mr. Whetham wrote a remarkable book, in which he gave, in pleasant narrative form, an account of the discovery of the electron, and other matters which were then new in physical science. The mobile electron has moved a long way in twenty years and as a result nearly half of the new version of the book is devoted to describing ideas and facts which had scarcely come into existence when the first edition was issued. It would, however, be an injustice to suggest that Mr. Whetham has limited himself to telling, as so many others in recent years have done, the story of the electron and nothing else. Just as the earlier work included chapters on the liquefaction of gases, and on the processes of crystallisation from fusion or solution, so the later additions include a chapter on "Matter, Space and Time," under the appropriate motto "Oh, dear! What can the matter be?" and a chapter on astrophysics. On account of its breadth of treatment, the book can be commended to readers who hold that neither the naked ion of thirty years ago, nor the naked electron of to-day important as they are, can claim a complete monopoly of interest in physical science.

Technical Writing. By T. A. Rickard. Second edition, re-written and enlarged. Pp. ix+337. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1923.) 10*s.* net.

THE second edition of Mr. Rickard's book has been thoroughly revised and enlarged. It is a useful guide to the writing of technical papers, and, although the worst examples of faults to be avoided are more often found in the technical press of the United States than in Great Britain, even a superficial student of publications on applied science must have noticed that such slovenly expressions are being increasingly used. The new sections include a chapter on "The Wrong Word," and another on punctuation. The sections on style are slight but sound, the aim of the author being to encourage clearness and simplicity in the statement of facts.

Letters to the Editor.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

Agricultural Research.

ON returning from a lecturing tour in Canada and the United States, I find among the files of NATURE "Cantab's" interesting letter in the issue of September 27.

I had no intention of being despondent in my address to Section M (Agriculture), nor is there reason for despondency. It is true that science has given only few aids to agriculture of the order of 100 per cent. increase in yield, but much has been done of a less spectacular nature, and agricultural experts are now able to advise farmers with considerably more certainty than was the case even thirty years ago. There have been great changes in practice, and science has helped considerably.

The history of agriculture shows that advances have come in three ways: from purely empirical methods tried by farmers with no definite scientific plan; from experiments on empirical lines made by trained workers: and from advances in pure science, whether initiated in a purely scientific, or, as has often happened, in a technical laboratory. It is a fact that in the past some of the biggest advances have been made by empirical methods, but one cannot infer that scientific methods are therefore inferior; only in recent years have they been adequately tried. Our knowledge of the biochemical changes in the soil, of the soil micro-organisms, the soil solution, and the soil colloids, quite apart from the theoretical work to which "Cantab" referred, has all come as the result of purely scientific work, done entirely with the view of gaining information, and with no idea of practical applications. Little of this knowledge is yet used in practice, for the simple reason that no one has found a way of using it, but history shows that the application comes sooner or later once the scientific discovery is definitely established. There is every reason to hope that agricultural science has fresh triumphs in store.

In recent years it has been easier to apply scientific methods in agricultural investigations because many of those responsible for the management of agricultural institutions, and especially the younger men, appreciate their value and realise the necessity for the so-called "academic work." No honest person working on scientific lines would ever commit himself to a definite promise that a particular investigation would have practical results; he can, however, so conduct it that it will yield sound knowledge. It is of course true, as "Cantab" points out, that epoch-making discoveries have not yet come direct from team work or directed research. But it must also be recognised that advances of this order are in any case very rare, and when they come it is largely as the result of the less spectacular, but none the less real, advances in knowledge which can be made in the well-equipped organised institution. No research institution can do more than hope for first order discoveries, but the staff can, at any rate, ensure good development work, and secure advances which in the aggregate count for much.

Like all other forms of research, agricultural research is finally limited by the state of knowledge of other branches of science; and a logical scheme of assistance would recognise the claims of all pure science. The present schemes may not be very logical, but knowing something of the methods by which a research institute has to be sustained, I am not sure that the departments of pure science have always adopted the best methods for obtaining assistance. A great difficulty of research institutions—and it must be far greater to the layman—is to know just what are the methods and the results of science, in other words, whether the limitation imposed by lack of knowledge in pure science lies in the man or the science. The agricultural investigator received his training in pure science it may be ten or twenty years ago; he tries to keep up, but is overwhelmed by the enormous and ever-increasing volume of papers of very varying merit and lucidity. The Chemical Society facilitates his task by issuing annual reports on the different branches of chemistry, but many other scientific societies have not followed this good example. There must be many papers in pure science buried in the libraries which would prove of great value to agriculture if they were known, but they are not. At Rothamsted we have adopted various devices for keeping in touch with pure science, one of the best of these being to bring young men and women from the purely scientific laboratories from time to time to take part in our work. This is one example of the "team work" to which I referred in my address as being among the hopeful ways of securing advances in agricultural science, another being co-operation between institutions engaged on different aspects of what may be fundamentally one and the same problem.

Team work makes it possible for the different workers to keep in touch, and to utilise advances made in other subjects. It has other advantages too, for even the wisest of mortals will never see a scientific problem as a whole, but only in part.

Rothamsted Experimental Station,
Harpenden, October 20.

Series in the Spectra of Aluminum and Magnesium in the Extreme Ultra-Violet.

PASCHEN (*Ann. d. Phy.* 71, p. 152, 1923), in his investigation of the spectrum of doubly ionised aluminum (Al. III.), and Fowler ("Series in Line Spectra," p. 120), in his study of ionised magnesium (Mg. II.), have pointed out the type of series relations which exist in these substances, and have arranged many lines to conform to them. In a study of the spectra of both aluminum and magnesium in the extreme ultra-violet, under various forms of excitation, I have recently observed certain lines which appear to be higher members of some of the series discovered by Paschen and by Fowler; Millikan has already identified the two strongest, but the remainder seem to have escaped observation. The wave-lengths and the series to which these lines belong are given in the following tables.

Al. III.

$3p - md.$			$3p - ms.$			$3s - mp.$

Mg. II.

$1s-m\pi$.		
Obs. λ Int.	Calc. λ	m.
1240·1 (4)	1239·9	2
1240·5 (4)	1240·4	
	1026·0	
1025·9 (2)	1026·1	3
946·6 (1)	946·7	4

The lines in aluminum were obtained with the vacuum spark and also with a condenser discharge in an atmosphere of helium at about 1 mm. pressure. The magnesium lines were most strongly excited by an arc of 40 volts and about 10 amperes operated in a high vacuum by means of a trembler device.

The numerical values of the wave-lengths should be correct to at least two-tenths of a unit.

It must be admitted that both Millikan and Simeon list a line at λ560·5 which they credit to carbon. The line at 1025·9 in magnesium might perhaps be ascribed to hydrogen were it not for the extreme weakness of the hydrogen line at λ1216.

The persistence of impurities, especially when high voltage excitation is employed, introduces uncertainties which cannot well be eradicated. But in my judgment, the structure of the spectra and the close agreement between observed and calculated values justifies the identifications shown in the tables.

THEODORE LYMAN.

Active Nitrogen.

PROF. M. N. SAHA and Mr. N. K. Sur, in an article which has just appeared in the *Philosophical Magazine* (48, 421, Sept. 1924), present a theory regarding the identity of active nitrogen which coincides in certain respects with that advanced by me last December, in a paper read before the American Physical Society (Abstract, *Physical Review*, 23, 294, Feb. 1924). Since this paper has not yet been published in full, and since there are important points of difference between the two theories, it seems advisable to present here certain of the details.

Active nitrogen was discovered in 1900 by Prof. E. P. Lewis (*Astro. Jour.* 12, 8, 1900) and was found by him to have a characteristic spectrum (*ibid.* 20, 49, 1904). It is now known without question, due to the work of Fowler and Strutt, that the α-group bands of this so-called afterglow spectrum are merely a few bands belonging to the First Positive Group of nitrogen, with, however, different relative intensity. The great majority of the bands of this group are definitely absent. Since we now know that all band spectra are due to molecules, and since various methods of investigation have proved beyond reasonable doubt that the First Positive Group is due to the neutral N_2 molecule, it follows inevitably that the emitter of the α-group bands is some form of the neutral N_2 molecule. In this letter I confine the term "active nitrogen" to the emitter of these α-group bands.

My investigation of the band spectrum of nitrogen, in the paper just mentioned, gave a partial indication of the exact form of the molecule responsible for this emission. The strongest band in each of the four groups forming the so-called α-bands corresponds, in the case of emission, to a transition from a molecular vibrational state indicated by the quantum number eleven. In a less accurate way we may speak of the molecule as possessing in the initial state eleven units of vibrational energy. The bands on either side of this strong band correspond to ten and twelve units. All other initial vibration states are entirely, or almost entirely, lacking.

It therefore seems evident, for reasons which will not be disclosed until we know the exact structure of the molecule, that the particular state of electronic excitation corresponding to the initial state of the molecule when emitting the First Positive Group bands, is *metastable*, for ten, eleven, and twelve (especially eleven) units of vibrational energy. The amount of rotational energy is seemingly immaterial. Saha and Sur do not assume a metastable condition, although to me this assumption seems vital. Active nitrogen is *formed* in the electric discharge, and then under the proper conditions diffuses out into a side tube where it may exist for some time (thirty seconds or more), *gradually* changing back to the ordinary nitrogen molecule with the emission of the α-group bands. Because of its excess energy, due to electronic excitation, it is chemically active, and in the presence of impurities it easily forms compounds or produces other excited atoms and molecules, as discussed by Saha and Sur, and also by Dr. Mulliken (NATURE, 114, 349, Sept. 6, 1924). Metastable conditions such as this are now commonly assumed to explain the origin of certain band spectra, such as the band spectrum of the helium molecule.

While the amount of vibrational energy in the active nitrogen molecule seems therefore known, the same statement cannot be made in regard to the amount of available electronic energy. The various major electronic energy levels of the neutral N_2 molecule, as calculated by the author, are given in Fig. 1, where the most stable state is on the right. These levels (X, A, B, C, and D) represent merely the electronic excitation, with no vibrational or rotational energy. B′ represents state B with the addition of eleven units of vibrational energy, where B′ − B = 17,148 (in frequency number). The frequency of the "origin" of the Fourth, Second, and First Positive Groups is thus represented by the lengths D − B, C − B, and B − A respectively, while the strongest bands in the α-group are represented

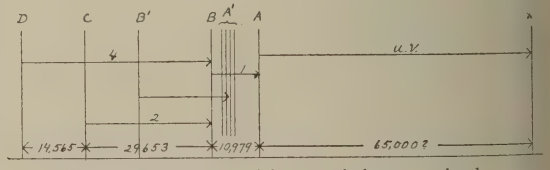

FIG. 1.—Energy levels of the neutral nitrogen molecule.

by B′ − A′, where A′ represents the A state with 9, 8, 7, and 6 units of vibrational energy, and correctly lies on both sides of B.

At the present time, experimental evidence points strongly to the conclusion that A is not the stable state of the molecule, but that there is another group of bands in the ultra-violet, connecting A with the true stable state X. It has not yet been possible definitely to identify such bands by quantitative agreement with the set of vibration levels connected with A (as illustrated by A′), but Dr. J. J. Hopfield is now investigating this matter experimentally, and has just obtained a beautiful plate showing a large number of bands, apparently constituting several distinct groups. One of these lies in the region indicated by A − X in Fig. 1. It is known that the ionisation potential of the neutral N_2 molecule is close

·7 volts, and since D – A equals 55,200 (=6·8 t, it is evident that A – X must be less than ten

Prof. E. P. Lewis has directed my attention e great experimental difficulty in obtaining the th Positive Group, discovered by Fowler and t. There is evidently a very narrow range of imental conditions under which it appears. is in agreement with the above diagram, where s only two volts from ionisation.

e maximum available electronic energy of active gen is therefore given by B′ – X, and since A = 28,127 (=3·5 volts), while A – X corresponds ably to about 8 volts, B′ – X is equivalent to t 11·5 volts. Saha and Sur assume that active gen is merely a nitrogen molecule excited with volts energy. This assumption precludes the bility of emission of the α-group bands, and s no explanation of the distinction, in intensity ibution, between the α-group of the afterglow the ordinary First Positive Group.

of. E. P. Lewis, at the time of his original dis- ry, stated that a trace of oxygen was necessary he formation of the afterglow. After a prolonged ssion, in which various investigators participated, as mutually agreed that this statement was ct, except that *any* electro-negative substance uced an analogous effect (enhancement of the glow). Now a molecule can remain in a meta- le state only in the absence of any disturbing . Under the conditions obtaining in the region re the afterglow appears, the chief disturbing is that caused by the collision of other molecules f free electrons with the metastable N_2 molecules. tron collisions would be particularly effective in ing a reversion to the stable state. But Prof. is has shown the presence of some free electrons he afterglow (NATURE, 111, 599, 1923), and has gested that this trace of electro-negative substance eeded to "clean-up" the electrons in the side e, and thus to prolong the life of active nitrogen. terms of the present theory we would say that t active nitrogen molecules revert to the stable n in the main portion of the discharge. Some fortunate enough to diffuse into the side tube, re under suitable conditions they could exist finitely. With no electro-negative element sent there is sufficient concentration of free trons to cause the immediate reversion of the ve nitrogen, before it has had time to diffuse any reciable distance, and possibly directly to the le form X, with the emission of high-frequency ds. On the other hand, any excess amount of an tro-negative substance acts in a similar disastrous nner upon the metastable molecules.

Even with the small necessary amount of oxygen, re will be some collisions between oxygen molecules l active nitrogen molecules. We may assume t this results in the formation of a special form of tronic excited NO molecule which reverts to the esumably) stable form of NO with the emission the β-bands, discovered by Prof. Lewis in the after- w. Dr. Mulliken, to whom I am indebted for ny suggestions in this matter, has suggested that s type of electronic excited NO may be metastable. this is true, we have, in one sense, another form of ctive nitrogen." But, as stated, it seems prefer- le to reserve the term for the emitters of the α-group nds. We may assume, further, that more usual pes of union of oxygen and nitrogen may produce different form of electronic excited NO which erts to the stable form with the emission of the ands (Third Positive Group). The β- and γ-bands em, from certain mathematical relations, to have common final state, and if so must be due to the ne molecule. This question is discussed by Dr. Mulliken (*loc. cit.*), who independently found this common state.

In conclusion, then, I assume that if the emission of any group of afterglow bands is a primary phenomenon, the emitter must be a metastable molecule, which may be called "active." This certainly seems true as regards the α-group. But if the emission is a secondary phenomenon, occurring as a consequence of "second-type" collisions with a metastable molecule, the emitter need not be metastable. It does not seem possible, at this time, to state any very definite conclusions as to the mode of excitation of the β- and γ-groups.

The Shrinkage of Gelatin.

IN a letter in the issue of NATURE for October 18, Prof. D'Arcy Thompson makes the attractive suggestion that the curved surfaces generated when cylinders or simple polyhedra of gelatin gel are allowed to dry (described by me in *Koll.-Zeitschr.* 35, p. 67, 1924) bear a strong resemblance to the minimum surfaces over the corresponding boundaries. Such minimum surfaces are easily produced by stretching soap films over openings or wire frames of the desired outline.

The suggestion receives additional support from the conditions prevailing in drying bodies of elastic gel: the edges dry more rapidly than the faces, providing a framework which is almost rigid when drying has progressed sufficiently, and the faces dry more rapidly than the interior. A skin is accordingly formed under stresses not unlike those to which a soap film stretched over an opening and exposed to pressure on one side is subject. Nevertheless the resemblance is approximate only, as can easily be seen when the contours of the two types of surfaces on planes parallel to the boundary are examined.

The curved surfaces which form when cubes or regular tetrahedra of elastic gel are dried have the very peculiar property that *their contours on planes parallel to the original face are rectilinear polygons similar to the original boundary* over the greater portion of the surface. This property was found experimentally, by actually drawing the contours on the dried polyhedra. Fig. 1 shows the body

FIG. 1.

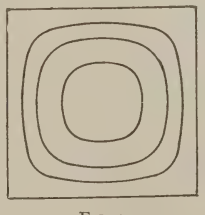

FIG. 2.

which results when a cube of 15 per cent. gel is dried at room temperature, with three contours drawn on it. It is a simple matter to express this condition analytically: if the profile curve, say, on the diagonal of the cube face is of the form $z = F(r)$, the equation of one quadrant of the surface in cylindrical co-ordinates must be of the form

$$z = F[r(\cos\theta + \sin\theta)],$$

where the r, θ plane is parallel to the original face, and $\theta = 0$ for one diagonal.

Since the equation of the profile is not known (it is very approximately a simple sine curve), the equation of the surface and that of the corresponding minimum surface over the square boundary cannot be compared directly. The surface can, of course, be easily produced by blowing up a soap film over a square opening, but the determination of contours on such a film calls for somewhat delicate experimental arrangements (cf. Griffith and Taylor, J. Inst. Mech. Eng., No. 1, 1918, p. 755). The error is probably not great if a very thin rubber membrane is blown up with low pressure, and I have carried out this experiment and drawn the contours, which are shown in Fig. 2. They are curvilinear and approximate to circles the more the apex of the surface is approached. While there is a certain resemblance between the surfaces produced by drying polyhedra and minimum surfaces over the same boundaries, the two are, therefore, certainly not identical.

A rational treatment of the problem does not appear hopeful, as two questions of very great difficulty are involved. It would be necessary to find the law according to which the water content varies from place to place, and then to deduce the conformation from the relation between water content and the elastic constants. Even the latter are known very incompletely; over a moderate range of concentration Young's modulus is approximately proportional to the square of the gelatin content (Leick, 1904), but this relation holds up to about 45 per cent. only, whereas air-dry specimens have a gelatin content of 80 to 85 per cent. EMIL HATSCHEK.

London, October 21.

The Causation of Cancer.

THE notice which appeared in the issue of NATURE of October 4 of my book, "Cancer: How it is Caused, How it can be Prevented," contains several misstatements which I must correct. The reviewer puts into my mouth the statement that "cancer is due to constipation and lack of vitamins" as a summary of my teaching, although I have stated in every chapter that cancer is due to chronic poisoning and to vitamin starvation, a totally different matter. The reviewer also states that "Almost the only authorities he quotes are surgeons" and "Their statements [are] mostly from the general press." From the bibliographical index at the end of the book every reader can see that the majority of my witnesses are physicians, physiologists and chemists, although there are a great many surgeons. Besides, my quotations are not "mostly from the general press" but from the leading scientific periodicals, as will be seen by reference to the section "Periodicals Quoted," contained in the bibliographical index.

Further, the reviewer says that I "put forward the pious belief . . . that cancer is a disease of civilisation," giving the impression to readers that I have drawn upon my imagination. In reality, the fact that cancer is a disease of civilisation is fully proved by the pronouncements of more than a hundred physicians practising among uncivilised nations, whom I have quoted and to whom I have referred. The reviewer's statement that I recommend "eating raw food and roots like the beasts in the field" for preventing cancer is another distortion. I have recommended a diet rich in vitamins and in roughage, a diet consisting largely of wholemeal bread and plenty of raw fruit and salads.

In conclusion, the reviewer states that my book "will do much more harm than good." I have received hundreds of letters from cancer sufferers both medical and non-medical, informing me that their case cancer was undoubtedly caused by chron poisoning and vitamin starvation, and I am receivi every day letters from readers, telling me that the health has been vastly benefited by the adoption the diet recommended in my book.

J. ELLIS BARKER.

Albion Lodge, Fortis Green,
East Finchley, N.2,
October 13.

I HAVE no desire to embark on a controversy wit Mr. Ellis Barker in a scientific journal like NATURE though I have behind me thirty years' study of ne growths. His hymn of hate above is no doubt a reli of the time when, as "Who's Who" informs us, h "devoted his literary career, ever since 1900, t warning England of the danger of a war wit Germany and to urging military, naval, and economi preparation." Mr. Ellis Barker may be an authorit on the foundations of Germany, British socialism tariff reform, and the Motherland and Empire, bu we must be pardoned if we cannot accept him as th authority on the cause and prevention of cancer Since the receipt of his onslaught, I have re-read hi book and my considered opinion is that it is ridiculous Mr. Ellis Barker must know perfectly well that th review of his book in NATURE is milk and water com pared with the vitamin-free strong potions that hav been administered to him on the subject of his boo by the *Lancet* (1924, ii. 70), the *British Medical Journa* (1924, ii. 324), *Science Progress* (1924, 328), *America Journal of Public Health* (1924, xiv. 787), and th Journal of the American Medical Association (1924 lxxxiii. 784). I do not, in fact, remember having read in the medical press such wholesale condemna tion of any book. THE REVIEWER.

The Choice of Wave-lengths for Achromatism in Telescopes.

MY attention has been directed to Prof. Townsend Smith's letter in NATURE of October 11, p. 536, in which he refers to my paper in the Transactions of the Optical Society. I entirely agree with the very useful curves he has drawn.

It would not be difficult to try the combination of the red lithium line and the F hydrogen line which he suggests, for no new measurements of refractive indices need be made.

In a paper, "The Existing Limits of Uniformity in Producing Optical Glass" (Roy. Soc. Proc. A., vol. 87, p. 190, 1912), a table of the refractive indices of twenty-seven different optical glasses is given, in contiguous columns in the order of their mean dispersions. Indices for both the lithium and the F line run throughout. Since the optical properties of the glasses in adjacent columns very closely resemble one another, interpolation for another glass, the mean dispersion of which lies between them, is easy.

Two later papers with similar tables have been published (Roy. Soc. Proc. A., vol. 91, p. 320, 1915, and vol. 100, p. 624, 1922), and they give a choice of fourteen additional glasses from which to interpolate.

At the end of his letter Prof. Smith refers to 546$\mu\mu$, the mercury line, as being not far from the correct minimum for the D and E curve. This is so, and some years ago I computed an object-glass where focal lengths for D and E were equalised with this mercury line for shortest wave-length, and it was afterwards constructed. Although definition proved

cent, the greens, blues and violets were distinctly
ed at the expense of the oranges and the reds,
ffect being slightly garish.
ter I computed an exactly similar combination
the exception that 561$\mu\mu$ now took the place of
, and the correction of all errors due to curvature
made for that line. This second object-glass
then constructed, and it was found that the
t referred to had been entirely removed.

"Ship-designs" on Prehistoric Egyptian Vases.

my friend Dr. Forbes has raised once more a
ion about the Egyptian ships, without quoting
ecisive examples, I would ask to supplement his
in Nature of October 4, p. 499.
the Gebel Arak ivory knife-handle is figured
sult of a naval fight between two types of ships
d opposite to each other, with the drowned men
between them (*Ancient Egypt*, 1917, p. 27).
Egyptian ships are of the same form as those on
Hierakonpolis wall painting (*Hierakonpolis*, lxxv.),
the two cabins and gangway between, and a top
er alike in both. The Hierakonpolis painting
shows a black ship with very high prow, like
of the enemy on the ivory, and like one with a
e sail on a vase in the British Museum. Each
ne Egyptian ships has the painter rope and
h at the prow, like that used to catch the wind
ne Swedish and Guinea coasting vessels. At
tern is the steersman holding the large steering
le. It does not seem possible to deny that these
ips.
w these vessels are exactly of the type of the
of the pottery paintings. The same outline,
s, space between them, and ensign at the hinder
, tying-up rope, and branch in the prow. If
are ships, then the sticks projecting below
are oars. The only argument for fixed forts is
the flamingoes indicate lagoons, but then most
itive waterways are bordered with lagoons.
cannot see how any idea of fixed habitations can
d with all these evidences of shipping, glad as
y be of any explanation by an eminent zoologist
t the living forms. Flinders Petrie.

Microseisms and Storm Forecasts.

E value of the seismograph as a detector of the
severe type of cyclonic storm in the Bay of
al was recognised some fifteen years ago by
C. W. Peake, then Meteorologist at Calcutta.
n I left the Observatory in 1922 it had become
ar routine for the Omori charts to be examined
microseisms during the writing of the Daily
ther Report, whenever pronounced symptoms of
rious storm existed in the south of the Bay.
-marked microseisms invariably confirmed other
ence in the case of the early stages of dangerous
ones, and were sometimes noticed when the
n centre was so much as 1000 miles south of
utta.
do not, however, recall any instance in which
oseisms were associated with ordinary rough
her or with an advance of the monsoon, but
bly a close scrutiny of the charts on the appro-
e dates would reveal the phenomenon. The
ral view in the observatory was that the seismo-
h ignored anything but a moving area of *excep-tionally* low pressure, and for this reason there is some doubt as to whether the obvious explanation that such microseisms are due to ordinary surface waves is the correct one; the large surface wave presumably always caused by the progression of the cyclone as a whole may, however, play a part in the production of the earth tremors. In any case, Dr. Banerji's suggestion (Nature, October 18, p. 576) that the vibrations he observed may be used in forecasting the date of arrival of the monsoon on the Malabar coast, is very interesting and should prove valuable.

Portsmouth.

Flight of Birds.

Some observations which I made on the flight of gulls two years ago on a trip to the Gambia were confirmed lately by observations in the Irish Sea and Atlantic. With the vessel (some 300 tons reg.) proceeding N.N.E. in a steady fresh E.N.E. wind, the gulls flew head to wind, keeping practically the same position in or over the stern of the vessel, apparently on motionless wings and with little or no updraft of air. While keeping head to wind they advanced *sideways* with the vessel going about 9 knots. I noticed the same attitude of gulls when the wind was quite ahead and the birds as usual, flying head to wind. In the latter case the birds seemed to have less difficulty in maintaining both their position and motionless attitude.

In practically identical weather, but with rather less wind force, I was surprised, on another day, to see gulls flap their wings continuously, a difference of behaviour which seems curious.

When up the Gambia River, on a calm day, I noticed a large heron flying along a few feet above the river surface. It gave a few flaps of its wings, then planed along some distance, then a fresh flap and again a plane, and so on for some distance but maintaining the same level. Recently, I constantly observed gannets fly in the same way.

David Wilson-Barker.

The Fluorescence and Channelled Absorption Spectra of Bismuth Vapour at High Temperatures.

Continuing our previous work on the absorption of light by bismuth vapour, we have found that the vapour exhibits, at a temperature of about 1300° C., an absorption spectrum composed of a very great number of bands presenting a fine structure, and extending from λ6500 to λ4500. We have photographed more than 400 bands in this region. These bands shade off towards the red end. At this high temperature, it is found that the vapour emits a fluorescent radiation orange-yellow in colour, and we have succeeded in photographing the fluorescence spectrum of the vapour at this temperature, containing about 24 bands ranging from λ6600 to λ5050. Hitherto bismuth has not been shown to possess either the fluorescence or channelled absorption spectrum in this region. Full details of the experiments, together with the photographs of the fluorescence and channelled absorption spectra of the vapour at this high temperature, will be published shortly.

Health and Physique through the Centuries.[1]

By Dr. F. C. SHRUBSALL.

IN his presidential address to the Section of Anthropology at the Winnipeg meeting of the British Association, Prof. J. L. Myres asked the question "What happens to Englishmen in city 'slums'?" or, in other words: How are the peoples of Britain adapting themselves to modern conditions? Are these conditions producing modifications in the racial constitution and qualities of the nation? The matter is one of importance to the older country, for more than three-quarters of the population now reside in urban districts, and to the newer, since in the course of time industries must concentrate in favourable localities and close aggregates of population necessarily arise.

The trend of events can be followed in outline from demographic data from about the fourteenth century, though the records are scanty until the nineteenth century. The main factors are urbanisation and industrialism, the combined effects of which can be seen best, though in an exaggerated form, in those individuals who follow certain trades, such as the textile industry, which associate dense aggregation with, even at the best, unhealthy conditions of occupation.

Indoor trades and factory life introduce very different physiological conditions from those under which the young peasant has his being. These factors tend to depress the vitality of the incomer from the country, while those born in the industrial township would be exposed to urban conditions throughout early as well as adult life, and have the further handicap in infancy of the lack of care inevitably associated with the factory employment of the mothers.

In addition, selection may in time sensibly modify the distribution of the various racial elements of the population. Psychological factors, too, come into play, for some types seem to prefer the freer life of the open spaces and leave a district as it becomes more densely settled; while others, who have no love or aptitude for solitude, migrate into the growing towns. The early settlers of the North American continent were drawn largely from areas occupied by Nordic peoples whose early history was that of hunting and fighting communities. As the eastern edge of the continent became settled, it was this type that was largely represented in the pioneers of the West.

The most alarming data in regard to the position in Britain come from the report of the Ministry of National Service on the findings of the recruiting boards during the last years of the War, but a reassuring comment was made by the Commissioner for Yorkshire, who pointed out that grading for military purposes must, in many essentials, differ from grading in respect to fitness for civilian life, which, after all, is the factor of most permanent importance to a nation. No previous data had given any idea of the extent of age changes in efficiency, though it was well known that the period of maximum efficiency in active games was the ages under thirty. It is therefore not surprising that the numbers fit for severe strain should fall off after that age or that relatively few over forty should be fit f effective military service. There is no reason to thi that this is in any way a new condition associate with urbanisation, or that a similar census in pa centuries would have yielded any better result Another and more serious criticism of this report as a accurate survey of the whole state of the populatio of Britain rests on the fact that it was only undertake after some years of war, when the physical pick of th nation had already voluntarily enlisted.

The more valuable data are contained in the recor of youths born in 1900. The proportions of Grade varied from 80 to 85 per cent. in rural areas, more tha 75 per cent. in mining areas, 72 per cent. in the suburl around London, down to 49 per cent. in the crowde industrial areas of Lancashire.

There is nothing in the statistics to suggest that th British people have degenerated more than othe nations. The German pre-War figures showed 72 p cent. fit or prospectively fit for service and 28 per cen less fit or unfit for service, with the same contra between the rural and urban, the agricultural and th textile areas, as is noted in Britain.

Actual data on stature are very sparse in the repor of the recruiting boards. A large number of the adu male population examined as conscripts in 1918 ha statures between 64 and 67 inches, but the averag figure obtained has little significance as an index the whole pre-War population, since a large proportio of the tall stock had already enlisted. The lowe statures were found among the casual labourers an the textile workers, who had been subject to ba conditions of environment.

The returns from the School Medical Service sho that stature is, on the whole, greater in England an Wales to the south of a line drawn from the Severn t the Wash, with an extension northward to includ Lincolnshire and the East Riding of Yorkshire; i addition, scattered areas containing many tall childre occur in Westmorland, on the coast of Cumberlan in the far north of Lancashire, in the hilly districts Staffordshire, and in Merioneth. This line of demarca tion clearly marks off the industrial from the rur districts, though it also largely coincides with areas former Saxon, Danish, and Norwegian occupation. Th children in factory towns and mining areas are i general definitely shorter than those in rural district The best physique is found in the great public school then in order come other secondary schools, the trad schools, and the ordinary elementary schools; thes correspond pretty well to the leisured and professiona the commercial, the artisan, and the factory an labouring classes respectively. The stature of th children from the better-class schools, many of whor present Nordic traits and all of whom have bee brought up in a favourable environment, is equal t any in the world. The general average for all type of schools is, however, below that of the children British descent in the Dominion or the Commonwealth The advantage of the latter supports the opinion tha the emigrant stocks from Britain contained a larg

[1] From the presidential address to Section H (Anthropology) of the British Association at Toronto delivered on August 7.

rtion of Nordic elements, and also suggests that ildren flourish under the new environment.

neolithic times, so far as can be gleaned from al remains, the average stature of adult males bout 63 inches with a few taller individuals inter- d, who were perhaps of the ruling caste; the is averaged about 66 inches, the Norwegians and s were a little taller. Throughout the medieval l, stature remained little affected so far as can lged from clothes, implements, and armour, which t suit the larger number of the present-day people would indeed be too small for the better built. e eighteenth century there were many recruits e stature was only about 63 inches.

cords of children of Lancashire operative and ring classes, taken in the second quarter of the eenth century, when compared with similar figures e present day, show little change until the last ears. Since the initiation of the School Medical ce, it has become evident that a gradual improve- is in progress. In London elementary schools has been a gain of a full half-inch in stature since while in the public schools average gains of an or more are recorded. The changes in weight are more general and significant.

mparisons which have been made between children have suffered from illnesses and those who have none of importance show the greater stature of tter class; many children fail to attain their full re on account of morbid factors which may act e growing bones directly, as in rickets, or indirectly gh malnutrition resulting from infectious ailments, rhs, or actual privation.

king a more general survey, the health of a people r varying conditions may be measured by the tion in the duration of life, which appears to have ased steadily from the earliest times. The great has been that more now live to middle age or nd. The expectation of life varies from class to much as does physique, being greater for the ssional classes than for the agriculturist, for the ulturist than for the miner, while the latter in is a better life than the tailor or the textile worker. so seems that there is a greater expectation in those s which, at any rate until recent times, were pied by a predominantly Nordic population.

eneral health has often to be estimated from the rds of mortality, though it must be remembered morbidity is much greater than mortality and that fter effects of injury or disease may long affect the sique of the sufferer. Lethal agencies are some- s local, sometimes widespread in their action, and at times exert a selective action on the population cted.

ar in early culture might occasionally wipe out a le population, but more often the skilful and strong ived; in modern war the selection favours those se physique does not permit of active military ice and is thus opposite in tendency. War acts e lethally through the social disorganisation, and consequent famine and disease, which follow in its n, than through any casualties in the field; from e direct experiences on its own soil, England has n singularly free since the Norman period. Thanks aps to the great demand for labour and to the separation allowances, as well as to the seat of action being abroad, the recent War has exerted no obvious harmful effects. The children have been well nourished and there was no great increase of defective children, such as had been anticipated by some, even in the areas most exposed to air raids. There was, it is true, an increase in the number of children who were trouble- some and educationally backward, but on examination it was clearly seen that these features were not due to innate characters but to truancy and lack of discipline during the absence of their fathers.

Famine took its toll in Western Europe in the medieval period, but England was the country in which the mass of the people soonest attained to fairly constant comfort. This was a great contrast to France, which repeatedly suffered from long years of famine. Harrison in his "Description of Britain" quotes a Spaniard in Queen Mary's day as saying "These English have their houses made of sticks and dirt, but they fare commonly as well as the king." In general any morbid influences on nutrition arose rather from a seasonal scarcity of certain essential articles of diet than from famine in the ordinary acceptance of the term.

Disease, throughout the historic period, must have been the most lethal of all the morbid agencies; there is nothing to suggest that there are important diseases to-day from which our ancestors were free. On the other hand, certain of the scourges of our ancestors have practically disappeared, especially some of the infectious diseases. Leprosy and plague long ago ceased their ravages, typhus and famine fever vanished, save for isolated cases in later Victorian times, enteric fever has lessened nearly to the vanishing point, and even infantile diarrhœa is becoming less year by year. Most, if not all, of these diseases may be communicated by animal agencies, either by direct inoculation from bites or by secondary contamination. The louse, the bug, and the flea, common until recent years, are succumbing to the newer tradition and meaning of cleanliness which has followed universal education, the medical inspection of scholars, and the action of public health authorities; the fly, an indirect agent, is being eliminated by improved sanitation and the gradual disappearance of horse transport in our cities. As the changes proceed more rapidly in the towns the approxi- mation of their health conditions to those in rural areas follows.

The mortality in early years was very high; thus in 1754 the deaths in London of children under two years of age were 45 per cent. of the deaths. Infant mortality has oscillated around 160 per 1000 until 1900, since when it has fallen to 60 per 1000 in 1923. A great part of the reduction has been in deaths due to infectious diseases and especially to diarrhœa; there has been little or no change in the rates from congenital defects or developmental disorders, which have remained relatively unchanged in all classes of the community, so that this lethal selection against the naturally unfit remains as rigid as ever.

Mortality in the early years of life is greater in the cities than in the small towns and in these than in the rural areas; it is greater in the north than in the south for all classes of the community, but it must be noted that with the great fall during the present century

the gap between urban and rural areas has been closing. This again suggests that education and a higher standard of personal hygiene are important factors, for the country is always more conservative in its actions and beliefs.

The mortality of the infants of agricultural labourers is less than that of those of any other class of manual workers, not only so far as diarrhœal diseases are concerned—here, perhaps, they have better chances of obtaining fresh milk—but also from measles, tuberculosis, and respiratory diseases generally. Some of the difference may be due to the rural child, on the average, being older than the townschild at the time he is attacked by infections; for, whereas infantile infections spread through towns about every second year, in the country districts there may be an interval of five years between periods of epidemic prevalence. The infant mortality among textile workers is especially due to diarrhœa, which may be ascribed in many instances to artificial feeding during the mother's absence at the mills. The children of this class also die notably from congenital malformation and prematurity, which might naturally have been attributed to the mothers working until a late stage of pregnancy, were it not that the mortality from these causes is even higher among the children of miners, whose womenfolk seldom work outside their own homes. On the whole the evidence goes to show that morbidity, and especially infant morbidity, is closely associated with the aggregation of population, but that in recent years improved standards of social or individual hygiene and comfort have done much to neutralise specific causes of ill-health. It may also be taken as proven that such ill-health is the greatest cause of stunting of physique. As in the past the countryside has been freer from these morbid influences; the countryman has been the physical superior of the townsman, comparing class with class.

There are three main ways in which the growth of towns and of the industrial system has prejudiced the health and thus the physique of the nation: adverse conditions of work, which had little influence prior to the eighteenth century, unhygienic housing, and bad feeding, which in varied ways have exerted their effects throughout a large part of human history. Some of these would be peculiar to the town, others would fall indifferently on town and country, and on all social classes save perhaps the very wealthiest, though even they could not entirely escape. The contrast is less vivid than would appear at first sight: the country child can get fresher food, it is true, but less of it perhaps, owing to the lower wages of his parents, though he often eats margarine, the butter being sold in the towns; he gets fresher air outside but not indoors, since the country cottage may be as dark, ill-ventilated, and overcrowded as any in a city court.

The greatest change in the conditions of work was the rise of the factory, involving long confinement in monotonously ventilated rooms, as opposed to work in the open at the door of the home. The early factory was an extension of the home. The introduction of water and steam driven machinery aggregated the populations into the northern towns which arose near the sources of the power, and put a premium on the employment of children who could then do work whi formerly required a man's strength. In recent ye the general hygiene of the worker, together with t removal of industrial risks, has made enormous stri the result being apparent in the falling death rate a the healthier children.

In early days the English dwelt scattered throu woods and marshes; in medieval times they began flock to the towns in which the sanitary conditio were bad; during the industrial revolution the aggreg tion of houses and the pollution of the air great increased and produced their well-known evils, thou the sanitation of the individual houses was, in sor respects, no worse than before.

Sedentary occupations in still warm atmospher have the effect of lowering the general metabolism a of reducing the desire for food, thus producing a simil effect to actual privation and affecting even the we paid worker. Acting through long periods during t growing time of life, such factors whenever they ar may stunt growth as well as predispose to illne Many dietaries which appear satisfactory on a me caloric basis prove failures owing to the lack of vit elements. The industrial worker is doubly han capped; he not only loses his appetite and tak scarcely enough to provide the necessary energy f his work, but also, too often, he takes even that the form of margarines and canned foods which not supply adequate vitamins. If, as is probabl physique suffered with the concentration of t population in the industrial areas, no small part ma have been played by the confinement in a relaxi atmosphere and the substitution of inert for live food The worker who emigrates to more rural surroundin reverses these conditions and, if young enough, recove part of his lost physique, and in any case his childre not being handicapped, fulfil their true potentialitie With feeding as with housing, though the industri age brought its own defects, yet the contemporaneo increase of civilisation provided the remedy for son of the previous evils, such as those arising from ir perfect methods of food preservation. The curing the best was very imperfect, and the diet of the poor classes would be the semi-putrid sides of bacon, mutto or beef. Indeed, it was enacted that such should l given to the outcast by the Scottish Parliament Scone in 1380. "Gif ony man brings to the mark corrupt swine or salmond to be sauld, they sall be take by the baillie and incontinent without any questio sall be sent to the lepper folke; and gif there be n lepper folke, they sall be destroyed alluterlie."

Modern medical inspection and treatment are fa counteracting the chief causes depressing the healt and physique of the children, and are also dealing wit contributory secondary factors, such as defective teet and other foci of chronic sepsis, verminous condition and unsuitable clothing. No one who compares photo graphs of present-day children with their predecesso of the 'seventies can doubt the change. It is significan that the town is now gaining over the country and tha London children are now second to none. The treat ment schemes did not come into force until just befor the War, and affected almost exclusively children wh did not reach military age in time to appear befor recruiting boards, so that the benefits of the syste

not be brought out in the report of the Ministry ional Service. In this direction the future seems

re remains the gap between the school and adult An experienced Scottish recruiting board reported ing off during adolescence both in the agricultural he industrial classes. With any extension of ilies for apprenticeship or trade instruction, with tunities for the further treatment of ailments, though these be of a voluntary character, much be gained. Moreover—since the use made of facilities would depend on the mentality and ter of the individual—the youth with the best and good will should gain the advantage and be red in his prospects of a successful marriage, gh which he could transmit these qualities to r generations.

ning to the genetic aspects of the subject, it is that the future of the nation depends on the uction of two somewhat opposed processes, repro- ve and lethal selection. Fecundity is a heritable and parents who themselves are members of families tend to produce many offspring who, in turn, are similarly prolific. Lethal selection, on ther hand, counteracts this tendency in that the nds of a large family reduce the chances of the its protecting themselves or their offspring, since vailable care has to be distributed over a larger er. It will be noted that the shorter the intervals een successive births, the higher is the rate of t and child mortality.

at reduction in fertility has been of long standing ikingly illustrated by Crum's study of the New and genealogies, in which he finds a progressive tion in the size of the family and an increase in roportion of childless marriages. The differential rate, chiefly due to infant mortality, to some t modifies the initial differences in fertility; the fertility of the agriculturist is largely opposed he low marriage rate, and the relative infertility he upper classes is exaggerated from the same e.

ere appears to be a general impression that the ber of defective individuals, particularly of those ring from mental defect, is greatly increasing. e is little evidence on this point of a comparable re, but it may be definitely said that in London uch increase has taken place during the last fifteen s. The stocks from which defective individuals e are certainly often prolific, but the infant tality is high. Contrary also to popular belief, tally defective individuals do not mate in nearly igh a proportion as the normal. There is some on for thinking that there is a great intermarriage veen defective stocks, and that the actual number uch stocks is in reality quite limited.

here remains one important factor bearing on sique—namely, emigration. Since the early part he seventeenth century the British Isles have sent ad large numbers of the most efficient of their ple, agriculturists and skilled workers of all kinds essed of just the qualities which the nation demands its own physical good. Where these have come n somewhat isolated areas the result has been a dy loss of the best, with the consequent replacement in the next generation by the offspring of an undue proportion of the next best. This—probably the most serious drain to which the nation has been, and still is, exposed—can only be regarded with equanimity on the ground that England's loss is the gain of the daughter nations. The emigrants have been largely of "Nordic" and "Prospector" stocks, seeking a wider scope for their energies, and the result will in the end seriously modify the racial composition of some parts of the British Isles, particularly Scotland.

Summarising the whole survey I would submit that a pessimistic view of the physical or mental condition of the people of England is unnecessary and unfounded. Stature and weight at least are not less than in earlier days. The War showed the possession of powers of resistance to physical adversity that have never been equalled. The general health of the nation is better and the expectation of life longer than ever before. There are no grounds for thinking the physical conditions of any class are worse than that of corresponding classes at previous epochs, even among those persons and classes on whom the adverse conditions of life associated with urbanisation and industrialism have pressed hardest and have been least opposed. The real increase of the unfit is much less than has been assumed from *a priori* arguments. Reproductive selection, which has a tendency to increase the apparently less valuable stocks, is opposed by a lethal selection which has not been abolished, while emigration, from the eugenic point of view, though a real disadvantage to England, has been a source of strength to the Empire of Associated Nations. The dysgenic tendencies of industrialism are being successfully opposed by the higher level of general culture and the awakening of a national conscience, but more especially by the more intelligent care for the children of the nation, in which the application of preventive medicine to education is playing no mean part. The Education Acts, if they have not revealed every child as a potential university scholar, have proved the best of public health measures; while all available evidence points to the intellectual average being equal to that of any other country. Civilisation may be making greater demands on its bearers, but their qualities are neither diminishing nor deteriorating and more and more are fitted to shoulder the burden.

Periodical surveys are necessary to check the changes in the population. Failing more extensive measures, these may be effected through the records of the medical inspection of school children, though in these anthropometric data are but scanty. The matter is of great importance, since it is only on the basis of careful physical and mental surveys that legislation directed towards social and racial hygiene could properly be introduced and rightly justified. The lack of such information has been a great handicap to the discussion of such measures in Britain, and has allowed a freer play to pessimistic views.

None the less, despite all forebodings, it may confidently be stated that the mother nation has remained true to herself and deserves now, as of yore, the encomiums of the "Polychronicon": "Engelond ful of pley, fremen well worthy to pley, fre men, fre tonges, hert fre, fre helth al the leden."

Why Wireless Electric Rays can bend round the Earth.[1]

By Sir JOSEPH LARMOR, F.R.S.

MYSTERY has remained attached to the transmission of free electric rays a long way round the protuberant curvature of the earth, which has recently developed into the greatest sudden practical evolution in signalling since the telephone. The difficulty was already emphasised by the late Lord Rayleigh, as soon as the first signs of transmission across the Atlantic had been detected by the Marconi operators. The effect has been sometimes supposed to be accounted for by a hypothesis that the rays are turned downward by an upper conducting layer in the atmosphere. But conduction, as usually understood, involves dissipation, and thus loss of energy of the rays by absorption; so that a train of radiation travelling along a layer sufficiently conducting to bend the rays could not go far. In fact, by a well-known dynamical principle, if the absorption is small of the first order, the resulting increase of velocity of the train is small of the second order and so of no account for bending rays in a varying field.

There seems, however, to be a sufficient and rather striking cause available for transmission of long waves horizontally round the earth at great altitudes, though the rays travelling at lower heights would be gradually quenched. For the synchronous oscillations of free ions of small mass go on undisturbed by collisions in very high regions of the atmosphere, and have time owing to the long period of the exciting waves to get up high speed and so become important under the influence of the field; much as the electrons in a triode valve have time during the electric oscillation affecting them, or rather in this case during their passage, to get deflected on to the grid. In an extremely tenuous atmosphere, this free ionic oscillation would be almost the sole conceivable deflecting agency. On the other hand, the absorption that would accompany ionic oscillations in ordinary conduction arises from the shortness of the free path, which leads to dissipation, through collisions with the surrounding molecules, of part of the extra energy acquired in the accelerated motion of the ions and thus abstracted from the electric field. When, as above, the period and amplitude of the oscillatory motions of the ions are much shorter than the time and length of their free path, so that the great majority of the oscillations take place without interference from collisions, this loss of energy will be very much reduced. A rough illustration of this principle is doubtless afforded, at the other extreme, by the remarkable penetration of the very short X-rays into light metals. It is not, of course, that conductance tends to become perfect, for then no waves could travel: the influence must be turned on to the dielectric modulus of the medium.

This cause must operate also for long waves travelling in the extreme limits of the atmosphere where the free path is great. The density aloft may be extremely minute: the long swing of the ions can bend the waves. The region in which the aurora borealis is displayed extends up to a height of fifty miles or more, and there the free atomic path for air would be about two centimetres. For radiation of wave-length of kilometre, with oscillating field of amplitude one v per metre and so transmitting $\frac{4}{3} . 10^{-7}$ watts p square cm., the amplitude of the oscillations of fr electrons would be about five centimetres, and f heavier ions it would be smaller inversely as th mass; while the time of oscillation for this length wave is only about a twentieth of the time of the fr path, at this altitude, for a molecule of the air, or quarter of the free time for a hydrogen ion. For electron moving with the speed of thermal equilibriu this time of oscillation would come to ten times t time of its free path at this height; this would entirely excessive and the electron would be an age of strong dissipation, were it not a reminder that t electron passes through the atom each time with b slight derangement of its free motion.

The long free path would in itself tend to augme the degree of ionisation. There must, of course, be many positive ions present as negative; but thou both influence the velocity of propagation of t waves in the same direction, the effect of the massi ones is negligible. It can readily be shown that t result is to reduce the effective dielectric modulus the medium, the value of which is close to unity, $N_0 e^2 \lambda^2 / 2\pi m$, where N_0 is the numerical density the ions of charge e and small inertia m. The amplitu of free oscillation of each ion would be $e\lambda^2/4\pi^2 mc^2$. in a field of amplitude F_0. The velocity of propagati v is increased relatively by the first of these amount which is for the same stratum proportional to t square of the wave length λ. The curvature of t horizontal rays in any stratum is equal to $d \log v/d$ the rate of relative increase of the velocity upward which is here $\frac{e^2\lambda^2}{2\pi m} \frac{dN_0}{dh}$. The stratum of transmissi to great distances is the one for which this is exact the same as the curvature of the earth, namely, $\frac{1}{2}\pi . 10^{-7}$ For electrons this gives dN_0/dh equal to 10^{-5}, f hydrogen ions 1700 times this; thus if this adaptati of curvature applies to a sheaf of rays extending ov the height of as much as a kilometre, N_0 need n mount to more than one electron per cubic cm. for th wave-length of one kilometre, whereas the number the atoms would still be as much as 10^{14} per cubic cr at the height of fifty miles, which gives a sufficient fr path for material ions. For hydrogen ions, N_0 woul have to be increased to $2 . 10^3$ per cubic cm., whi the amplitude of oscillation would be reduced 17 times so that the effective stratum need not be high; if free electrons also are present in number in thermal equilibrium, they would introduce dissipa tion of the rays passing at levels considerably high than this rough illustrative estimate of fifty miles, were it not that their motion, more potent on accour of their smaller mass, is so slightly deranged b passing through an atom as to compensate for th much greater number of such encounters.

These considerations remain valid in a general wa when the strata of equal ionisation are not exactl horizontal. If any cause, such as the influence sunlight on the ionisation, alters the height of th

[1] Abstract of a paper read on October 27 at the Cambridge Philosophical Society.

effective stratum too suddenly, the rays will be bent away upward or downward, and scattered, at the place of dislocation, and may not be able to get adjusted into the new stratum of transmission. If, however, the stratum is thick, the dislocation will be incomplete, extending over only part of it. The stratum may be expected to be of varying height, some function of the local solar time; but it is too high for any merely meteorological derangement. All rays emitted not nearly horizontally are lost: a good local earth would assist the antennas here. We can think of the constituent beam of rays connecting the transmitter with a receiver anywhere along the path: it travels most of the way, without loss except by spreading sideways, in the effective stratum, in which all such beams unite to form a nearly horizontal band of rays, the rough analogue of an optical caustic, in the almost vacuous region above. Each receiver collects from an area around it of the order of the square of the wave-length: it thus appears from numerical estimate that the amount of energy available need not be at all inadequate to account for the now familiar features of free electric transmission round the earth, even to the antipodes and beyond.

Obituary.

Dr. J. E. Campbell, F.R.S.

THE sudden death, at sixty-two years of age, of John Edward Campbell has come as a grievous shock to many. It removes from among us, in the height of his powers, a pure mathematician of strong individuality, and of conspicuous achievement in departments of research where few, in the British Isles at any rate, could bear him company. It deprives the small fraternity of mathematical lecturers in Oxford of a recognised leader, both revered and beloved. It means the loss to his College of a tutor no less devoted and successful than distinguished, who also served it in administration as acting head during the last years of its great Principal, Dr. Boyd. It leaves certain causes of philanthropic and religious work in Oxford sadly the worse off for working friends.

Campbell was the son, born at Lisburn, Co. Antrim, in 1862, of Dr. John Campbell. After going through the Belfast College of the Queen's University with distinction he came to Oxford, rather older than most undergraduates, as a scholar of Hertford. Later he became fellow and tutor of the same College, after gaining all the ordinary academical honours. He was also for a good many years lecturer of University College. He became a fellow of the Royal Society in 1905. In the years 1920–22 he was president of the London Mathematical Society; while the University of Belfast made him an honorary doctor of science.

Geometry was the strong point of Oxford mathematics in Campbell's young days, and it was natural for him to choose his line of research with a certain geometrical predilection, but he never became a devotee of the pure geometry of Chasles like others who surrounded him. Prettinesses did not much appeal to him: he wanted to plough broad acres. Looking afield for them, he began the study of the theories of continuous groups and of contact transformations which that master-geometer Sophus Lie had exploited, and with Sophus Lie he stayed long. Most of his earlier writings were contributions to Lie's theories, and presently he wrote a comprehensive book upon them, the first one by a British author, and far from a slavish reproduction of Lie's ideas. The differential geometry of surfaces has for long been another subject of his study and productiveness. More recently he has plunged into the time-space of Einstein in hopes of finding firm ground, as witness his presidential address to the London Mathematical Society.

There was a wonderful charm about Campbell's personality. Transparent rectitude, playful humour, the courage of his opinions, all shone from him to those who knew him. Affectation was as alien to his nature as idleness, and he could not be ungenial. In fact, he was the sort of Irishman whom it is a joy to run against. Some, hearing him for the first time, may have fancied that he had brought his Scotch name and his quaint accent unfamiliar to southern ears from somewhere to the east rather than the south-west of Campbeltown, and perhaps a comparatively remote Scottish ancestry may have had to do with the sturdiness of his principle and the forcefulness of his determination. Patient he was at his work, tolerant of stupidity, kindly in his joking, but there was a fire underneath which showed itself when what he thought wrong was in question. In the middle of 1914 he was a heated Ulster patriot. August came, and the lesser patriotism was submerged by a flood of the greater. A dearly loved son was an early sacrifice. During the War there was nothing else to him that mattered. He lived to serve those who fought for the right.

The War over, Campbell returned to his mathematics and to his tutorial work with young men. Of the latter, another generation or two have learned to be thankful for his precept and example. Of the former, a new book from his pen—one on differential geometry—will shortly speak.

WE much regret to record the death on October 4, at the age of seventy-seven, of Dr. Joseph Moeller, emeritus professor of pharmacognosy in the University of Vienna, and we are indebted to the *Chemiker Zeitung* for the following details of his life and work. Dr. Moeller studied in Vienna and was appointed an assistant in the pharmacological department in 1871. After the publication of his work, "Vergleichende Anatomie des Holzes," he lectured on natural products in the technical high-school at Vienna, and he was awarded the *venia legendi* for pharmacology of the University. In 1886 he was appointed professor of pharmacognosy at Innsbruck, and in 1893 he left that University for Graz. Later he returned to the Medical Faculty of Vienna, where an independent Institute of Pharmacognosy was built for him. Among other publications Dr. Moeller was the author of "Mikroskopie der Nahrungs- und Genussmittel," which has been translated into several languages; "Anatomie der Baumrinde"; and, with Ewald Geissler, of the "Real-Encyklopädie der gesamten Pharmacie."

Current Topics and Events.

IN the leading article of our issue of September 27 we dealt with the question of University Staffs and University Finance. In the course of the discussion we endeavoured to make the point that where the functions and responsibilities of the staff varied continuously from the lowest to the highest of its members, a reasonable case could be brought forward for a similar continuous variation in remuneration. To illustrate the point, the case of the University of Edinburgh was quoted, where this question has recently been raised in an acute form. We stated that the "average salary of the members of the non-professorial staff (248) was about 260*l*. and that for the professorial staff (52) about 1100*l*." Our authority for this statement was contained in a memorandum issued and signed by a staff committee of sixteen containing names of some eminence. Prof. Barger, of that University, writes querying the accuracy of these figures and suggesting that they are misleading, in that there must have been included "a large number of physicians and surgeons of the Royal Infirmary, professors in the College of the United Free Church, advocates, part-time demonstrators, etc."; that the full-time non-professorial staff is about 123 with an average salary of 433*l*. He does not tell us what would be the average salary of the professorial staff in these circumstances, nor does he quote his authority. We must leave the question to be decided at Edinburgh, but our main contention remains, of course, unaffected.

A CORRESPONDENT writes:—"Our Dutch colleagues have done well to keep green the memory of their distinguished countryman, Van 't Hoff, by openly celebrating the jubilee of the conception upon which the modern doctrine of stereoisomerism is based, published independently by Le Bel in France and Van 't Hoff in Amsterdam, in the latter part of 1874. Van 't Hoff, it may be remembered, was brought up on a strange diet of Burton's Anatomy of Melancholy, Byron, Burns, and Buckle, yet his contribution was so made and so simple that it almost forthwith gave solidity to chemists' speculations as to the character of optically active compounds in particular, and it has prevailed up to the present day. A vast amount of solid work is traceable to the influence it has had. At the public meeting, held on October 25, in the University of Amsterdam, the foreign visitors were first welcomed by a representative of the Netherlands Chemical Society; addresses were then delivered by Profs. Cohen and Walden. Prof. Cohen's speech was an eloquent appreciation of the two men, the section devoted to Le Bel being particularly happy in its allusions. Prof. Walden appears to have prepared a complete account of the development of stereochemistry up to the present day, but could only summarise his conclusions. A reception preceded the meeting, and tea followed it. Unfortunately Le Bel could not be present. The French Chemical Society was represented by M. Delépine, the English Chemical Society by Profs. Armstrong and Lowry, whilst Mr. Woolcock represented the Society of Chemical Industry and the Association of British Chemical Manufacturers. An American wandering in Europe had been captured to appear on behalf of the American Chemical Society. Prof. Walden was the delegate of the German Chemical Society and also appeared for the Russian Society; it may be mentioned that he is now professor in Rostock; he was formerly in Riga. In the evening a banquet was given at the Hotel de l'Europe. The celebration on the whole was immensely successful. A friendly party of men, all understanding one another, united to give pious effect to the feeling of gratitude which all who can appreciate the great gift our science has received from the two men in whose honour we were assembled. Such exchanges of courtesy are of great value. These meetings, however, ever serve to remind us only too forcibly of our linguistic deficiencies."

IN his presidential address to the Institution of Automobile Engineers, delivered on October 14, Dr. W. R. Ormandy reviewed the fundamental work done by Ricardo, and by Tizard and Pye, on the phenomena and principles governing the efficiency of internal-combustion engines, and then dealt mainly with problems awaiting solution. The present method of taxing motor vehicles, by cylinder capacity, has led to the use of engines having very high compression-ratios, in order to obtain a high power with a given cylinder bore; but many engines fail in efficiency owing to pre-ignition of the fuel. Hence ability to withstand high compression is a very important attribute of a motor-fuel. The work of Midgeley and Boyd in America has opened up the possibility of using low-compression fuels in high-compression engines by adding to them traces of compounds of selenium, tellurium, or lead, but such substances are difficult to handle. For engines with more than one cylinder, the problem of distribution from the carburettor to the cylinder needs investigation with the view of finding distributing systems that will enable all types of fuel to be used freely in motor engines. "Cracked" fuels are rich in unsaturated hydrocarbons, and further research is needed on the relation between chemical constitution and performance in the engine. Another desideratum is a fuel which can be exploded in very weak admixture, as a means of improving the efficiency of engines working at light loads; hydrogen and, to a much smaller degree, methyl alcohol, and ether, satisfy this condition, but are ruled out owing to inconvenience or cost. Further progress in the discovery and investigation of new alloys, particularly those containing aluminium and magnesium, will have far-reaching effects on the future of the automobile industry. For these and other researches more money is required. In Great Britain money is fairly easily obtained for new processes that have advanced to a small commercial scale, but it is very difficult to procure for a discovery that needs investigation in the laboratory; in this respect Great Britain is behind Germany, where such work was not

nterrupted even during the most stressful periods of the War.

IN his presidential address on "Bretonneau: His Life and Work," delivered at the Section of the History of Medicine of the Royal Society of Medicine on October 15, Dr. J. D. Rolleston said that Bretonneau (1778–1862), by his clinical perspicacity in conjunction with careful post-mortem examinations, did as much for the study of acute infections as Laennec did for chronic diseases. Bretonneau was a remarkable personality whose services to medicine can be summarised as follows:—(1) He established the specificity of diphtheria and typhoid fever; (2) by his doctrine of specificity he foreshadowed the germ theory of disease; (3) in opposition to the physiological school headed by Broussais, who had discarded the materia medica and reduced treatment to bleeding, leeching, and a starvation diet, Bretonneau made several contributions to therapeutics, including tracheotomy for laryngeal diphtheria, a new method of administration of quinine in malaria, the use of belladonna in constipation and enuresis, the resuscitation of purgatives in dysentery and of martial preparations in anæmia, and the introduction of cod-liver oil in the treatment of rickets; (4) his work, especially his researches on diphtheria, by which he showed that the Syriac ulcer, malignant angina and croup were the same disease, illustrated the practical value of the study of the history of medicine.

A SLIGHT earthquake was felt in Birmingham and the surrounding district on the afternoon of October 24. From the information at present received, the disturbed area is about 24 miles long, 16 or 17 miles wide, and contains about 300 square miles, the centre being a few miles to the west of Birmingham. The shock was registered at Mr. J. J. Shaw's observatory at West Bromwich at 4·49½ P.M., the maximum intensity being about four seconds, and the last tremors about four minutes later. This is the fourth undoubted earthquake that has occurred in the neighbourhood of Birmingham. About the first, on November 23, 1769, little is known. The second, on November 15, 1772, disturbed a small area about 8 miles long and 4 miles wide, including Birmingham, but lying principally to the east. Still farther to the east, and extending from Birmingham to Coventry, was the disturbed area of a slight shock on January 31, 1888. A much stronger shock on August 27, 1922, felt over an area of about 650 square miles, has been attributed to the bursting of a meteorite (NATURE, vol. 110, p. 393).

DR. P. CHALMERS MITCHELL delivered the third Benjamin Ward Richardson Memorial Lecture on "Hygiene in Animal Food: Evidence from Zoological Gardens," under the auspices of the Model Abattoir Society, on October 23. Dr. Chalmers Mitchell stated that examination of the intestines of mammals and birds shows that the more primitive types in most classes are adapted to an omnivorous diet, and that the purely carnivorous and the purely vegetarian habits are more specialised. Man, although the most highly specialised in brain, is more primitive in some other organs, including the intestines. Until human beings change their habits, a meat supply will be required. At the Zoological Gardens, meat has to be provided for carnivorous and omnivorous mammals and birds, and the animals chiefly used are horses and goats. These are killed in a modern, hygienic abattoir. The rifle is used, and although on an average three horses are required in two days, in the last twenty years in only two cases has a second shot been required. Dr. Chalmers Mitchell is of opinion that there is little or nothing to choose between the rifle and the humane killer, the poleaxe or the knife, skilfully used under proper conditions, as the instruments of actual death. In his opinion and experience, animals have no presentiment of death, and even the fresh blood and warm offal of their fellows convey no message of fear to their consciousness. But they are readily thrown into panic by being driven into unfamiliar places. Every abattoir should therefore have attached to it proper stables or byres, and the animals should be tended and finally led out by men familiar with the handling of living animals. Particulars of the work of the Model Abattoir Society can be obtained from the hon. secretary, Model Abattoir Society, at the Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.

THE jubilee celebrations of the London (Royal Free Hospital) School of Medicine for Women were held last week-end. On Friday, October 24, a dinner was held at the Guildhall, which had been specially lent for this purpose by the Corporation of the City of London. Mrs. Scharlieb presided, and the toast of "Women's Work" was given by Dean Inge, Dean of St. Paul's. The toast of "The School" was proposed by Prof. E. A. Gardner, Vice-Chancellor of the University of London, and replied to by Miss Aldrich-Blake, Dean of the School; Mrs. Fawcett, Lady Barrett, and Prof. Winifred Cullis also spoke. More than 3000 women, representing all professions and callings in which women are engaged, gathered in St. Paul's Cathedral on Saturday afternoon to give thanks for "the opportunities for training, work, and service opened to women in the past fifty years." Of special interest, in view of the Jubilee Endowment Fund which is being raised to endow three chairs in memory of the three women pioneers in medicine, was the presence of the three nieces of Sophia Jex-Blake, founder of the School; and of Dr. Louisa Garrett Anderson, daughter of Mrs. Garrett Anderson, who was Dean of the School for 20 years. On Saturday, October 25, a party was held at the School, when past and present students and friends of the School were entertained. In this connexion there were some interesting scientific exhibits. Mr. Gardner, lecturer in organic chemistry, gave demonstrations with liquid air. An exhibit of crystals and crystal formation included some beautiful specimens lent by the Gas Light and Coke Co., Messrs. Burroughs and Wellcome, and the British Drug Houses, Ltd., as well as specimens made in the School laboratories. The physiology exhibits included optical illusions, tests for colour-blindness, the Sanborn apparatus for investigating respiratory exchange, measurement of

blood pressure, and microscopic specimens of various normal tissues. The Endowment Fund, headed by a donation from the Queen, has now reached a total of more than 26,000*l.*, including a reversionary gift of 10,000*l.* from a woman doctor in Harley Street.

THE Ramsay Laboratory of Chemical Engineering at University College, London, will be opened by Prince Arthur of Connaught on Wednesday, November 12, at 5 P.M. After the opening ceremony, the new building will be open for inspection.

THE Thomas Vicary lecture of the Royal College of Surgeons of England for the present year will be given at the College by Sir Arthur Keith on Wednesday, November 12, at 5 o'clock. The subject will be "Sir Richard Owen as Conservator."

APPLICATIONS are invited by the Zoological Society of London for their newly instituted Aquarium Research Fellowship, particulars of which were given in NATURE of August 30, p. 324. Applications for the fellowship must reach the Secretary of the Society, Regent's Park, N.W.8, by November 18 at latest.

APPLICATIONS are invited from members of the Royal College of Veterinary Surgeons with, if possible, experience in research work, for an assistantship in the Animal Disease Research Division of the Ministry of Agriculture of the Government of Northern Ireland. The latest date for the receipt of applications by the Secretary of the Ministry, Belfast, is November 8.

PROF. C. F. MARVIN, professor of meteorology since 1891 and chief of the United States Weather Bureau, has been appointed acting-secretary of agriculture for the United States, the secretaryship having fallen vacant through the death on October 25 of Mr. Henry Wallace, of Iowa.

THE Royal Airship Works, Cardington, require a skilled calculator, of either sex, with a university degree in science or engineering, who has taken higher mathematics in the degree examination. Experience in stressing of complicated braced structures is essential, preferably in connexion with the design of aircraft. Candidates with a knowledge of aerodynamics will be given preference. Applications should be sent to the Secretary, Royal Airship Works, Cardington, Beds.

THE Report on the Hunterian Collections of the University of Glasgow for the year 1922–23 is noteworthy for the large number of type-specimens included among the fossils presented to the geological department. These comprise plants from the Mepale Oil Shale of South Burma; Daunichthys, a new genus of fishes, with other fossils from the Dawna Hills, South Burma; corals, stromatoporoids, and brachiopods from Yunnan. Prof. J. W. Gregory also records the donation of a fine series of lead ores, calcite crystals, and other minerals from Wanlockhead and Leadhills mines by Mr. G. B. Findlay.

THE most recent annual Report of the Castle Museum, Norwich, records the gift by Mr. Gerard H. Gurney of the collection of British birds formed by his father, the late John Henry Gurney. The collection comprises 1500 bird skins and 49 glazed cases of mounted birds, and is of particular value for its examples of different stages of plumage. The report also tells of successful co-operation with the Norwich Education Committee. That body has appointed a museum demonstrator, who gives four demonstrations daily to a class of 25 senior boys or girls in their fourteenth year. The scheme allows of 500 scholars attending a full course of twelve consecutive demonstrations in natural science. A good feature is that the children have the opportunity of handling duplicate specimens.

WE have received the tenth annual Report for 1923 of the International Health Board, Rockefeller Foundation, reviewing the activities of the Board in all parts of the world. Its work includes propaganda, money grants in aid of public health education and for travelling and research fellowships, and campaigns against hookworm, malaria, yellow fever, and other diseases. The total expenditure of the Board for 1923 amounted to 2,452,728 dollars. The Report is characterised not only by the lucid and interesting text, but also by the number of excellent illustrations, charts, and maps. Short papers on the spleen index in malaria, the use of fish for malaria control, and the eradication and diagnosis of hookworm disease are included in an appendix.

WE learn from the *Lancet* that after the delivery on St. Luke's Day, October 18, of the Harveian Oration before the Royal College of Physicians of London, the president, Sir Humphry Rolleston, presented the Weber-Parkes Prize and Medal to Prof. A. Calmette, formerly of Lille, now sub-director of the Pasteur Institute, for his researches on tuberculosis. The president referred to him as the foremost authority on this subject, at the same time alluding to his researches into other aspects of bacteriology. He then presented the Moxon Gold Medal to Sir Leonard Rogers for his distinguished researches in clinical medicine. In doing so, he remarked that there were few tropical diseases in regard to which Sir Leonard Rogers had not laid the medical profession under debt by his investigations. He mentioned especially dysentery, kala-azar, cholera, and leprosy, and wished him success in his present researches into the treatment of tuberculosis.

THE New York correspondent of the *Times* states that the late Mr. Henry R. Towne, a manufacturer and engineer, has bequeathed the bulk of his estate, amounting to several million dollars, to establish museums in New York which shall be a "permanent exposition of American achievement in the peaceful arts." In case the trustees deem it inexpedient to establish such museums, the fund is to be divided equally between the Metropolitan Museum of Art and the American Museum of Natural History. A sum of 50,000 dollars (10,000*l.*) has been left for an educational campaign to bring before the American

ublic the essential facts in regard to the great industrial museums of Europe.

PLASTER casts of the Deinosaur eggs found by the Mongolian Expedition of the American Museum of Natural History (see H. F. Osborn, NATURE, October 4, p. 504) have been presented to the Trustees of the British Museum and are now on view, with elucidatory labels, in a special table-case at the entrance to the Geological Department. Beside them have been placed for comparison certain fossil eggs of reptiles, some of which have been in the Department since 1864. In this table-case it is proposed to show the more interesting recent acquisitions, changing them from time to time. There are also exhibited in it some remarkable fossil frogs and a salamander, in bituminous shale, of Oligocene (?) age, from mines at Libros, in the province of Teruel, Spain, the gift of Dom Longinos Navás, S.J., who recently described a new fauna from that locality, including also birds, beetles, spiders, and molluscs.

MESSRS. Wheldon and Wesley, Ltd., 2 Arthur Street, W.C.2, have just circulated another of their special scientific catalogues, namely, New Series, No. 14, which is devoted to "Zoology, Part 1—Vertebrata." Upwards of 1500 works are classified under the headings: Bibliography, Biography and History, General Systems and Iconography, Evolution, Heredity, Biology, Anthropology and Ethnology, Mammalia, Aves, Reptilia and Batrachia, Pisces, Domestic Animals and Poultry, Game Animals and Sport, Palæozoology, Miscellanea.

THE new list of announcements of Messrs. Longmans and Co. contains the titles of many books of scientific interest, among which are vol. 5 of Dr. J. W. Mellor's "A Comprehensive Treatise on Inorganic and Theoretical Chemistry"; "Glucoproteins," Prof. P. A. Levene, and "The Action and Uses of Digitalis and its Allies in Medicine," Prof. A. R. Cushny ("Monographs on Biochemistry"); and "Elements of Mechanism," Profs. F. S. Carey and J. Proudman.

MESSRS. C. Baker, of 244 High Holborn, London, W.C.1, have sent us a copy of their classified list (No. 82) of second-hand scientific apparatus. This differs slightly from the well-known quarterly lists previously issued by the firm in that the section dealing with photographic apparatus has been omitted. This is now issued separately. The catalogue still contains plenty of material, however, which is well worthy of consideration by scientific workers. Section I., dealing with microscopes and accessories, is particularly full, while there are also long lists of surveying instruments, telescopes, spectroscopes, and other physical apparatus. Surveying instruments are let out on hire for various periods by the firm.

Our Astronomical Column.

PLANET OR COMET?—A very interesting object, which was evidently stellar in aspect, but the motion of which is suggestive of a comet, was discovered by Dr. Baade at Bergedorf on October 23. The following positions have been telegraphed from the I.A.U. Bureau at Copenhagen.

	G.M.T.	R.A.	N. Decl.	Mag.
Oct. 23	$7^h\ 25{\cdot}5^m$	$21^h\ 5^m\ 16^s$	$15°\ 28'\ 0''$	10·5
25	$8\ 59{\cdot}0$	$21\ 15\ 31{\cdot}0$	$14\ 7\ 9$	9·5

Deduced daily motion, $+4^m\ 57{\cdot}8^s$, S. $39'{\cdot}15$.

If the object is a planet, it would seem to belong to the Eros type, with a perihelion far inside the orbit of Mars, so that it is of importance to obtain observations. Photography offers the readiest means of identifying it by its trail. The increase of a magnitude in brightness in two days should not be stressed, as it is difficult to estimate the magnitude of a trail.

On November 1 the estimated position is R.A. $21^h\ 50^m$, N. Decl. $9\frac{1}{2}°$, some 3° east of ϵ Pegasi. The object souths about 7 P.M., and is thus in a favourable position for observation.

TELESCOPES IN THE SOUTHERN HEMISPHERE.—An extract received from the *New Zealand Evening Post* contains an account of the inauguration of a 9-inch telescope at Kelburn, Wellington, under the auspices of the Wellington City Council. It is at present housed in a temporary wooden shed, in order to allow work on Mars to be undertaken, but a more suitable building is promised in the near future. The object glass is a photo-visual one, and it may be presumed that the mounting is equatorial, though details are not to hand. This interest of a City Council in pure science deserves grateful recognition.

From the *Observatory* for October we learn that Yale Observatory is accepting the invitation of Dr. Innes to set up a 26-inch photographic telescope in the grounds of the Union Observatory, Johannesburg, so as to continue the parallax studies of the American observatory in the Southern Hemisphere.

Dr. Innes has also organised a scheme of interchange of observers between Leyden and Johannesburg, under which Dr. Hertzsprung is at present at Johannesburg on a 15 months' visit; he will be followed by Mr. Van den Bos.

Dr. Innes makes a suggestion that every observatory should send annually to the International Astronomical Union a report on its work. Such reports would make it easier to decide on a programme of work without needless overlapping, and would help to keep observatories in touch with each other.

FINSLER'S AND ENCKE'S COMETS.—Finsler's Comet was followed at Heidelberg until October 6, but was then lost from its proximity to the sun. Dr. Kobold gives the following orbit in *Astr. Nachr.* 5326, using observations on September 20, 26, 30.

$$\left.\begin{array}{rl} T = & 1924\ \text{Sept.}\ 4{\cdot}3370\ \text{G.M.T.} \\ \omega = & 66°\ 31'{\cdot}18 \\ \Omega = & 80\ \ 2{\cdot}54 \\ i = & 120\ \ 9{\cdot}36 \end{array}\right\} 1924{\cdot}0$$

$$\log q = 9{\cdot}60855.$$

Encke's Comet was followed until October 22, being then of at least the fifth magnitude and visible in considerable twilight. The observations indicate October 31·437 G.M.T. for the time of perihelion passage.

Research Items.

A SKULL OF PAPUAN TYPE FROM COLOMBIA.—In *L'Anthropologie*, T. xxxiv., No. 5, Dr. R. Verneau directs attention to a close resemblance between the skull of a Tunebo Indian and Papuan skulls, particularly skulls from the island of Mallicolo (New Hebrides). Not only is the general morphological resemblance remarkable, but the absolute measurements are extremely close. The cranial index in each case is 69, and both are hypsicephalic. The maximum transverse diameters vary by three millimetres only, the vertical diameters by one millimetre, and the maximum antero-posterior diameters are identical. In both cases the frontal region is narrow. The chief difference is that the Tunebo skull has a higher cranial capacity, 1775 c.c. as against 1550 c.c. in the Mallicolo crania, probably an individual variation. Where in other respects it varies from the Mallicolo characters, it approaches those of other Papuan crania. Notwithstanding the danger which attaches to conclusions drawn from a single specimen, it appears reasonable to conclude that the Tunebo skull belongs to the Papuan type. Ten Kate and Rivet have demonstrated that traces of the early type of S. American man represented by the Lagoa Santa skulls are to be found from Southern California to Patagonia, while de Quatrefages and, later, Rivet pointed out the close resemblance of this type to the hypsistenocephalic type of Melanesia and Australia. The importance of the Tunebo skull is that it is the first of the type to be found in the Eastern Andes and supplies a link hitherto missing between examples of the type on the Atlantic and Pacific sides of the continent.

SURVEYS IN BHUTAN AND SOUTHERN TIBET.—In the *Geographical Journal* for October, Maj. F. M. Bailey describes a journey which he took for political reasons into Bhutan in 1921 and a subsequent journey through hitherto unexplored parts of that country and Tibet. His route was from Chumbi (Yatung) across the foothills of the Himalayas by Paro to Bumtang, where unexplored ground began. From Bumtang he passed northward into Tibet by the Mönlakarchung Pass to the lake known as Yamdrok Tso and thence westward by Talung to Gyantse. Capt. H. R. C. Meade with a survey party accompanied Maj. Bailey, and a map of their surveys is published with the paper. An area of 9493 square miles, including 6589 original survey and 2904 revision, was mapped on a quarter-inch scale, the work being based generally on triangulation carried out during the journey. Of this area, more than half consists of accurate plane tabling and photo-survey, and the rest of reconnaissance work. The whole of the Mo Chu basin in North Bhutan is still unsurveyed, though several prominent snow peaks were fixed, and the map between Bumtang, where touch was lost with the Assam triangulation, and Lhunbushö (on the Yamdrok Tso) is more or less in the air, and adjusted by astronomical work. The work in the *Geographical Journal* is on a scale of 1 to 750,000.

GONAD AND SOMA IN THE FOWL.—Pézard, Sand, and Caridroit (*C.R. Soc. Biol.* v. 89, 1923) describe on p. 1271 a case of feminisation of an adult Brown Leghorn cock which was castrated at the age of 3 months, and a year later received two implants of ovaries from hens of the same breed. The head furnishings and plumage are now henny. On p. 1103 the authors describe how in plucked ovariotomised hens, as the ovary regenerates, the growing feathers of the lumbar region mirror exactly the various phases of the process. In vol. 90, p. 623, they discuss the results of ovaria implantation into a castrated Brown Leghorn × Silv Dorking F_1 male, and of implantation of ovaria tissue without castration. In both instances there a swing to the plumage of the female and the appea ance of new pigmentation which differs according whether Leghorn or Dorking ovary was implante They suggest that there is a racial specificity of ovaria secretion apparently ignoring sex-linked inheritanc On p. 676 they discuss the phenomenon of pœcilandry the existence of two sorts of males in one and the sam breed. Cocky-feathered Sebright Bantam cocks ar to be found in France. From experiments in whic the testes from henny-feathered Sebright cocks wer implanted in a cock of a cocky-feathered strain, the conclude that the testes of the henny-feathered coc exercise the same effect as an ovarian implant. O p. 737 they describe briefly certain experiments o gonadectomy and implantation, and conclude tha castration results in a neuter form, which they designat " the species type," since they consider it to represen the common heritage of both sexes of the same breed the base upon which the end-result is built.

THE FOOD OF THE WILLOW-GROUSE IN NORWAY.—To *Bergens Museums Aarbok* for 1922–23, Dr. Jens Holmbœ contributes a detailed study of the food o *Lagopus lagopus* in the various parts of Norway i every month of the year, based on material collecte during 1921–23. So long ago as 1753, Pontoppidan remarked on the difference between the summer and winter diet, the latter consisting mainly of birch-twigs. It has also been recognised that the young eat insects, but these are soon given up and the birds live mainly on seeds, berries, and leaves. Dr. Holmbœ's researches show that there is also a considerable difference of food in the different regions, especially as between the coast and the inland districts, and this is chiefly manifest in winter. The reason clearly is that the snow renders the upland vegetation more or less inaccessible, so that the birds are driven to eat the twigs and buds of birch and other trees, or else to migrate to more favourable districts, whereas along the coast the snow does not lie so long and is swept away from the moors. Birch-twigs can be regarded as at best a substitute food, whereby the grouse can stay the pangs of hunger and live through the winter, but it would scarcely be satisfying in the long run. The Norwegian willow-grouse has until now been free from the parasite *Trichostrongylus pergracilis*, which is so dangerous to British grouse. This may be because the Norwegian birds do not eat much ling (*Calluna vulgaris*), which, as Leiper has shown, harbours this parasite. It now appears, however, that in the coast districts of Norway, Calluna does often serve as food for the grouse, so that increased effort should be made to prevent the introduction of British birds.

A SPECIES OF MONILIA ASSOCIATED WITH SEVERE ANÆMIA.—European residents in the tropics frequently suffer from a chronic or intermittent intestinal disturbance, in which amœbæ or dysentery bacilli are not found, to which the sufferers give the name " sprue." If this is a true infectious disease, an active agent is still to be sought, and therefore considerable significance attached to the work of Ashford in Porto Rico, in which it was suggested that the micro-organism *Monilia psilosis* was responsible for the symptoms. Lawrence Weld Smith, of the Department of Pathology and Bacteriology, University of the Philippines, now publishes in the *Philippine Journal of Science* (April 1924, vol. 24)

otes upon eight cases of severe anæmia associated ith the sprue syndrome in which *Monilia psilosis* shford has been isolated.

A BIOCHEMICAL BASIS TO DISEASE RESISTANCE.—n Œnothera, resistance to mildew disease is in-erited as a unit factor. Marañon has therefore used his species mainly in an investigation, described in he *Philippine Journal of Science* for April 1924 vol. 24, pp. 369-441), in which a preliminary com-arison is made of the biochemical constitution of isease resistant and susceptible strains. The con-lusion is reached that the resistant strains are haracterised by higher tannin content and more ater-soluble acid, whilst immune forms are com-aratively high in total nitrogen and total ash, the itrogen increase being mainly in amino-acids and itrogenous compounds of non-basic character, the sh increase in calcium and sulphur. Examination f disease resistant and susceptible strains of *Syringa ulgaris*, *Desmodium canadensis*, and *Solidago cana-ensis* is said to give concordant results.

AN EXPLOSIVE FRUIT.—The beautiful purple lowers of the South European species of toothwort, *athræa clandestina*, must have been noticed by nany visitors to the London parks; parasitic on lm or other trees and flowering freely in May, it is o be seen in Regent's Park, in the Bedford College rounds, at Kew, and at the Royal Botanic Society's arden. In the Quarterly Summary of the last body for October 1924) the Curator, Mr. J. L. North, has n interesting note upon the seed dispersal of the lant, which fruited freely in the Royal Botanic ociety's garden this summer. He was surprised to otice the force with which the seeds were scattered y the explosion of the capsule when squeezed etween finger and thumb. Although the capsule s born at ground level, the seeds are shot out so iolently that when, with the assistance of Prof. ates, their flight was followed and distances measured, ome of the seeds were found to have travelled 27 feet. his may throw some light upon the dispersal of the lant in the garden; originally planted upon the oot of a beech tree, it has now spread to the roots f other plants to a distance of 40 yards on either ide.

A NEW VIEW OF SOIL FERTILITY.—Prof. W. F. ericke of the University of California certainly eems to have developed a refreshingly novel point f view in relation to the problem of soil fertility, o judge from a preliminary note published in *Science* or April 4, which has just been brought to our notice. ointing out that the rapid growth of a crop often roduces a temporary depletion of some essential oil constituent, he investigated by the water culture nethod the effect upon the growth of a plant of a eriod in which the salt supply provided lacked one ssential element. The striking result was obtained hat after plants had grown for one month in complete utrient solution, a great enhancement of growth, ncrease in weight, and advance in date of maturity esulted from the transfer to solutions *devoid of otassium*. In the light of these experiments Prof. ericke attempts a reinterpretation of the results btained by Stewart (Journ. Agr. Res. 12, 311-368, 1918), in which it was shown the barley crop very apidly depleted the soil of nitrogen in the cases here large crops were obtained. From other water ulture experiments Gericke had reached the con-lusion that the presence of the nitrate ion materially affected the availability of the potassium ion to the plant, and he therefore inclines to associate these large yields in soils early depleted of nitrate with these new experiments in which lack of available potassium after the first few weeks of growth favours increased growth and yield. Needless to say, potassium, and indeed the full supply of nutrients, proves to be essential during the first few weeks of the plant's growth. Prof. Gericke reports similar improved development and yield in plants transferred, after four weeks in full mineral solution, to media devoid of phosphorus (*Science*, September 26).

THE PATHS OF CYCLONES.—The *Monthly Weather Review* for June contains an article by J. W. Sandström on "Investigations relative to the Polar Front," translated from *Meteorologische Zeitschrift* for February by Mr. W. W. Reed. It deals chiefly with "cyclonic families," and an attempt to apply the theory to practical weather service work. The theory asserts that after the passage of a cyclone, each succeeding depression has its path somewhat to the south of that of the preceding one until the cyclones move tangentially to the tropical belt of high pressure. The first members of the family appear in high latitudes. The theory is a consequence of the polar front conception put forward by Prof. J. Bjerknes. When the path runs in the vicinity of the tropical "high," a new cyclone family, it is said, appears in the north and behaves in the same way as the disturbances of the earlier family. The author, on the basis of this law, sought to draw in advance the paths of coming storms; he soon found that the storms followed quite different paths. An investigation was made on the basis of Hoffmeyer's charts. The first test failed to show that the succeeding cyclone lies more often to the south than to the north. The tracks of disturbances from Hoffmeyer's charts showed that the paths often intersect the paths of earlier disturbances in all kinds of ways. The author is of opinion "(1) that cyclone families in the Bjerknes sense do not exist, (2) that the behaviour of cyclones is not regulated by a polar front, and (3) that the discontinuity, which is called the polar front, appears, in general, only with the cyclones and is a result of their activity."

HISTORY OF OPTICAL GLASS.—In any historical appraisement of the makers of optical glass one name alone stands proud of all others—that of Pierre Louis Guinand. Endowed neither with riches nor education of a conventional kind, he converted a haphazard process of selection, which failed to satisfy the cravings of opticians, into a definite industrial art, the essentials of which constitute the universal practice of the present day. At the request of the German optician Utzschneider, Guinand in 1805 left his home in Switzerland to establish at Benediktbeuren an optical glass works, upon the success of which the fame of Utzschneider's firm and its productions quickly extended. According to the investigations of Dr. M. v. Rohr, published in the issue of *Die Naturwissenschaften*, September 26, it would appear that Joseph Fraunhofer, a young artisan in the glass-grinding shop, who had already won the good opinion of his employer, was transferred to the glass works in order that he might master the methods of Guinand. Two years thereafter he was placed in complete control—Guinand, the old experienced and renowned man of sixty-three, was made subordinate to the ambitious youth of twenty-five. Guinand returned to his old home in Le Brenets, and after the termination of his agreement with Utzschneider recommenced the labour of his life. His process was established by the Guinands and their associate, Bontemps, in France and Britain, where the manufacture has flourished and endured. In Germany the industry ultimately declined and entirely disappeared. Thus the ascendancy passed

from Germany until, in 1884, works were established by Abbe and Schott in Jena, where the process of Guinand is once more practised.

THE PHOTOELECTRIC EFFECT WITH MINUTE MERCURY SPHERES.—Dr. E. Wasser, in the *Zeitschrift für Physik*, September 12, describes an investigation of the photoelectric effect, using submicroscopic mercury spheres produced by evaporation and subsequent condensation in dry nitrogen and carbon dioxide. The particles were observed in an electric field with an Ehrenhaft condenser, the field being so adjusted that the observed particle remained suspended in the gas. Light of wave length $\lambda = 275\mu$ was employed to produce the photoelectric effect, and it was found that, up to about $1{\cdot}2 \times 10^{-5}$ cm. radius, the spheres were negatively charged, or there was an inverse photoelectric effect. From this radius up to $1{\cdot}9 \times 10^{-5}$ cm. some particles are charged positively and some negatively, while above $1{\cdot}9 \times 10^{-5}$ cm. radius all are charged positively. The magnitudes of the charges which the spheres acquire seem to depend on the radius; with small spheres charges of $0{\cdot}6 \times 10^{-10}$ electrostatic units, or about one-eighth of an elementary quantum, are much more frequent than charges equal to that of an electron; above 3×10^{-5} cm. radius, charge alterations down to about half the charge of an electron were observed. It is shown that these effects are not due to ionisation of the gases. The question whether the photo-effect has its origin in the adsorbed gas on the surface of the mercury, or in the interior of the metal, can only be answered when it is possible to investigate the same test particle with different gas pressures.

ELECTRIFICATION DUE TO BUBBLING GASES THROUGH FLUID METALS.—Messrs. A. Coehn and E. Duhme describe a series of experiments in which hydrogen, nitrogen, carbon dioxide, oxygen, and ammonia are bubbled through pure mercury and dilute amalgams (*Zeitschrift für Physik*, September 17). All these gases behave alike, and leave pure mercury negatively charged, while weak amalgams of "non-noble" metals (sodium, zinc, cadmium) are positively charged; "noble" metals (tin, copper, silver, gold) do not produce this reversal of sign. Lenard has concluded that, in the case of non-metallic fluids, the function of the bubbling gas is to break up the electrical double layer at the surface, and to carry off the charge which is least firmly held by the fluid. It appears that with pure mercury the electrons are held by the metal which remains behind more firmly than the positively charged mercury particles, which are carried off by the gas as a fine dust, giving it a positive charge. The effect with amalgams depends on the position of the metal employed in the electric tension series; a sodium atom, for example, gives up an electron to the mercury; and it must be assumed that the Na^+ ions bind Hg atoms, forming large $Na^+(Hg)_n$ complexes, which are less easily carried away by the gas bubbles than the corresponding negatively charged mercury particles. Thus the fine dust carried away by the gas must consist mainly of pure mercury; this is not necessarily the case with amalgams of the "noble" metals.

THE DOPPLER EFFECT AND CANAL RAYS.—When the light from canal rays is observed spectroscopically, the spectral lines are seen to be widened, owing to the different velocities of the radiating atoms. Dr. H. Krefft has photographed the β line of hydrogen under different conditions, and has measured photometrically the blackening throughout the band (*Annalen der Physik*, Aug.). He finds that the Doppler band is separated from the line which comes from atoms having small velocities; and that the intensity curve of the band has in general two maxima. The velocities corresponding to these are related, when the discharge voltage is abo 40,000, not as $\sqrt{2}$: 1, as is the case with the spark lin of oxygen and nitrogen; the ratio being larger th 2 : 1, and increasing with the voltage. Previo observers have found a limit for the Doppler effe when the voltage is raised sufficiently; but Kref who has used voltages from 1400 to 70,000, finds f the higher voltages that the effect increases regularl proportionally to the square root of the dischar voltage. The difference between the velocity distr bution, as determined by the Doppler effect, and t curve for that of the positive H atoms, as determine by electromagnetic analysis, is shown to be a necessar consequence of the facts that the carriers of t Balmer lines have no charge, and that the ratio of th numbers of positive and of neutral atoms depen on the velocity. With the spark lines of oxygen an nitrogen, where the "carriers" are the positive atom the two curves are nearly the same; and the tw maxima of blackening indicate a velocity ratio $\sqrt{2}$: 1, which is consistent with the assumption tha the lower velocity is produced by the movement of molecule with positive charge through the same voltag drop that produces the higher velocity in the positivel charged atom. The oxygen spark line $\lambda = 4591$ indicates extra high velocities, which must be due t the fall of doubly charged oxygen atoms through th discharge space.

MOBILE COMPONENTS OF CRYSTALS.—In Band 18 Heft, 1 of Eucken's *Fortschritte der Chemie, Physik un physikalische Chemie*, 1924, Dr. Hüttig contributes a essay with the somewhat curious title: "Übe Gitterbestandteile die im Kristallgitter vagabun dieren." It is pointed out that in some cases th particles in a crystal lattice, besides oscillating abou positions of equilibrium, may move through th lattice, and the rapidity with which this motion take place will influence the pressure-composition curve when a volatile constituent is withdrawn from system. A selection of such curves based on ver recent experiments is given, and these are divided int three groups. In the first group, *e.g.*, H_2O/LiCl, th solid residue consists of a mechanical mixture of definit compounds, and the phase rule applies in the simples form. When a single compound is present, th pressure curve drops vertically towards the composi tion axis. In the second group, *e.g.*, H_2O/WO_3 H_2O/Sb_2O_5, H_2O/SiO_2, the behaviour is intermediat between those of the first and third groups. In th third group, *e.g.*, O_2/UO_2, H_2/Li, and H_2O/Al_2O_3, th curve sinks continuously without any steps or change of direction. The laws of solution can be applied t the examples in the third group, and the whole curv covered by an equation $\log(p_0/p) = k/n$, where p, p_0 are the vapour pressures of the solution and of the pur volatile constituent, respectively, n the simple molecular weight of the volatile constituent, and k a constant. It is mentioned incidentally that X-ray experiments have shown that some so-called "colloidal hydrates" contain definite compounds. Thus, white tungstic acid does not show the spectrum of WO_3, and is presumably not a mere colloidal association of H_2O and WO_3.

ERRATUM.—We regret that in our reference to Early Christian legends in India (NATURE, October 4, p. 515) by a slip Malabar was substituted for Mylapore in the last sentence. Mr. Frederick Fawcett, who writes to point out the error, states that while the legend of St. Thomas is very much alive at Mylapore and on the west coast, it does not occur in the Malabar district of British India. He adds that the legends of St. Thomas on both the west and the east coast agree in a remarkable manner

Lake Level in Relation to Rainfall and Sunspots.

By Dr. F. DIXEY, Government Geologist, Nyasaland Protectorate.

VARIATIONS IN THE LEVEL OF LAKE NYASA.

THE present investigation was commenced towards the end of 1923 as a result of inquiries made as to recent variations in the level of Lake Nyasa; the information was required in connexion with proposed constructional work at or near the southern end of the lake. At the time the only information readily available was a record at the Marine Transport Department of the rise and fall of the lake level at the Bar, Fort Johnston, since 1916; the additional data now presented have been collected from many sources, and especial thanks are due to several past and present officers of the Marine Transport Department, as well as to residents and missionaries stationed on the lake.

The results of the investigation indicate that the lake level varies in close sympathy with the sunspot numbers. This relation is apparently due to the dependence of the lake level upon evaporation as well as upon rainfall, and to the fact that evaporation is very largely controlled by solar conditions. The researches of W. Köppen and others have established beyond doubt that there is a close connexion between sunspots and tropical temperature, the latter being 1·1° F. higher at sunspot minima than at sunspot maxima. It is reasonable to conclude that evaporation proceeds at a greater rate during the periods of higher temperature; hence at sunspot minima evaporation will be increased and the level of a lake suitably situated will consequently fall, whereas at sunspot maxima evaporation will be decreased and the level of the lake will rise. In the case of Lake Victoria, for example, this relationship has been found to be so intimate that it yields correlation coefficients of between 0·8 and 0·9; recent work has shown, however, that, for this lake at least, rainfall is also an important factor. The variations observed in the levels of Lakes Victoria and Albert and in that of Lake George in New South Wales, and shown to be closely associated with the seven-year periodicity of sunspot phenomena, have now been found to occur in the case of Lake Nyasa also.

Lake Nyasa, the third largest lake in Africa, is the southernmost of the Rift Valley lakes; it is 10,200 square miles in area and 360 miles in length, and it lies at an altitude of about 1645 feet. It is exceptionally deep, so that in places its floor extends down to about 600 feet below sea level. The area of the territory drained by the affluents of the lake is about three times that of the lake itself. The evidence of raised beaches shows that the level of the lake has fallen several hundred feet within late geological times. Until within the last few years the lake was drained by the Upper Shire river, which has now, however, become more or less completely silted up.

The curve depicting the variations in the level of Lake Nyasa is shown in the accompanying diagram (Fig. 1), together with those for Lakes Victoria and Albert and also those representing the rainfall of Uganda and the monthly sunspot numbers. It will be seen that Curve 3, showing the rainfall variation in Uganda according to figures available at the time, indicates that the level of Lake Victoria is undoubtedly dependent upon the rainfall, although the connexion is apparently small. Later work, however, has shown that the relation existing between the lake level and the rainfall of the whole of the surrounding area is much closer than would be supposed from this curve.

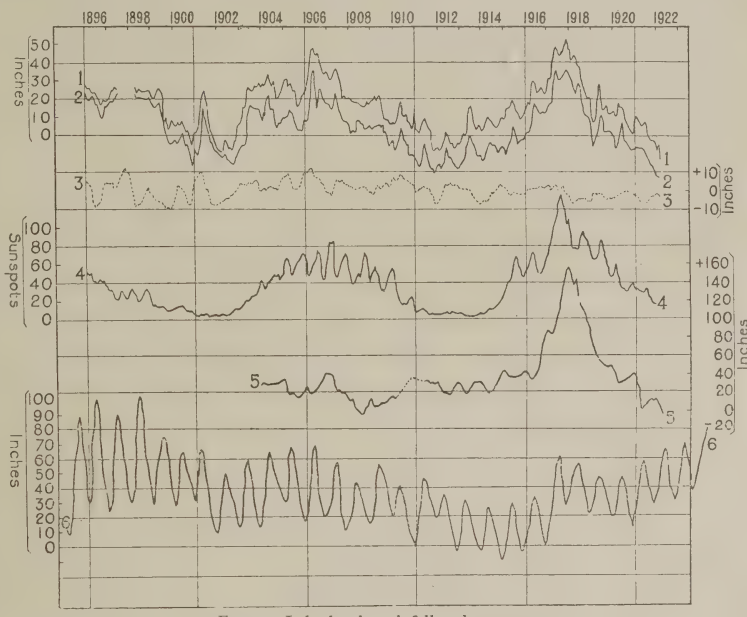

FIG. 1.—Lake levels, rainfall and sunspots.

Curve 1. Maxima, Lake Victoria.
Curve 2. Minima, Lake Victoria.
Curve 3. Rainfall in Uganda. Deviations from normal summed up in overlapping periods of six periods.
Curve 4. Monthly sunspot numbers.
Curve 5. Lake Albert.
Curve 6. Lake Nyasa: zero on the curve corresponds to 90 ft. mark on Lake George at the Bar, Fort Johnston.

Curves 1-5 are from Geophysical Memoir No. 20 (Meteorological Office, 1923). "Variations in the Levels of Central African Lakes Victoria and Albert," by C. E. P. Brooks.

Mr. P. Phillips, Director of the Meteorological Service, Cairo, has recently pointed out that there is actually a very high correlation (0·915) between the rainfall of the "Lake Plateau," which includes parts of Kenya Colony and Tanganyika Territory as well as Uganda, and the change in the level of the lake from year to year.

It is of interest to note that for the period under review the annual variations in the level of Lake Nyasa appear to have decreased, so that while they exceeded six feet in amount between 1895 and 1899, they have only attained about three feet since 1915; nevertheless, observations made at Cape Maclear for the few years succeeding 1875 show that at that time the variations were again only about three feet. These variations are all much greater than the corresponding changes in the levels of Lakes Victoria and Albert, and they are large also even as compared with the greater variations associated with the sunspot effect.

The curve of the Lake Nyasa levels has been compiled from observations made at different periods and at different stations as follows:

1895–1914, Nkata Bay; 1914–1916, Monkey Bay;

1916–1924, The Bar, Fort Johnston. Fortunately, the Monkey Bay records overlap those of the other two stations. The first part of the curve, due to Captain E. L. Rhoades, is based upon observations representing for the most part only the approximate maximum and minimum readings for the year, whereas the last part is plotted from readings taken upon the sixth day of each month; nevertheless the relation of the lake levels to sunspot maxima and minima is clearly indicated. In view, however, of the imperfection of the data available, and also of the greater ratio of the annual variation to the "sunspot variation" as compared with Lakes Victoria and Albert, the correspondence between lake level and sunspot numbers is perhaps less satisfactorily indicated than in the case of these two more northerly lakes.

The following relationships as to lake levels and sunspots are evident from a comparison of the curves given in Fig. 1. The level of Lake Nyasa stood at a minimum during the sunspot minima of 1902 and 1913, and at or near a maximum during the sunspot maxima of 1895, 1906, and 1917; similar variations occur in the level of Lake Victoria and also in that of Lake Albert so far as the available records go. Owing to the slightly longer range of the Lake Nyasa records, the sharp rise preceding the maximum of 1895 is more clearly indicated for this lake than for Lake Victoria. Minor maxima in the lake levels occur in 1898, 1900, and 1910–11, two of them at least being clearly related to corresponding minor maxima in sunspot numbers.

An important difference exists between the Lake Nyasa curve for the period 1920–23 and the curves of the other lakes for the same period; while the fall following the maximum for 1917 ceased in the case of the former in 1920, it continued in the case of the latter for at least another two years. Moreover, early in 1924 the level of Lake Nyasa was higher than it had been at any time since 1898, and it appears probable that the maximum of 1898 will be reached or even exceeded in the near future. The explanation for these variations may perhaps be connected with exceptionally low level attained by Lake Nyasa about the end of 1914, during the last minimum, when it was lower than it had been for at least twenty years. The accompanying period of depression so much affected the Upper Shire river, which normally formed the outlet of the lake, that it became too feeble to remove not only the silt usually carried by it but also the detritus carried in by its tributaries; consequently, its bed became more and more silted up until coarse reeds and other forms of vegetation were firmly established upon it. Although the mean annual level of the lake stood more than four feet higher in 1923 than in 1914, and was still rising, the Upper Shire river remained impassable. Moreover, when the river begins to flow again with the first rains of the year, its direction of flow is now reversed, so that from a point about forty miles south of Fort Johnston the water actually flows towards instead of away from the lake. Since the gradient of this part of the valley of the Upper Shire has been given as about six inches per mile, this reversed flow indicates the rising of the river bed through a considerable height. The accumulation of sediment and of vegetation along the course of the river thus acts as a barrier impeding the discharge of water from the lake, and to this barrier may be ascribed the otherwise inexplicable rise of 1920–23 and afterwards. Further reference to the history of the Upper Shire river will be made in a later paragraph.

The conclusion already drawn from the Lake Nyasa curve that the lake level varies in sympathy with the sunspot numbers receives support from the general statements of early pioneers prior to the commencement of the actual measured record in 1895. The available data may be summarised as follows:

Date.	Lake Level.	Sunspots.
1830	Very low.	
1857–63	Very high.	Maximum about 186
1873	High.	Maximum about 187
1875–8	Falling; annual variation about three feet.	
1882	High.	Maximum 1883–4.
1890	Very low.	Minimum 1890.
1892–5	Rising rapidly.	Maximum 1895.

Marks on the rocks at Monkey Bay and elsewhe indicate that at some early period of unknown d the level stood six feet nine inches higher than 1897, which otherwise constitutes the highest recor level. According to native information, this old hi level period occurred not less than one hundred ye ago.

The diurnal variations of level to the extent about four inches, similar to those recorded from La Victoria, occur also on Lake Nyasa, and they m probably be ascribed to the same cause, namely, t influence of the land and lake breezes.

Recording piles have now been established at K Kota and Nkata Bay as well as at Fort Johnston, that there should be available for the future a m detailed and more complete record of the variatio of lake level than has been possible in the past.

The Upper Shire River.

Reference has already been made to the chan that have taken place in the Upper Shire river duri recent years. In the early history of the Protector the river formed an invaluable highway from t lake down to Matops, a distance of about ninety mile below Matops almost as far as Chikwawa the ri was rendered impassable by the Murchison Catarac Navigation for the larger lake steamers, drawi up to 6 feet of water, persisted at least until abo 1900, apart from occasional periods of low wat during which it was restricted to the upper reach of the river. From 1905 onwards, owing to a stea fall in the mean annual level of the lake, navigati on the river became more and more difficult, and t lower limit of navigation receded slowly up-strean about 1910 the river became too shallow even for sm craft, and from then until the present day the Upp Shire has been entirely useless as a waterway. the river fell and the accumulating silt enabled veg tation to become established and this in turn induc a more rapid deposition of sediment, large portio of the river-bed become swampy and ultimately dr Of late years, as has already been stated, when t river begins to flow with the first heavy rains of t year, it actually carries water for about forty miles in the lake instead of away from it. The accumulatio in the river bed have proved so firmly established ar so difficult of removal that the steady rise of the lal of the last few years has failed to give the riv sufficient power to clear them away; this is the mo remarkable when it is considered that not only h the level of 1905 been exceeded, but also that of 189 when the river traffic was at its height, is bei rapidly approached.

The remarks made as to the silting up of the Upp Shire apply also to the old Lake Malombe, throug which the river passed. The lake is now little bett than a large swamp, which is diminishing in are from year to year.

While an essential cause of the present silted-up condition of the Upper Shire was thus in all probability the steady fall of the level of Lake Nyasa from 1905 to 1914, other factors have probably acted as contributory causes. For example, during the last 60 years or more the Upper Shire valley, in common with other parts of the Protectorate, has been very largely deprived of its natural covering of vegetation; this has of course led to the rapid erosion of soil and even of sub-soil, particularly on the steep hillsides that form the valley walls. The streams flowing swiftly down from the hillsides have carried with them this eroded soil; on reaching the broad flat floor of the Upper Shire Valley, they have been forced to deposit their load in the main river and its larger tributaries. In this way the Upper Shire might well have received more detritus than it could dispose of, even apart from the added difficulty of diminished outflow from the lake. While it is true that the run-off from the hillsides has probably increased in speed and in amount, and should thus have helped to clear the debris, the combination in the main valley of a wide flat floor and steep walls has more probably overcome this factor and led to increased aggregation.

To whatever factor the blocking of the Upper Shire may be due, it is clear that it must bring about a rising of the level of the lake, although from the few figures at present available it appears unlikely that a rise of more than one foot per year at the most would result from this cause alone. In view of the larger variations of lake level due to other causes, however, it is practically certain that earlier or later an unusually high level of the lake would give the Upper Shire river a temporary advantage over the obstructions in its course. Once this advantage were gained the river would in all probability be able for a time to keep its course clear and thus assist in lowering the level of the lake; this process would gradually place the river in danger of becoming silted up again, when the cycle already outlined would begin afresh. It is of interest to note in this connexion that according to native tradition, as I am informed, the upper part of the Upper Shire valley is subject to periodical flooding on a large scale.

One other complication in tracing the history of the Upper Shire river is the possibility of the level of the land along the course of the river, or in the lake basin, having been slowly raised or lowered even within historical times. Certainly, within very late geological time, as proved by the existence of raised beaches, the lake stood several hundred feet above its present level; from the information at present available, however, it would be difficult to say whether the barriers that held the lake up to this great height have been removed by a tilting of the land or by some process of erosion similar to that described in the preceding paragraph. Attempts are now being made to determine how far available historical records indicate the existence of any such tilting. Certain it is that the strip of country along the line of the lake and the Upper Shire valley is in an unstable condition as compared with the country bordering it; this is evident from its late geological history and the frequent occurrence of earthquakes there even to this day.

Summary and Conclusions.

An examination of available records of the rise and fall of Lake Nyasa indicates that the level of this lake, in common with the levels of Lake Victoria and Lake Albert, varies in close sympathy with the number of sunspots; moreover, certain minor variations associated with sunspot phenomena are also common to all three lakes so far back as the records for each can be traced. While the rainfall records of the Lake Nyasa area are not sufficiently complete to be of value in this connexion, it has recently been shown that, in the case of Lake Victoria at least, a very high correlation exists between lake level and the rainfall of the surrounding plateau; thus the rainfall of the plateau is also closely related to the number of sunspots. Accordingly, in view of the sympathetic variation in the levels of Lake Nyasa and Lake Victoria, and the relation of the level of the latter lake both to sunspot maxima and to rainfall, it is more than possible that the level of Lake Nyasa and the rainfall of its catchment area as a whole may both attain to maximum values in parallel with the eleven-year periodicity of sunspot phenomena. It is of great interest in this connexion to observe that the great drought of 1921–22 affecting this part of Africa occurred in a period of sunspot minimum, that during this time the levels of Lake Victoria and Lake Albert were both falling at a considerable rate, and that the drought of 1911–12 also occurred in a period of sunspot and lake level minimum. Again, the Lake Nyasa maxima of 1896–8 and 1917 were immediately preceded by periods of exceptionally heavy rainfall. Finally, it has been observed by the older residents of Nyasaland that famines similar to those of 1912 and 1922 have occurred at intervals of ten or eleven years over a considerable period in the history of the country; thus it is not unreasonable to assume that famines will recur in the future at similar intervals, unless due precautions are taken to avert them.

As regards the level of Lake Nyasa, however, it appears that the condition of the Upper Shire river and its capacity for carrying off excess waters from the lake must act as an additional but irregular factor. The very low level attained by the lake in 1914, combined with certain other factors, led to such an extensive silting-up of the bed of the river that the succeeding maximum failed to give the river sufficient power to scour out its course. Consequently on passing the maximum the lake level fell but slowly; furthermore, it began to rise again, and rise rapidly, about three years before the anticipated minimum. By the early months of 1924 this rise had brought the level almost up to the high maximum of 1896–8 when river traffic was at its best, but even so the river remained practically dry and totally unfit for navigation. Hence during the next few years the lake may be expected to rise again at least to the highest level on record; if this rise enables the Upper Shire to remove the obstruction from its bed, the river may begin to assist again in bringing about a lowering of the lake level, and incidentally to become fit for navigation once more. The unexpectedly early and rapid rise of the lake that commenced in 1920, and even persisted through the drought of 1921–22, may thus be ascribed very largely to the virtual damming-up of the lake outlet by the prolonged accumulation of sediment and vegetation in the bed of the Upper Shire.

While fluctuations of considerable magnitude have occurred in the level of the lake during historic time, there is no evidence to show that any progressive rise or fall has taken place. This is in accord with the findings of a Commission recently appointed in South Africa to inquire into the cause of the disastrous droughts of recent years; it was found that there was no evidence for any progressive increase or decrease in the rainfall of the Union during historic time, and that the desiccation observable in many parts of the country was due, not to diminished rainfall, but to failure of the land to absorb the rain as it fell. The failure was regarded as due largely to the destruction of natural vegetation, to the consequent erosion of soil, and to the hardening of the surface of the land by sun-baking and the trampling of cattle.

A New Loop Galvanometer.

A NEW loop galvanometer made by the firm of Messrs. Carl Zeiss, of Jena, possesses several novel features. Although with its most insensitive arrangement it is capable of detecting a microampere, it is not easily damaged mechanically, and with a suitable field stand (Fig. 1) it can be used for taking out-

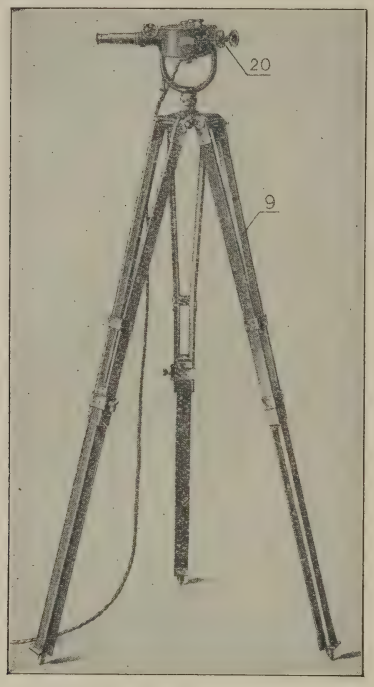

FIG. 1.—Galvanometer on field stand for outdoor observations.

door observations. In principle the instrument utilises the action of a magnetic field acting on a current carried by a light loop of metal foil. The magnetic field is produced by two strong permanent magnets the unlike poles of which face one another (Fig. 2).

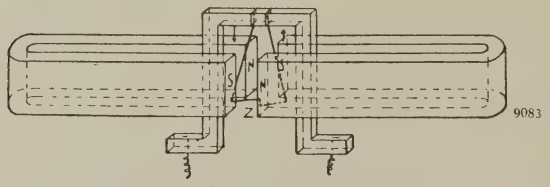

FIG. 2.—Diagram showing the arrangement of the magnets and the loop in its hanging position of stable equilibrium.

The sensitivity is therefore twice as great as when one magnet only is used. The internal resistance of the galvanometer is only about eight ohms.

The general appearance of the galvanometer is shown in Fig. 3. The deflexions of the loop are viewed through a microscope, having in its field of view a scale divided into 100 parts. For ordin purposes, daylight can be used to illuminate the lo When, however, greater sensitivity is required a supplementary microscope and a small electric la are employed.

The entire galvanometer casing is mounted trunnions, and by turning the whole instrum round, the loop can be used either in its sta position, where the sensitivity is least, or in unstable position, pointing vertically upwards, wh its sensitivity is about six times greater. The great sensitivity is about the hundredth part of a mic ampere. The loop is enclosed in a small glass box, a is thus protected from currents of air. When t current exceeds about the thousandth of an ampe the loop may cling fast to the glass sides. In t case tapping with the hand usually sets it free.

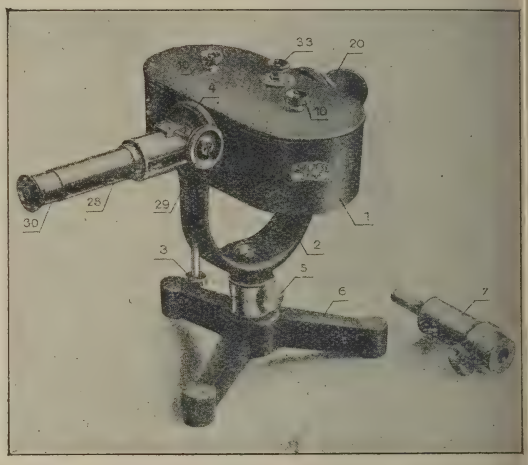

FIG. 3.—Loop galvanometer with microscope magnifying 80 times, f general laboratory and outdoor use. Sensitive to about 3×10^{-7} 6×10^{-8} amp.

small spring hammer, however, is provided outsid the box when more vigorous tappings are required When the loop is twisted up by an excessive curren it can be untwisted by a polished non-magnetic needl

All the optical arrangements for this instrumen are most interesting. The phenomena of interferenc bands are utilised; but this necessitates keeping th free surfaces of the optical parts very clean.

To the same degree of accuracy as with a mirro galvanometer, the deflexions are proportional to th strength of the current and they are aperiodic. A the internal resistance is very small, it is very sensitiv when used as a voltmeter. This type of galvano meter, however, is not so sensitive as a mirror, or a a string, galvanometer. In our opinion, its grea advantages lie in its robust construction, and in th fact that its internal resistance is small. It should prove useful for pyrometric and similar work.

Messrs. J. W. Atha and Co., of 8 Southampton Row W.C.1, are the London agents for Messrs. Carl Zeiss.

Some Aspects of Russia's Contribution to Chemistry.

PROF. W. P. WYNNE, in his presidential address to the Chemical Society (1924, 125, 997-1013), gives an extremely interesting account of the work of Russian chemists up to 1914, dealing mainly with the Kazan University school of chemistry. The history of this school begins with the appointment in 1835 of Claus, the discoverer of ruthenium, as its first professor of chemistry, succeeded two years later by Zinin, who remained in this position until transferred to Petrograd in 1848. To this worker we owe the discovery of some of the fundamental reactions of aromatic organic chemistry,

sch as the preparation of aniline, α-naphthylamine, -phenylenediamine from the corresponding nitro-mpounds by reduction with ammonium sulphide, also the production of azoxybenzene, azobenzene d benzidine by modification or development of e above process.

Butlerov, who succeeded Zinin, is remarkable, t only for his far-reaching researches in the field structural chemistry and for the introduction of merous fundamental conceptions now universally ployed in the theory of organic chemistry, but so for his influence in forming an entire school of emists who, up to the present day, have actively llowed up and enlarged upon his work. Butlerov's st paper deals with the preparation of trioxy-ethylene and hexamine, and it was in the course this work that the first clue to the possible mechan-m of sugar synthesis in plants was found, namely, ie preparation of a mixture of hexoses from trioxy-ethylene. In the course of his next investigation isomerism and isomeric changes, Butlerov sug-ested the possibility of the phenomenon of tauto-erism which was later to occupy so prominent a lace in organic chemistry, and incidentally explained ie nature and the importance of the zinc methyl eaction, which, as a result of this work, occupied prominent place in processes of synthesis, until perseded by the Grignard reagent. A further con-equence of this work was the demonstration of the ossible stability of compounds possessing two ydroxyl groups attached to the same carbon atom, nd this was further substantiated by the synthesis f pinacolin from trimethylacetyl chloride. The xplanation of the course of reactions of polymerisa-ion in the olefine series must also be attributed to Butlerov, and it is noteworthy that in his investiga-ion on the di*iso*butylenes he again puts forward he idea of tautomerism.

Among the numerous workers who received their nspiration from Butlerov, perhaps the best known s Markovnikov, the enunciator of the well-known ule which bears his name. His work on the naph-henes is, however, no less important to chemistry han the above rule, and furnishes a classic example f the perseverance and capability of overcoming ifficulties so characteristic of Russian chemists. This research, together with those of Wreden at Petrograd and Kijner at Moscow, were instrumental n placing the study of the alicyclic compounds on he same level as that of other hitherto better known ubstances.

Markovnikov was succeeded in 1871 by A. N. Saytzev, who remained as professor of chemistry at Kazan until his death in 1909. Much of Saytzev's work was a continuation of his predecessors', dealing with the systematic synthesis of alcohols by the zinc alkyl process. G. Wagner is probably the most brilliant of Saytzev's students. This worker extended Saytzev's method for the preparation of secondary alcohols from ethyl formate by substituting for the latter various aldehydes, thereby obtaining ketones, which served as material for the testing of Popov's rule as to the oxidation of ketones. As a result of this work, Wagner was able to show that this rule did not hold good in all cases, but had to be modified according to circumstances. Following up this research, he next studied the progressive oxidation of compounds possessing ethylenic bindings and showed the importance of oxidation reactions in locating the position of unsaturated linkings in olefinic chains. In this way he was able to assign to oleic acid the structural formula now accepted. A consequence of this work was the view that oxidation of fatty acids occurs in the β-position, thus anticipating by sixteen years Knoop's theory of β-oxidation. The application of these oxidation methods to the study of the terpenes occupied the last twelve years of Wagner's life, and enabled him to assign to pinene, terpineol, dipentene, bornyl chloride, bornylene, and camphene their respective formulæ.

Similar work to that of the Kazan school was in the meantime also being carried out at Petrograd, Moscow, and Kiev, where Ipatiev, Zelinski, Favorski, and others studied the reactions of unsaturated hydrocarbons. Ipatiev was the first to synthesise isoprene by a method which gave clear evidence of its structure, and is also known for his work on the structural changes occurring in the unsaturated hydrocarbons obtained by the catalytic dehydration of alcohols. Zelinski investigated the *cyclo*-paraffins and olefines, whilst Favorski was the discoverer of the change which the homologues of allylene undergo on heating with alcoholic caustic alkalis. Kutcherov was the discoverer of the catalytic conversion of homologues of acetylene into aldehydes and ketones, thus opening the way to the production of acetic acid from carbide.

Mendeléeff is undoubtedly the best known of Russian chemists, and his paper on the periodic classification of the elements is too well known to require description, and the same may be said of the work of Beilstein and Menschutkin.

Prof. Wynne closes with a plea for a better appreciation of the value of the Journal of the Russian Physical-Chemical Society, and suggests that a study of this journal would amply repay the trouble incident on acquiring a sufficient knowledge of Russian.

The Kerr Effect in Optically Active Liquids.

WHEN polarised light passes through an optically active liquid in an electrostatic or a magnetic field the phenomenon of double refraction observed with a non-active substance is complicated by the optical rotation, and the only method employed to study the birefringence has been to mix equal quantities of right- and left-handed samples of the compound to be investigated, so as to obtain a non-active liquid. M. R. de Mallemann, in the *Annales de Physique* for July-August, making use of the Airy-Gouy principle that on the element of path *dl* the double refraction and the rotation act independently of one another, and that the resultant effect can be calculated by compounding the elementary vectors representing the two effects, derives formulæ by means of which the true double refraction of the liquid can be derived from the observations. Measurements are described on pinene, turpentine, ethyl tartrate, carvone and camphor, in which Panthener's method of instantaneous charge was used, which, in spite of certain difficulties, gives fairly satisfactory results in all cases, and enables the birefringence of imperfect insulators to be determined.

In almost all cases the Airy-Gouy principle gives, qualitatively, the relation between the phenomena; and, in general, there is quantitative agreement even with bodies like carvone, which have very large birefringence, the calculated ellipticities not differing in the majority of cases from those observed by amounts exceeding the limits of precision of the measurements. For the rotation of the axes, however, the differences in the case of carvone are more systematic.

M. de Mallemann considers the theories of Stark,

Oseen and Born, in connexion with his own previous work, which explained optical activity in terms of the asymmetry of the molecule; he does not, like the above authors, assume resonance, but uses the single idea of the asymmetry of the field of force, taking into account the experimental data. The theory indicates, in apparent agreement with observation, that the rotary power should increase when the number of atoms is large, when the masses and atomic volumes are large, and when the atoms are arranged very unsymmetrically. It also shows that the rotary dispersion is related to the refractive dispersion; and the specific rotary power should, in general, diminish with increase of temperature, and should increase with the pressure. There are, however, certain discrepancies in passing from the liquid state to that of vapour. Modifications of the molecular structure due to lack of rigidity of the molecule, which would not affect the refractive index, may produce marked changes in the optical activity, and the rotary power must be a very delicate index of molecular phenomena. This accounts for the difficulty of finding simple laws connecting the phenomenon as observed in different substances. The theory indicates that the Airy-Gouy formula can no longer hold rigorously for high refractivity; apparently this commences to be true in the case of carvone.

Engineering and Shipbuilding.

IT is not easy to state reasons for the present depression in the engineering and shipbuilding trades without touching upon political matters, and both Mr. J. Howden Hume and Mr. Tom Westgarth found this difficulty in their presidential addresses to the Institution of Engineers and Shipbuilders in Scotland and the North-East Coast Institution of Engineers and Shipbuilders respectively. Still in both addresses there is much of interest and several valuable suggestions.

Mr. Hume attributes the depression to (*a*) the loss of our export trade; (*b*) the Washington Treaty, which has seriously affected not only workmen engaged in engineering and shipbuilding, but also those on the technical and scientific staffs, and those connected with allied trades, besides the artisans in districts where warship building was carried out; (*c*) the world's market on the merchant shipping side has partially collapsed, and there was over-production of merchant ships during and immediately after the War.

Mr. Hume suggests (i.) that the whole question should be taken out of the political field and placed in the hands of a representative body, chosen, say, by half-a-dozen of the leading judges, and comprising equal numbers of manufacturers, workmen, merchants, and professional men. Such a body would arrive at the truth, and a plan could be devised and acted upon by the Government in power. (ii.) A complete and friendly understanding between employer and employed. The Shipping Federation and the National Sailors' and Firemen's Union have worked together for thirteen years, and in that time there has been no strike in the shipping trade. Other bodies might follow this lead.

The subject of Mr. Westgarth's address was waste. Of all sources of waste in industry, the greatest is that caused by strikes and lockouts, by demarcation difficulties between trades, and by people of all classes not doing a fair day's work for a fair day's pay. Many disputes are the result of neglect and delay in dealing with difficulties as they arise, and something of the old-fashioned discussion between master and workmen immediately a difficulty appears should be revived. Such discussion should be informal and n binding on the official representatives of either sid By this method a great many disputes would probab never be taken outside the works. In 1921, 85,872,0 working days were lost through disputes, a 10,642,000 in 1923, according to the Ministry Labour Gazette. Nearly all this waste is preventabl and could be prevented by friendly conference. S Robert Hadfield's suggestion that an endeavo should be made to arrange an industrial truce worthy of the most serious consideration.

Mr. Westgarth referred to a fruitful cause of unrest wages in the so-called protected trades do not co pare reasonably with those in the highly skilled an competitive trades. If competition in the ope markets of the world makes it impossible to pa skilled workmen a certain wage, it is in the highe degree wasteful to pay considerably higher wages t unskilled men just because a stoppage of their wor would be an inconvenience to the public. This reall amounts to a kind of blackmail, and the public shoul be assisted in resisting such claims by their governin representatives.

In reference to technical waste, Mr. Westgarth say that the engineering industries can only be success fully conducted nowadays by helping to make possibl the discovery of new methods of manufacture an fostering the advancement of new ideas in engineerin science—as distinct from teaching engineering scienc —and then by giving commercial expression to th best of such methods and ideas. Has such a polic been characteristic of British engineering? Th future of British engineering will be good or bad according as the spirit of scientific progress develop or flags.

Electrical Precipitation.[1]

THE two kinds of electrical precipitation dealt with were the natural and the artificial. Artificial precipitation began with the well-known experiment which Sir Oliver Lodge showed to the British Association at Montreal in 1884 on the electrical deposition of smoke or steam; an observation which has now been applied on a large scale in Great Britain, by his sons and by Dr. Cottrell in the United States, to the recovery of metallic fume, and to the freeing of blast-furnace gas from solid material before combustion. The theory of the action is like that of the coherer, and was considerably elucidated by the late Lord Rayleigh's experiments on the cohesion of liquid jets and drops, under slight electrical stimulus.

The natural kind of electrical precipitation is what occurs in the atmosphere when clouds turn into rain; and also when, as shown by Dr. G. C. Simpson, large water-drops break up in a column of ascending air, giving rise to separation of electricities and the phenomenon of thunderstorms. This mode of generating electricity is somewhat surprising. A theory of it is suggested by the coherer and water-drop experiments; since the breaking-up of a drop may be regarded as the converse action to the cohesion of two drops. Electrical influence stimulates cohesion: it is possible that absorption may give rise to electrical separation. Not that the two fragments become oppositely electrified, but because the uniting electronic layer is blown away by the air, thus carrying away a negative charge and leaving the residual water positive. Calculation applied to this phenomenon seems to give results of the right order of magnitude, making use of Dr. Simpson's measurements of the charge which can thus be imparted to the fragments

[1] Abstract of an address by Sir Oliver Lodge, F.R.S., delivered on Wednesday, October 29, to the Institute of Physics.

a drop of water of known size, falling through or to a blast of air.

Returning to the artificial electrification of solid or liquid particles, Sir Oliver emphasised the engineering skill which had enabled very high-tension electricity to be applied, in difficult circumstances, continuously throughout the year; and mentioned the economical value of the results. He then proceeded to ask whether the natural operations occurring in the atmosphere would always remain beyond human control; or whether precipitation of moisture could not be taken in hand and managed—in ways which seemed no more difficult or unmanageable than the modern theory and treatment of disease; a subject which, like the weather, was at one time left to pious resignation or appeal, without any adequate effort being made to take it in hand and control it.

University and Educational Intelligence.

CAMBRIDGE.—Lady Teall has presented to the Sedgwick Museum the very valuable collection of rocks and rock-slices made by her late husband, Sir Arthro Teall, St. John's College.

Dr. M. B. R. Swann, Gonville and Caius College, has been reappointed demonstrator of pathology.

Mr. F. P. Ramsey, Allen student and scholar of Trinity College, has been elected to a fellowship at King's College.

The Henry Sedgwick Memorial Lecture will be given at Newnham College by Sir J. J. Thomson, Master of Trinity College, on Saturday, November 29, at 5 o'clock. The title of the lecture is "Radiation."

LONDON.—A University chair of anatomy, tenable at the Middlesex Hospital Medical School, has been instituted as the result of a munificent gift of 20,000*l.* by Mr. S. A. Courtauld; the title of the chair will be "The S. A. Courtauld Chair of Anatomy"; and Dr. Thomas Yeates, at present University professor of anatomy at the School, has been appointed as the first occupant.

The Sir John William Lubbock Memorial Prize in mathematics, of the value of 30*l.*, has been awarded to Miss E. M. Jones, of the Royal Holloway College.

The following doctorates have been conferred: D.Sc. (*Physics*): Mr. W. N. Bond (University College and the Imperial College—Royal College of Science), for a thesis entitled "The Flow of Fluids treated Dimensionally"; D.Sc. (*Chemistry*): Mr. G. E. Foxwell, for a thesis entitled "Collected Researches into By-Product Coking," and another paper; and Miss F. M. Hamer, for a thesis entitled "The Synthesis of an Azocyanine," and other papers.

Prof. H. B. Baker has been appointed representative of the Faculty of Science on the Senate for the remainder of the period 1921–25 in succession to Prof. A. N. Whitehead, who has accepted a chair in the Faculty of Philosophy at Harvard University.

APPLICATIONS are invited for the Wernher Beit chair of pathology in the University of Cape Town. The applications, eight in number, should be sent by, at latest, November 18 to the Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2.

A LECTURER in mechanical engineering is required at the University of Cape Town for twelve months dating from March 1 next. Candidates must be qualified to give instruction on machine drawing and design and the theory of machines. Applications should be sent by November 7 at latest to Prof. Gillick, Royal College of Science, South Kensington, S.W.7.

APPLICATIONS are invited for the principalship of the Wigan and District Mining and Technical College in succession to Mr. S. C. Laws, recently appointed principal of the Northampton Polytechnic Institute, Clerkenwell. The latest date for the receipt of applications is November 29. They should be sent to the chairman of the governing body of the college.

THE council of the Royal Horticultural Society has decided to contribute 105*l.* to the fund which Lord Milner is raising for the Imperial College of Tropical Agriculture. This is a gratifying indication that the premier horticultural society in the world recognises the value of the work that the College is doing for agriculture in the tropics.

A LECTURER in psychology and philosophy will be required in February next at the Rhodes University College, Grahamstown, South Africa. Particulars may be had from the Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2. Applications for the post should be sent not later than November 5 to the Master, Balliol College, Oxford.

THE North of Scotland College of Agriculture Calendar for 1924–25 includes reports on the past year's work, showing that the county extension classes were well attended. The rapid development of the work is shown by the record of attendances during each of the past five years at the systematic classes in agricultural subjects in the extension area of the College: 3035, 13,166, 18,786, 23,436, 33,849. The Central Class report, on the other hand, shows a decrease in the enrolments for degree courses in all subjects except agricultural botany and agricultural zoology. The Edinburgh and East of Scotland College of Agriculture also shows a decrease in the number of students attending Central Classes under each of the heads: day classes, evening classes, rural schools' course, and farmers' class. The College has now entered into possession of its experimental farm of 600 acres at Boghall, and the publication of college reports and leaflets, which has for some time been discontinued, will, one may surmise, be resumed. The list of appointments held by former students shows that appointments were obtained in 1923 in Scotland (2), England (2), Ireland, Hungary, West Africa, Tanganyika, India, Singapore, and Argentina.

HONOURS courses have been established recently in many American universities and colleges with the object of releasing the more highly gifted undergraduates from the trammels of a system designed to meet the needs of the average student. The National Research Council collected material in the shape of reports and suggestions and turned it over to President Aydelotte, of Swarthmore College, who has prepared a critical summary, published by the Council as Bulletin No. 40. In thirty colleges and universities, honours candidates are now required to undertake specific extra tasks, a special course, a thesis, or a comprehensive examination, in addition to doing substantially the same amount of work in regular courses as is done by the pass-men. In nine there are, or will shortly be, in operation schemes for honours based on work superseding the regular requirements during a part, generally the third and fourth years, of the undergraduate course, following a creditable record in the work of the first two years. The honours student has his work outlined for him, not, like the pass-man, in terms of what he must do, but in terms of what he must know. Instead of taking courses he studies a subject. In nearly all cases provision is made for individual supervision and instruction by competent teachers, but not for any great number of special honours lectures or classes.

Early Science at the Royal Society.

November 2, 1664. Dr. Wilkins related that Sir John Cutler had declared to him, that he was firm in his resolution to settle upon Mr. Hooke 50*l.* per annum for such employment as the Royal Society should put him upon.—A letter of Mons. Huygens to Sir Robert Moray was read, containing a relation of his having seen with wonder at Paris a glass of twelve foot of the workmanship of Divini, which bore the aperture of two inches Parisian measure; upon which occasion he recommends it as a matter worthy of inquiry, to know what may be the right aperture in each glass, of such and such a distance from the focus.

1671. Mr. Oldenburg presented to the Society from Mr. Hobbes his "Rosetum Geometricum," printed at London, addressed by him to the Royal Society for their judgment thereon: Which pieces were referred to the consideration of the professors of Astronomy and Geometry in Gresham-college, and Mr. Collins.

November 4, 1663. The history of whale-fishing, and of the making of whale-oil, was delivered in by the secretary from Mr. Gray of the Greenland Company, who had been in those parts, and was present at the killing of whales and the making of oil.

November 5, 1667. It was mentioned by Mr. Oldenburg, that Sir Paul Neile had spoken to him, that Mr. Adrian May had desired, that the society would give order for a good thermometer for the use of the Queen.—Dr. Wilkins moved, that Mr. Collins might be declared exempt from the payment of admission-money and the weekly payments, he having but a small revenue, and being capable and willing to do the Society very good service. He was declared exempt accordingly.

November 6, 1672. Mr. Hooke mentioned that among Mr. Guericke's experiments there was one which he thought deserved to be tried before the Society, viz., that of a sulphur-ball having a considerable attractive power, and representing the properties of the earth. Mr. Locke intimated that himself had made some experiments with such a ball.

1673. The earl marshal, who was present was acquainted by the council with their thoughts of removing their weekly assemblies to Gresham College, and of beginning to meet there again upon the next anniversary election-day; as also by the solemn invitation of the city of London, and the professors of Gresham College. To which was added, that though this Society should thus remove their meetings, yet they were full of hopes that his lordship would be so far from removing his favours and kindnesses from them, that he would preserve them in the same degree that he had done all along, and especially during the many years he had entertained them under his roof. Whereupon the earl marshal very obligingly and generously declared that though they had been a great honour to his roof, he could not but give up his reason to the reason of the council.

November 7, 1666. Sir Robert Moray proposed, that the directions for seamen, and the inquiries of tides, might be printed separately, and the instruments mentioned in the printed papers concerning these particulars provided both at the society's expence; and promised, that he would endeavour to procure an order from his Royal Highness the duke of York to Trinity-house, importing, that every captain and master of a ship should take with them in their voyages a copy of such printed books, and make observations and trials accordingly; of which they should at their return give one to Trinity-house, and another to the society.

Societies and Academies.

LONDON.

Royal Meteorological Society, October 15.—M. C. J. P. Cave, president, in the chair.—L. F. **Richardson**: The brown corona and the diameters of particles. As a result of experiment the following variety of Airy's formula has been found to be in rough agreement with measurements on various holes and spheres:

$$\text{(diameter of obstacle)} = \frac{5{\cdot}3 \times 10^{-5}\ \text{cm.}}{\sin\left\{\text{(radius of chestnut-brown corona)} - \tfrac{1}{2}\text{(radius of source)}\right.}$$

In view of Ray's work this will not be applicable to the smallest cloud-droplets of 2 microns diameter but is more likely to apply to drops of ordinary size, of, say, 5 to 20 microns diameter.—L. F. **Richardson**: Photometric observations on clouds and clear skies. With an improved instrument made at Benson, it was shown that the difference-of-brightness at the moon's-limb, as measured by the instrument, is independent of the glow of the sunlit sky. It was also shown that the transparency of blue sky alters during twilight. Observations on clouds enable one to compute the rainfall equivalent to the cloud on those occasions when a corona reveals the size of the droplets; a certain very dark thunder-cloud was like a rain-factory holding in stock only one hour's output.—L. J. **Sutton**: Notes on haboobs. Haboobs are severe sandstorms of a type apparently confined almost entirely to the Sudan, where they are most frequent in the central region. Nearly all of them occur during the rainy season, *i.e.* May to October, and at Khartoum, for example, they are experienced more than once a week during this period and last about three hours on the average. Haboobs probably owe their origin to the heating up of a large region for four or five days, but owing to the wide distances between meteorological stations in the Sudan, it has not been possible to discover where any particular haboob originated or to follow its track.

MANCHESTER.

Literary and Philosophical Society, October 21.—G. **Senn**: The change of position of the chlorophyll grains in the plant cell. Green chlorophyll grains show positive and negative phototactic reactions to red and green light, if it is strong enough or if the sensitiveness of the grains is raised by lower temperature. The various colouring substances appearing in the chlorophyll grains of different Algæ (yellow in diatoms, brown in Brown Algæ, and red in Red Algæ) generally do not influence their phototactic irritability. A Red Alga was only slightly more sensitive to green light of diffuse intensity. In high intensities of direct sunlight the red rays induce a very strong effect on the grains of the majority of Brown Algæ (five of six species) and of the only Red Alga studied. But as the yellow light with its shorter rays produced much weaker effects, the strong action of the red rays must have been produced by a damaging action on the protoplasm which transported the grain by its streaming. In this case the grains are passive during their movement like those of Elodea and Vallisneria during the rotation of the protoplasm. It seems that it is only the colourless protoplasmic strands of the envelope of the green chlorophyll grains which execute their normal movements.

PARIS.

Academy of Sciences, September 29.—M. Louis Bouvier in the chair.—Mme. Sylvia **Creanga**: The cyclifying developable surfaces of a curve and

their application to the theory of curves traced upon a surface.—Th. **Varopoulos**: The differentials of multiform functions.—A. **Foch**: The use of Recknagel's disc as an indicator of velocity and direction. Predetermination of the constant for a Recknagel's disc and suggestions for possible applications.—J. G. **Stokvis**: Conversion of the energy of a triphase system or a constant energy to a pulsatory energy.—André **Léauté**: The propagation of electric waves along perfectly insulated iron wires, taking account of the skin effect.—H. **Gault** and H. **Klees**: Contribution to the study of the condensation of acetoacetic esters with malonic esters. Preliminary results of the products of the interaction of α-chloracetoacetic ester with the sodium derivatives of cyanacetic ester and of malonic ester.—G. C. **Georgalas**: The geological constitution of the Phourni Islands (between Nikaria and Samos).—**Munerati**: The running to seed of beetroot in the first year. The conditions under which the beetroot may behave as an annual or a biennial are not known with certainty and are not under control. Examples are given of the slight changes in external conditions which may cause the change from annual to biennial.—Jacques **Benoit**: Experimental endocrinian hypomasculism in the domestic cock.—Jean **Bathellier**: The development of *Macrotermes gilvus* compared with that of *Eutermes rantangensis*.—**Parat** and J. **Painlevé**: Vital observation of a glandular cell in activity. The nature and rôle of Golgi's internal reticular apparatus and Holmgren's apparatus.

October 6.—M. Louis Bouvier in the chair.—P. **Villard**: The experiments at Courtine. The dominant waves produced by a very powerful explosion are, even at a short distance, of very low frequency, well below the audible limit: the sound is the result of a secondary phenomenon of relatively negligible importance. It is quite certain that the mechanical effects, such as breaking windows, observed in the neighbourhood and up to several kilometres distance from a powerful explosion, must be attributed to waves much longer than the ear can perceive.—G. **Sagnac**: The mechanism of light projection in double stars.—A. **Grumbach**: The rôle of ionisation in cells with fluorescent liquid.—Charles **Nordmann**: The utilisation of the grapho-mechanical combiner for numerous everyday problems in physics.—W. **Kopaczewski**: The effects of dilution on colloids. In determining the physico-chemical constants of blood serum, it has been found that the diluted sera possess a conductivity sensibly higher than would be expected from the law of electrical dissociation. Other colloids (hæmoglobin, collargol, electrosol of calysed silver and gold, Paris violet, etc.) have now been examined and have proved to show the same phenomenon. Some consequences in physical chemistry, biology, medicine and therapeutics are deduced.—E. **Darmois** and A. **Honnelaitre**: Some properties of ammonium dimolybdomalate. This salt is a reagent for substances capable of combining with molybdic acid: these produce considerable variations in the rotatory power.—A. **Lassieur**: The electrolytic separation of copper, antimony, and bismuth from lead. The separation is effected in hydrochloric acid solution, with or without addition of hydrofluoric acid, in the presence of hydroxylamine hydrochloride, and using the method of graded potentials.—Mme. Pauline **Ramart**: The action of hydrobromic acid on some tertiary alcohols. Alcohols of the general formula $(C_6H_5)(OH)(Ar) . C . CR_1R_2R_3$ are readily transformed into unsaturated hydrocarbons by the action of HBr in glacial acetic acid solution.—**Fosse** and A. **Hieulle**: A colour reaction, hitherto supposed to be characteristic of formaldehyde, produced by glyoxylic acid.—Marcel **Mirande**: The states of liliosterin in the course of the life of the bulbar scales of the white lily.—P. **Reiss**: Remarks on the internal P_H of the cell nucleus and its experimental variations.

ROME.

Royal Academy of the Lincei.—Papers received during the vacation.—Giacomo **Albanese**: Conditions for the rationality of the variety of pairs of points of two distinct or coincident algebraic surfaces.—Luigi **Fantappiè**: The nth prime number as the asymptotic value of a function $\psi_n(s)$ deduced from the $\zeta(s)$ of Riemann.—Oscar **Zariski**: Algebraic equations containing linearly a parameter and resolvable by means of radicles.—Bonaparte **Colombo**: An extension of Lamé's problem regarding the distribution of temperature in an ellipsoid having three unequal axes.—Washington **Del Regno**: Relation between the elastic tension and the magnetic behaviour of nickel steels in the neighbourhood of the transformation point. The relationship between the elastic and the magnetic behaviour shown by nickel is found also with three nickel-iron alloys, two of these being reversible and the other irreversible.—S. **Berlingozzi** and G. B. **Capuano**: 3-Hydroxyquinoline-4-carboxylic acids.—F. **De Carli**: Reducibility of certain metallic halides by means of hydrogen.—Remo de **Fazi**: A new reaction of aldehydes.—G. **Malquori**: Electrolytic preparation of ozone by means of an alternating current superposed on a continuous current.—Emilio **Papasogli**: Derivatives of diphenylamine.—Mario **Passerini**: Reaction between pernitrosocamphor and potassium cyanide. This reaction is one of direct addition of a molecule of each of the reacting compounds, the result being a potassium salt, the potassium of which may be replaced by other elements, such as copper or silver.—Ubaldo **Sammartino**: Studies on insulin: II. Action of insulin on zymase. The experimental results obtained lead to the conclusion that the active principle of the pancreas exerts no appreciable influence either on the fermentation of sugars by Saccharomyces or on glucolysis by zymase.—V. **Tognazzi**: Chalkones and hydrochalkones.—Mario **Ferrari**: Datolite from Monte Campotréra (Reggio Emilia).—Roberto **Savelli**: Transmission of mutations through inter-specific hybridisations.—Livia **Garofolini**: Utilisation of *Triton cristatus* for the destruction of the larvæ of Anopheles. *Triton cristatus* destroys, but is not a specific enemy of, Anopheles larvæ.—Luisa **Volterra**: Variability of the pelagic Daphnias of the lakes of Albano and Nemi.—G. **Amantea**: Periodic and cyclic modification of the uterus of Canis, independent of pregnancy.

SATURDAY, NOVEMBER 1.

GILBERT WHITE FELLOWSHIP (at Queen Square, W.C.), at 3.—Sir A. Daniel Hall: The Countryside in English Literature (Presidential Address).

MONDAY, NOVEMBER 3.

ROYAL SOCIETY OF EDINBURGH, at 4.30.

ROYAL INSTITUTION, at 5.—General Meeting.

SOCIETY OF ENGINEERS (at Geological Society), at 5.30.—Capt. W. J. Liberty: Underground London.

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Public Library, Swansea), at 6.—R. G. Isaacs and others: Discussion on Power Factor Improvement.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.—H. H. Harrison: Chairman's Address.

ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street, W.C.), at 8.—Prof. A. D. Lindsay: What does the Mind construct? (Presidential Address).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—W. J. U. Woolcock: Experiments in Protection.

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (at Leicester Museum), at 8.—Prof. H. H. Swinnerton: Man 100,000 B.C.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.30.—Presidential Address.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Sir Aurel Stein: Innermost Asia: Its Geography as a Historical Factor (First Asia Lecture).

TUESDAY, NOVEMBER 4.

ROYAL HORTICULTURAL SOCIETY, at 4.—Lecture.

MINERALOGICAL SOCIETY (at Geological Society), at 5.30.—Anniversary Meeting.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—C. M. Hunter: The Oilfields of Argentina.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Sir A. Smith Woodward: Exhibition of a Plaster Cast of a Fossil Egg of a Dinosaur.—D. Seth-Smith: Exhibition of Rare Amazon Parrots from Dominica and bower of Australian Regent-Bird.—S. Hirst: Three new Acari belonging to the Superfamily Trombidioidea (Erythræidæ and Teneriffiolidæ).—I. Montagu: (1) The Remains of Fen-Beaver in the Sedgwick Museum; (2) The Burrows of the Rodent Spalax.—R. Gurney: The Larval Development of some British Prawns (Palæmonidæ). II. *Leander longirostris* and *Leander squilla*.—W. E. Le Gros Clark: The Brain of the Tree-Shrew, *Tupaia minor*.

INSTITUTION OF CIVIL ENGINEERS, at 6.—B. Mott: Address.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at Midland Hotel, Manchester), at 7.—H. C. Lamb: Chairman's Address.

INSTITUTE OF METALS (Birmingham Section) (at Chamber of Commerce, New Street, Birmingham), at 7.—A. R. Page: Brazing.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. D. Johnston: Presidential Address.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Section) (at Broadgate Cafe, Coventry), at 7.15.

INSTITUTE OF METALS (North-East Coast Section) (at Armstrong College, Newcastle-on-Tyne), at 7.30.—W. E. W. Millington: The Structure of Metals in its relation to Elastic Failure. Part II.

RÖNTGEN SOCIETY (at British Institute of Radiology, 32 Welbeck Street, W.), at 8.15.—Dr. A. E. Barclay: The Growth of Radiology: Has the Röntgen Society kept pace with it? (Presidential Address).

WEDNESDAY, NOVEMBER 5.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Prof. F. X. Schaffer (of the State Natural History Museum, Vienna): History of the Vienna Basin (Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—E. H. Shaughnessy: Address.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at Engineers' Club, Coventry Street, W.), at 7.—E. S. Shoults: The Heating and Ventilation of Glass Houses from the Grower's Point of View.

SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section) (at University College, Nottingham), at 7.30.—C. E. Pickard: The Testing of Bates in the Laboratory.

ROYAL MICROSCOPICAL SOCIETY (Biological Section), at 7.30.—W. S. Hoseason: Notes on the Malaria Parasite.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—Dr. H. E. Cox: Certain New Methods for the Estimation of Arsenic and its Occurrence in Fish and Urine.—A. T. Etheridge: The Estimation of Cadmium in Brass.—N. C. Wright and J. Golding: The "Hoyberg" Method of Milk and Cream Testing.—Dr. S. G. Willimott: An Apparatus for the Catalytic Dehydrogenation of Alcohols.

ROYAL SOCIETY OF ARTS, at 8.—Senatore G. Marconi: Address.

INSTITUTION OF CHEMICAL ENGINEERS (at University College), at 8.—Dr. M. W. Travers: The Water Gas Process.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

THURSDAY, NOVEMBER 6.

ROYAL SOCIETY, at 4.30.—Prof. T. R. Merton: Ultraviolet Spectrophotometry.—Prof. W. L. Bragg and Prof. S. Chapman: A Theoretical Calculation of the Rhombohedral Angle of Crystals of the Calcite Type.—Prof. O. W. Richardson and T. Tanaka: (1) The Striking and Breaking Potentials for Electron Discharges in Hydrogen; (2) On A, P, Q and R Combination in the Many Lined Spectrum of Hydrogen.—J. D. Bernal: The Structure of Graphite.—*To be read in title only*:—C. N. Hinshelwood and R. E. Burk: The Homogeneous Thermal Decomposition of Nitrous Oxide.—C. N. Hinshelwood: The Kinetics of the Interaction of Nitrous Oxide and Hydrogen.—Dr. A. T. Doodson: Perturbations of Harmonic Tidal Constants.—K. R. Ramanathan: The Structure of Molecules in relation to their Optical Anisotropy. Part I.—Prof. J. W. Wood: Controlled Orbital Transfers of Electrons in Optically Excited Mercury Atoms.

LINNEAN SOCIETY OF LONDON, at 5.—E. G. Baker: A Remarkable Tree of African Leguminous Plant.—Prof. E. B. Poulton: Exhibit of Lantern Slides illustrating Mimicry among Fijian Butterflies.—Dr. H. A. Baker: Cestodes from Whales.—W. H. Pearsall and Dr. W. H. Pearsall: Phytoplankton of the English Lakes.—Dr. B. M. Griffiths: Studies in the Phytoplankton of the Lowland Waters of Great Britain: the Phytoplankton of Shropshire, Cheshire, and Staffordshire.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Sir St. Clair Thomson: Tuberculosis of the Larynx and its Significance to the Physician (Mitchell Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—R. Johnson: Some Clinical Aspects of Carcinoma of the Breast (Bradshaw Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—J. D. Cockcroft, E. Coe, J. A. Tyacke, and Prof. Miles Walker: An Electric Harmonic Analyser.

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates' Meeting) (at Westminster House, Adelphi), at 7.30.

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (Joint Meeting with the Institute of Chemistry) (at Bristol University), at 7.30.—F. Holmyard: The Present Position of the Geber Problem.

CHEMICAL SOCIETY, at 8.—J. Kenyon, H. Phillips, and H. G. Turner: Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XXIV. Further Experiments on the Walden Inversion.—Prof. T. M. Lowry: Studies of Valency. Part V. The Mechanism of the Walden Inversion.—H. J. Emeléus and W. R. Downey: A Spectroscopic Study of the Luminescent Oxidation of Phosphorus.

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section), at —Joint Discussion with the Section of Epidemiology and State Medicine and the Society of Medical Officers of Health, on The Notification of Puerperal Sepsis.

INSTITUTION OF MECHANICAL ENGINEERS (Glasgow Section) (at Glasgow). —Prof. J. H. Andrew: Steels and their Selection.

INSTITUTION OF MECHANICAL ENGINEERS (Manchester Section) (at Manchester).—Prof. W. T. David: (*a*) The Missing Pressure in Gas-Engine (*b*) Heat Loss in Gas-Engines.

FRIDAY, NOVEMBER 7.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Geophysical Discussion: International Geophysical Congress at Madrid. Chairman—Col. H. Lyons. Speakers—Sir G. P. Lenox-Conyngham, A. R. Hinks, Dr. Chree, R. G. K. Lampfert, Prof. H. H. Turner.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Vice-Admiral Sir George G. Goodwin: The Trend of Development of Marine Propelling Machinery (Thomas Hawksley Lecture).

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at 16 St. Mary's Parsonage, Manchester), at 7.—Sir William Willcox: The Influence of Chemical Research on Medicine and Forensic Medicine.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at —J. C. Dollman: Light.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—H. C. Jones: History and Construction of the Fire Engine.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Graduates' Section) (at Cleveland Institution, Middlesbrough), at 7.30.—R. W. Dickinson: Toothed Gearing.

PHILOLOGICAL SOCIETY (at University College), at 8.—Papers on New Liddell and Scott.

PUBLIC LECTURES.

SATURDAY, NOVEMBER 1.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Famous Pharaohs.

MONDAY, NOVEMBER 3.

KING'S COLLEGE, at 5.30.—Prof. E. W. Scripture: The Psychoanalysis the Poet.

GRESHAM COLLEGE, at 6.—Sir Robert Armstrong-Jones: Physic. (Succeeding Lectures on November 4, 6, 7.)

THURSDAY, NOVEMBER 6.

ROYAL SOCIETY OF MEDICINE (1 Wimpole Street, W.), at 3.—Dr. Guisez: Malignant Disease of the Gullet (in French) (Semon Lecture).

FINSBURY TECHNICAL COLLEGE (Leonard Street), at 4.—Julian L. Baker: The Chemist and the Fermentation Industries (Streatfeild Memorial Lecture).

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, at 4.30.—Prof. J. Mellanby: Enzymes. (Succeeding Lectures on November 13, 20, 27.)

FRIDAY, NOVEMBER 7.

KING'S COLLEGE, at 5.30.—Prof. E. W. Hobson: The Ideal Aim of Physical Science.

UNIVERSITY COLLEGE, at 5.30.—R. H. Hooker: The Weather and the Crop. Part II. Economic Effects (Jevons Memorial Lectures). (Succeeding Lectures on November 14, 21, 28.)—At 8.—Prof. G. Dawes Hicks: German Philosophy in the XIXth Century. (Succeeding Lectures on November 14, 21, 28; December 5, 12.)

SATURDAY, NOVEMBER 8.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—E. Lovett: The Amulets of Ancient Egypt and of Modern London.

Science and Philosophy.

THE different branches of knowledge are often classified according to their subject matter. To each is assigned a definite region of experience or a definite group of ideas; the conclusions of those who study these with special application are supposed to be embodied in a series of propositions which convey all that is known on the subject to any one whose interest may be aroused in it. Distinctions drawn on this basis between the various experimental sciences, or between science and mathematics or history, are accepted without question. The physicist gives his material to the chemist to be analysed, asks the mathematician to solve his equations, and inquires of the historian whether his result was known to the ancients; he recognises that these matters lie within their province, not his, and yet he has perfect confidence in their answers. The exact boundaries may sometimes be difficult to draw, and where they occur, disputes may arise between those who approach them from opposite sides; but there are large areas within which all are content to accept the jurisdiction of the recognised occupants.

But with philosophy the position is different. No student of science ever hands over any of his problems to a philosopher, or accepts gratefully from him any help that may be offered spontaneously; and yet the reason for his aloofness does not seem to be merely a diversity of subject matter so complete that the two studies can never enter into contact. For philosophers, who surely know what they are studying, undoubtedly believe that their studies have some bearing upon science; while the bewilderment which philosophic writings produce in most scientific minds is akin to exasperation rather than to indifference. If science and philosophy are distinguished by their subject matter, then either there are problems involving both provinces or there are not. If there are, why do we not work in friendly co-operation? If there are not, why do we quarrel?

In a recent lecture [1] Prof. Graham Kerr suggests that the distinction is one of method, not of matter; and if he is asked why two methods applied to the same matter do not lead to concordant results, he replies that one of them is wrong. We must reject entirely the "old philosophy" and replace it by the "new philosophy—Science." The view is not entirely novel, but it has at least the merits of frankness and directness. It is scarcely a solution of the difficulty. For it cannot be expected to appeal to philosophers; and even those whose sympathies are wholly scientific may be loath to believe that the labours of so many men not obviously

[1] "Science—The New Philosophy," Proc. Roy. Phil. Soc. Glasgow, 52, 187 (1924).

devoid of intelligence have been so entirely futile; it leaves the question why there is a conflict between science and philosophy exactly where it was. But perhaps our chief wonder will be why, if philosophy has hitherto been nothing but error, Prof. Kerr thinks that he exalts the importance of science by calling it philosophy.

The answer is probably to be found in history. Before knowledge was differentiated, and when all serious students were "philosophers," a solution of all the problems of philosophy would have answered all the questions which any of them cared to ask. We suggest that when Prof. Kerr calls science the new philosophy, he means simply that it answers all the questions that he cares to ask. If that is so, nobody will quarrel with him except on a point of mere terminology. But the question remains whether science will answer all the questions (including this one) which other people care to ask. Prof. Kerr recognises himself that there is a diversity of intellectual interest; he complains, for example, that philosophers are indifferent to improvements in observational methods, which interest him so greatly. Is it not possible that he is indifferent to things which interest them, and that in this diversity of interest, which leads to the asking of different questions, lies the true distinction between science and philosophy?

Let us consider from this point of view the problem which causes the fiercest contention, that of the reality of the material world. Science and philosophy are here concerned with the same subject matter, namely, the experience received through the senses. Are they asking the same question about it, or is there confusion arising from their common inheritance of the word "real"? The scientific question is to be answered ultimately by experiment. Now an experiment is simply a portion of experience which is regular in the sense that it can be repeated and can be experienced by all men at all times; improvements in observational methods are improvements or extensions of this regularity. It seems, therefore, that the question which science asks is whether and how far sense-experience can be reduced to or analysed into this kind of regularity. The supreme test of regularity is prediction; and it is easy, therefore, to understand why Prof. Kerr maintains that, to the man of science, the question of reality "was disposed of long ago when it was realised that occurrences in the external world could be prophesied."

Philosophers, however, are not interested in experiment; that is precisely the difference between students of philosophy and science; and therefore this cannot possibly be the question that they are asking. Many of us find it hard to discover what that question is; but it seems to arise from the contemplation of the irregularities of experience. Side by side with the regular portion of sense-experience which an observer shares with all men at all times, and inseparably entangled with it, there is an irregular portion which is peculiar to him at a particular moment and makes it *his* experience. It is almost impossible to frame any question about it in words or to understand a question framed by others for words, being a method of communication between different persons, are necessarily based on the common and regular portion of experience. But if any one can frame such a question, either for himself or for others, and if he finds it interesting, surely it is a legitimate subject of study. It is, however, a study concerning which science cannot possibly have anything to say and on which its conclusions and its success in prediction can have no bearing whatever.

If this view is right, when any one asserts that anything is real he means nothing more and nothing less than that he has been able to satisfy to some extent his intellectual aspirations. When we assert that atoms or electrons are real, we are not deciding between the philosophic doctrines of materialism and idealism because we have no understanding of those doctrines or interest in them. When also a philosopher asserts that time or space is not real, he is not throwing any doubt on any scientific doctrine; for the purpose of that doctrine, namely, to describe and explain the regularities of sense-experience, does not appeal to him. While this mutual lack of interest continues—and it is something very fundamental in the constitution of human minds—there can be no reconciliation between science and philosophy. For knowledge is what somebody thinks; science is what men of science think about, philosophy what philosophers think about; and while they continue to think about different things and ask different questions, no idea that is important to one can be important to the other.

Reality was not, however, the only problem of the "old philosophy" from which modern science and philosophy descend. Science, we agree, must solve this problem for its students; but can it solve the other problems, such as the nature of justice or of beauty? Prof. Kerr apparently thinks it can. The New Philosophy, he tells us, identifies greater human perfection with greater prosperity and happiness. But there are others, not less entitled to speak for science, who cannot accept the ideal of the contented pig, and would regard wisdom and virtue as no less important ingredients of perfection. When science speaks with divided voices, who shall decide? Philosophy, of course, say the philosophers; and our difference with them in the matter of reality need not make us unwilling to grant their claim. For if, as has been suggested, the philo-

ophic view of reality is based on the consideration of individual and irregular experiences, concerning which no two persons can agree and which are important for that very reason, surely it may throw some light on moral and æsthetic judgments, concerning which opinion is similarly diverse. If philosophy takes for her province those subjects round which, from their very nature, bitter disputes must ever range, we may be well content to leave her in possession and to share with mathematics and history the province of positive knowledge. Nor will she have reason to complain if we reject any conclusions that she may offer us; for our rejection will merely extend her sphere and offer her new fields to conquer. N. R. C.

Primitive Fishes and Petroleum.

(1) *The Evolution and Distribution of Fishes.* By Prof. John Muirhead Macfarlane. Pp. ix+564. 25*s.* net.
(2) *Fishes: the Source of Petroleum.* By Prof. John Muirhead Macfarlane. Pp. ix+451. 25*s.* net.
(New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1923.)

(1) THESE two very interesting books by the professor emeritus of botany in the University of Pennsylvania form an aftermath of his early studies of the fossils of the neighbourhood of Edinburgh. In his previous volume, "The Causes and Course of Organic Evolution," he propounded the thesis that "organisms evolved first in fresh-water areas, and only by degrees spread into marine surroundings," and the first and larger of the two volumes now under review deals with the application of this view to the fishes. The volume, the preparation of which must clearly have involved a vast amount of research into the literature of the subject, makes out a strong case for the author's view, and in spite of its multiplicity of detail, provides interesting reading for any one interested in the evolutionary history of the lower vertebrates.

It is to be regretted that the author will be regarded by most vertebrate morphologists as having to a certain extent queered his pitch by his adhesion to certain theories now generally discarded. He is a firm believer that vertebrates are descended from nemerteans. The majority of morphologists are probably now in agreement that the various types of ancestral vertebrate above the cœlenterate level of organisation have continued on their evolutionary way and are no longer to be recognised as persisting in any of the invertebrate groups of to-day, whether Nemertea, Annelida, Arthropoda, or any other.

From his various references to the air-bladder, it would appear that the author regards this organ as being in the teleostean fishes respiratory in function, and that he believes that in marine fishes it tends to degenerate in correlation with the higher degree of oxygenation of the water making the gills more competent to deal with the respiratory needs. As a matter of fact, our present-day knowledge of the morphology and physiology of the air-bladder seems to establish clearly (1) that this organ of the teleost is an evolutionary development from the lung, (2) that its function is a hydrostatic one—serving to keep the specific gravity of the fish equal to that of the water in which it swims, regardless of changes of pressure due to changes of depth, and (3) that its disappearance in particular teleosts is, as a general rule, related to their having adopted a bottom-frequenting habit.

Passing over such points of detail, which after all are not essential to the main thesis, we find that the larger part of the book is devoted to a discussion of the physical and biological environment of fishes during the various geological periods (Chapters iv.-viii.), and to a survey of the distribution of the various groups of fishes in relation to time and space (Chapters ix.-xiii.). The chapters dealing with these subjects are preceded by three introductory chapters—the first more or less philosophical, the second dealing with geological conditions in relation to the evolution of fishes, and the third dealing with the evolution of fishes from the invertebrata. The closing chapters of the book deal with the distribution of fishes in relation to geological and geographical conditions in the past (Chapter xiv.), fishes in relation to a Southern continent (Chapter xv.), the problem of Lake Tanganyika (Chapter xvi.), and the geographical and geological relations of the more primitive fishes (Chapter xvii.).

As has already been indicated, the main sections of the book are palæontological, and these gain much in interest and value from the author's breadth of view. He appreciates the disintegrative effect of bacterial and other agencies, and sees that to explain the wonderfully complete and exquisitely preserved entire fish skeletons occurring in certain deposits, it is necessary to assume abnormal conditions such as showers of volcanic ash at the time of their entombment. He also would appear to appreciate—as so many palæontologists do not—the need of taking due account of everything available from the studies of embryologists and anatomists upon allied types of existing animals when endeavouring to draw general morphological conclusions from the facts of palæontology.

In his review of the successive geological formations, the author urges that the Downtonian and other Upper Silurian deposits, containing abundant remains of primitive fish, are undoubtedly of fresh-water origin. He accepts the generally admitted fresh-water character of the Old Red with its archaic types of elasmobranchs,

dipneusts, and ganoids. During the earlier part of the Carboniferous period the abundant fish population was still predominatingly fresh-water, although now for the first time seaward migration of various elasmobranchs foreshadowed the marine fish fauna of the Carboniferous Limestone. These marine fishes soon died out, and in Triassic times the predominatingly ganoid fish fauna became again restricted to fresh water. In Jurassic times, fish began again to spread into the sea—the immigrants this time including actinopterygian teleostomes as well as elasmobranchs. This invasion of the sea by elasmobranchs from fresh water became still more pronounced during the Cretaceous period, a number of genera becoming conspicuous that still persist at the present day, while they were now accompanied by typically teleostean derivatives of the Ganoidei. In the fresh waters were other teleostean types, ancestors of some of the great fresh-water groups of to-day, while with them were still abundant dipneusts and ganoids. Curiously, the Cretaceous teleosts all died out and became replaced by new Eocene types, although many of the elasmobranchs persisted unchanged.

(2) The second volume, like the first, is written to sustain a particular thesis, in this case more restricted in scope but at the same time of greater practical interest. While there is general agreement that mineral oil is of organic origin, there is no such general agreement as to the type of organisms to which the great oil deposits owe their origin, some assigning the chief rôle to vegetable organisms, others to Protozoa such as Foraminifera, others again to fish. Prof. Macfarlane is a strong supporter of the last-mentioned view, and in this volume he marshals the evidence in what will seem to many convincing fashion, in spite of his various heresies in regard to the evolution of the early vertebrates.

The author points out the frequent association in geological time of oil-containing deposits with rocks containing abundant remains of fresh-water fish. Although a botanist, he does not allow that vegetable remains have played any appreciable part in the production of oil. "The group of fishes alone in the animal kingdom conforms in every respect to the requirements for formation of crude petroleum." Their sudden destruction in immense shoals, their frequent richness in oil, their tendency to float and to accumulate in masses, and the rapid disengagement of oil from their decaying bodies, present a combination of factors favourable to the production of petroleum "not even approached distantly by any other group of animals." Kerogenite or oil-shale—the main source of crude petroleum—is invariably associated with fish remains, and in accounting for its formation the author recalls the experimental work of Stuart, showing how oil in muddy water tends to be carried down and entangled among the deposits of mud at the bottom.

Prof. Macfarlane recognises in the course of geologic history a number of distinct epochs during which oil formation was particularly active—an Old Red epoch synchronous with the abundance of fresh-water elasmobranchs, dipneusts, and other primitive fish during the Middle and Later Devonian period, a Jurassic epoch when the abundance of fresh-water ganoids reached its climax, a late Cretaceous and early Tertiary epoch marked by great abundance of marine elasmobranchs and still later epochs marked by oil-deposits of teleostean origin—first marine and later, as the present day is approached, fresh-water.

The author takes an optimistic view as to the oil supplies of the future. In addition to large, as yet untapped, supplies of free oil in various parts of the world, he emphasises the presence of vast expanses of oil-shale, both in the old and new worlds, which merely await the development of more efficient means of extraction. Holding the views he does, he very rightly insists upon the need of highly trained geologists, with special training in fish palæontology, for the working out of possible sources of oil-supply in the future.

Properties of Colloidal Systems.

Licht und Farbe in Kolloiden: eine phänomenologische Monographie. Von Prof. Dr. Wolfgang Ostwald. Erster Teil: Optische Heterogenität, Polarisation, Drehung, allgemeine Absorption, Heterogenitätsfarben, Brechung. (Die Ergebnisse bis 1914.) (Handbuch der Kolloidwissenschaft in Einzeldarstellungen, Band 1.) Pp. xiv + 556 + 17 Tafeln. (Dresden und Leipzig: Theodor Steinkopff, 1924.) 7.60 dollars.

THE large volume before us is the first part of a work designed to deal exclusively and exhaustively with the optical properties of disperse systems. Readers familiar with the existing text-books of colloid chemistry, in which a score of pages, or less, is devoted to these properties, will be struck with the large amount of information which the author has made readily accessible. The method of presentation he has chosen is, we are told, the "phenomenological," an adjective which the author feels obliged to explain even to the German reader; he does so in the following terms: "The author sees the characteristic of this method of presentation in the attention paid to *all* phenomena, and not only to selected ones, which fit a particular theory. A second characteristic consists in the attempt to separate concepts and to arrange phenomena in orderly fashion as neatly as possible." It will be

nerally agreed that these are desiderata in all scientific iting, but the author develops an antithesis between henomenological and mathematical treatment which ill scarcely command such general assent. Fortunately, the important question whether quantitative lations can be discovered, or be proved to hold generly, by methods other than mathematical, need not be bated here, as the vast majority of the phenomena eated in the work under review are much too comicated for mathematical treatment at present. Even here such treatment has been carried out, with all the paratus of modern mathematical physics, as in the se of gold sols, the results are only in moderate agreeent with experimental measurements.

The six headings of the sub-title give an indication the scope of the present volume. Optical heterogeneity and its most striking macroscopic manifestation, rbidity, are first discussed generally, and the contriutory factors; reflection, refraction and scattering the interface are analysed. The Tyndall phenomenon is then treated at great length; Rayleigh's rmula for non-conducting particles and Mie's for gold articles, both small compared with wave-length, are iven and calculated results are compared with exerimental determinations. A chapter on the design nd use of the ultra-microscope follows, which far xceeds in scope and completeness anything to be ound in the existing literature. It is illustrated with number of exceptionally beautiful plates, several of hem in colour, which will give the reader unfamiliar ith the instrument some idea of the appearance of ltra-microscopic images and, incidentally, of the ifficulty of interpreting most of them.

The chapter on polarisation falls into two main ivisions: the state of polarisation of the light reflected nd scattered by small particles, and the optical activity f certain sols. Among the most interesting phenonena described is the multirotation of gelatin, the hange of specific rotation with age being paralleled by change in viscosity. The connexion between the wo is obscure, and its elucidation might throw light n the constitution of emulsoid sols. The chapter on bsorption deals largely with the applicability of Lambert's and Beer's formulæ to disperse systems, and the effect of the degree of dispersity on selective absorption. Colours produced by optical heterogeneity form the subject of the next section; as one of the chief factors in producing colour in systems with *non*-metallic particles is the preferential scattering of the shorter wave-lengths, there is a certain amount of overlapping with the first section. In the final chapter the problem of a "mean" refractive index of heterogeneous systems and attempts to deduce it from the constants and the volume ratios of the phases are treated.

The author confesses to a special affection for his present subject, and his enjoyment in developing it is, indeed, quite obvious. While such enjoyment on the author's part is certainly stimulating to the reader, it has led to a breadth of treatment which (as the preface admits) may sometimes seem excessive, and to a certain amount of repetition. The latter may not be a defect to the student, who will not read the book at one sitting nor probably "with his feet on the fender." The author naturally has to deal with a number of controversial subjects—the interpretation of the microscopic and ultra-microscopic images of gels is a good example—and, while he does so with plenty of spirit, he manages to write entirely *sine ira et studio*.

The book, as stated on the title page, covers the literature up to 1914. Even during the comparatively sterile period of the last ten years some investigations of fundamental importance have appeared, *e.g.*, to mention one only, that by Porter and Keene on sulphur suspensions containing particles *large compared with wave-lengths* and indigo in *transmitted* light. No theory of this phenomenon is available so far; until one is found there will be a distinct gap in the optics of disperse systems.

This and a few other omissions caused by the avowed limitation to work done before 1914 do not in any way detract from the value of the book. It provides a very large amount of information, little of which is to be found in the existing text-books, on some of the most immediately striking, and at the same time important, properties of colloidal systems. The purchaser will have to let this consideration weigh against the price, which, like that of many recent German books, is very high—although no doubt the lavish and expensive illustrations go some way towards justifying it.

E. H.

The Appeal of the Himalaya.

Wonders of the Himalaya. By Sir Francis Younghusband. Pp. vii+210. (London: John Murray, 1924.) 10*s.* 6*d.* net.

SIR FRANCIS YOUNGHUSBAND is one of the great Asiatic explorers, for he was almost the first to cross Central Asia from Pekin to India, the first to traverse the Mustagh and other high passes in the north-western Himalaya, and was in later years head of the British expedition to Lhasa. The effect of his new book should be to inspire many of the coming generation with his passion for exploration, and especially for investigation of the unsolved problems of the Himalaya. The volume is a popular narrative of four of his early journeys, made when he was a

T I

subaltern in the King's Dragoon Guards. Life in that regiment did not satisfy him.

"I would gladly," he says, "have entered into the life of a cavalry regiment if the regiment had been really in earnest about training itself for war. But they were not. The Colonel had had me up in orderly room and told me that I was always going on as if we were preparing for active service; but we never went on active service, so it was of no use preparing for it. What we had to do was to prepare to turn out smart for parade when some general came round, and in that way we should get a good name."

Lieut. Younghusband came of a family of explorers. He was a nephew of Shaw of Yarkand, and a regiment governed by a man who would have been appropriately its head tailor gave inadequate scope for his energies. He soon made his name as a most capable explorer and was sent on various missions, his success in which gained for him, by the age of twenty-four, the Gold Medal of the Royal Geographical Society. The author expresses the hope that his book will be read by boys; but it would appeal to readers of almost any age, owing to its expression of the author's deep enjoyment of his experiences, his appreciation of the good qualities of his men, and its graphic descriptions of Himalayan geography. The expeditions described include his preparatory traverse in the southern Himalaya through Dharmsala to Simla; to Manchuria in 1886; across Central Asia from Pekin to Rawal Pindi, during which he passed through the Karakorams and over the Mustagh Pass; and a special mission in northern Kashmir to search for the supposed Saltoro Pass, to investigate the depredations by Hunza raiders in the Pamir and Hunza country, and to note the proceedings of a Russian expedition that was secretly visiting that region.

Sir Francis Younghusband is a dauntless traveller, and his courage is displayed by his defiance of those who regard beginning a sentence with a preposition as one of the worst of literary sins. He does it habitually—half-a-dozen times on a page, and with two succeeding sentences beginning with "but."

The narratives are throughout of intense interest, and may be read with pleasure by those who know the previously published accounts of the expeditions, for amid the stories of narrow escapes from avalanche or suspicious Asiatics are pæans on the Himalaya and their wonders and majesty. Sir Francis Younghusband describes their barrenness, poverty, and intertribal strife; but he makes his reader share his feeling that these ills are evanescent, and that the grandeur, purity, and light of snow-capped mountains are the source of their never-tiring joy and inspiration.

Mathematics for Engineers.

(1) *The Design of Diagrams for Engineering Formul and the Theory of Nomography.* By Dr. Lauren I. Hewes and Herbert L. Seward. Pp. xiii + 11 (London: McGraw-Hill Publishing Co., Ltd., 1923 25*s*.

(2) *Elements of Graphic Statics.* By Prof. Clarenc W. Hudson and Prof. Edward J. Squire. Pp. viii + 9 (London: McGraw-Hill Publishing Co., Ltd., 1923 6*s*. 3*d*.

(3) *A Treatise on Engine Balance using Exponential* By P. Cormac. Pp. xi + 151. (London: Chapma and Hall, Ltd., 1923.) 21*s*. net.

(4) *Leçons de mécanique rationnelle, professées à l'Éco des Mines et de Métallurgie Faculté technique d Hainaut à Mons.* Par François Bouny. Tome 1 Calcul vectoriel, Cinématique, Statique, Potentie Pp. viii + 600. (Paris: Albert Blanchard; Mons Librairie Leich, 1924.) 50 francs.

(1) MESSRS. Hewes and Seward's account o chart construction for engineering formul consists of two main sections. The first 34 page are somewhat general in character, and explain th formation of functional scales and the drawing o charts in general. The remaining 70 pages are devote to the theory and practice of nomography. Bot portions are well written, with a wealth of excellen diagrammatic illustration. The book is well printe and the charts well reproduced.

The volume is obviously intended for readers wh are not shy of mathematical reasoning and calculation This is illustrated by the beginning of Chapter iii. where the nomography proper commences. The authors base themselves on the fundamental property of collinear points, namely, that their Cartesian co-ordinates satisfy a determinantal equation, and they show how various types of problems can be solved nomographically. If it can be assumed that engineers can follow such reasoning with ease, then there is something to be said in favour of this mode of presentation; and the authors do it fairly well. We must point out, however, that it is fatal to become a slave to one particular line of reasoning or to one particular method. To do all formulæ by the determinantal method is dull and by no means educative, while often this method is distinctly more laborious than straightforward practical processes which can be readily devised in most cases from easy first principles. Probably most engineers would prefer elegance and ease of design to logical completeness of mathematical argument.

(2) In their little book on graphic statics, Profs. Hudson and Squire give a careful study of the

theory of forces in a plane, and then apply the methods to simple structures, and to the discussion of shearing forces and bending moments. The book is pleasant to read, never irrelevant and always to the point. Fig. 9a is upside down!

(3) The first few pages of Mr. Cormac's book tend to discourage the prospective reader. One does not like such disregard of usual practice as $a \times -1 \times -1 = a$. One cannot approve of the statement that $dz/d\theta = \iota z$ gives $z = e^{\iota\theta} + C$, so that if $z = 1$ when $\theta = 0$, we get $C = 0$. It is unpleasant to see $\lfloor 3$ written $\lfloor_3$. It is unusual to write $(1 + 2h \cos\theta + h^2)$ with (1 on one line and the remainder in the next. But all this only means that Mr. Cormac should have submitted his manuscript or the proofs to a severer scrutiny: it does not destroy the interest and value of the attempt made by the author to develop the theory of engine balance by means of exponentials, or more correctly by the use of vectors in the Argand plane. The idea is that a mass m at distance r from an axis of rotation ω, in direction θ measured from a fixed direction, has acceleration representable by $-r\omega^2 e^{\iota\theta}$ and an "inertia resistance" representable by $mr\omega^2 e^{\iota\theta}$. In conjunction with various expansions like $(1 - r\cos\theta)/(1 - 2r\cos\theta + r^2)$ in terms of Fourier series, elaborately worked out in an appendix of 20 pages, this notation is applied to various types of engines, flywheels, and cranks. The book is an interesting application of complex numbers and de Moivre's theorem to an important topic in engineering practice, and is on the whole well written.

(4) Prof. Bouny's book is the first part of a treatise on the principles of mechanics intended for students of technology. The present volume discusses vectors, kinematics, and statics (including potential theory). Volume II. will deal with particle and rigid dynamics and with the mechanics of continua. It is stated that the book represents lectures delivered to first and second year students at the School of Mining and Metallurgy at Mons, the students being in general beginners in the study of theoretical mechanics.

As is to be expected, the book is very reminiscent of French treatises, both in matter and in method. It is in fact a treatise in the real sense of the word, the subject being discussed with the logical completeness and the logical sequence that form so admirable a feature of French school and university text-books. In Great Britain, text-books are written with the object of coaxing the student, especially if he happens to be studying technology, so that he is suspected of taking but little interest in theoretical and fundamental principles. French and Belgian writers do not coax their readers. They explain their subject carefully, logically, and with full-dress seriousness. Examples, if they exist at all, do not pander to the tastes of engineers who like to see practical applications with numerical results!

The present volume is in fact one that anybody may read who wishes to study the principles of mechanics for their own sake, and not merely if he happens to be interested in mines but is yet prepared to admit that theoretical principles also deserve attention. The standard is somewhat high. Only the best equipped mathematicians among technological students at British universities could read with profit Prof. Bouny's book. Mathematicians should certainly read it. There are nearly 300 examples with solutions.

Vectorial notation and methods are used throughout. For the mining engineer and metallurgist this must be a distinct hardship, because the kind of mechanics they need is such that the use of vectors would be sheer faddism. This is tacitly admitted by the author himself, who gives the most important results in ordinary Cartesian, polar, or intrinsic notation as the case may require for practical application, after having deduced the vectorial forms. S. BRODETSKY.

Practical Human Physiology.

Human Physiology: a Practical Course. By C. G. Douglas and J. G. Priestley. Pp. ix + 232. (Oxford: At the Clarendon Press; London: Oxford University Press, 1924.) 12*s.* 6*d.* net.

DURING the last twenty or thirty years, with the vast increase in physiological knowledge, especially from animal experiments and from the chemical point of view, there has been unfortunately an increasing divorce between medicine and physiology to the detriment of both. The researches of Haldane and his fellow-workers on respiration have been mainly human experiments, and probably most of his results could not have been carried out in any other way. This is the point of view of the book before us, and the experiments given can all be performed on the students themselves. It is based on the practical course for the honour school of physiology at Oxford, and taken with Sir Charles Sherrington's book on "Mammalian Physiology" the ground is covered very thoroughly. Naturally, a large proportion of the book is devoted to respiration—nearly three-quarters, using respiration in its widest sense of the transport of oxygen and carbon dioxide by the blood as well as through the lungs. This section includes such important subjects as the effects of muscular work and the administration of oxygen, the determination of the basal metabolism, of the volume and reaction of the blood as well as the more usual determination of oxygen and carbon dioxide carrying capacity. The book does not,

however, deal with respiration alone. Modern methods of blood examination are discussed, including the agglutination of the red cells, blood grouping, transfusion and the fragility of the red cells. The functions of the kidney are investigated, water diuresis is discussed, and methods given for the determination of the sugar and urea in the blood. The recent important work of J. B. S. Haldane on the maximum concentration of chloride and bicarbonate in the urine is very suitable for class work and is included.

Under the heart and circulatory system, blood pressure and the polygraph tracings of the pulse are investigated experimentally, and the electro-cardiograph is shortly referred to. Finally, there is an excellent section on the investigation of the stomach and intestine by X-rays and the stomach tube. Contrary to general impressions, these facts are very suitable for class experiments, and easily rouse interest and give valuable results.

A practical course serves two main purposes — to demonstrate the general truth of the science and to train the student in methods of investigation. For the man who devotes his life to physiology, all methods are almost equally important, and animal experiments here may have advantages over experiments on man, as well as some disadvantages. Most students of physiology intend to practise medicine, and here perforce the subject of experiment is generally human, whether in the great experiment designed by Nature such as disease, or in careful observation of treatment. It is in this way that the present book is particularly valuable.

In one other way the volume is admirable. Many practical books consist of a list of unconnected experiments, and the book is of little use outside the laboratory. This book is eminently readable, and the experiments are put together as a connected whole, although complete details are given for the actual experiments and for the calculation of the results—an important thing in any respiration work.

The only serious drawbacks are the large branches of physiology which are left untouched—the central nervous system and metabolism as studied by changes in the urine with work, rest, and various diets. Perhaps the authors are right in leaving this to be written by some one else, and keeping themselves to the branches in which they have such unrivalled practical experience.

The course is more suitable for small advanced classes. Perhaps in a few years, when other courses similar to this and covering the other branches of physiology have been written, it will be possible to abstract a shorter and simpler practical course of human physiology which should be followed by all students of medicine.

Our Bookshelf.

Birds in their Relations to Man: a Manual of Economic Ornithology for the United States and Canada. By Dr. Clarence M. Weed and Dr. Ned Dearborn. Third edition, revised. Pp. viii+414+18 plates. (Philadelphia and London: J. B. Lippincott Co., 1924.) 15*s.* net.

As this book deals with North American birds and conditions, its interest to readers in Great Britain is naturally general rather than particular. Nearly half the space is allotted to a detailed consideration of the food habits of the species which are of most importance economically in the United States: in addition, however, there are chapters on methods for studying the food of birds, on the development of economic ornithology in America, on birds' food in general, and on measures for the conservation and encouragement of useful species and for preventing the depredations of those which are injurious.

From among the many examples to be found in the book, the following evidence as to the economic value of birds may be cited. During a plague of canker-worms in Illinois orchards, the stomach contents of 141 birds belonging to 36 species were examined. Canker-worms were found in 60 per cent. of the individuals and 72 per cent. of the species, and formed 35 per cent. of the total food of all the birds examined. It may be noted also that, so long ago as 1885, economic ornithology was taken up by the Federal Government, and the task of investigation and public instruction entrusted to what is now the Bureau of Biological Survey of the U.S. Department of Agriculture.

A summary is given of the State and Federal (but not Canadian) laws for the protection of birds, and the underlying principles of these are of some interest. The State laws, varying in detail from one State to another, are of primary importance and are based on the assumption that all game and wild birds are the property of the State, and may only be killed as the State Government may permit: landowners have no privileged position in this respect. The Federal law before 1913 merely reinforced the local laws in incidental ways, but it was then decreed that birds which do not permanently remain within a given State are the property of the United States Government, and so certain migratory species are now protected by a Federal Act. The authors fail to carry this development a stage further and to mention the Migratory Birds Convention of 1917, which provided for reciprocal legislation in Canada and the United States. One also notes that the bibliography contains no reference of later date than 1915.

Précis de chimie physique. Par H. Vigneron. Pp. xii+408. (Paris: Masson et Cie, 1924.) 30 francs.

M. VIGNERON'S book deals with general theories rather than with details of experimental methods, and he is therefore able to cover a wide range of topics in a somewhat small space. He points out that a large part of the subject can be discussed adequately from the kinetic point of view by means of molecular models; but that after a certain point has been passed, these have to be elaborated more and more, until they become of no real value in the quantitative interpretation

the phenomena. It is at this point that thermodynamical relations become important, since the mechanism of the processes can then be neglected; but with the obvious drawback that these relations throw very little light on the mechanism, and are therefore more satisfying to the physicist than to the chemist.

It is, indeed, not unusual in France for physical chemistry to be studied and taught by a physicist, instead of by chemists only, and this difference may account for a rather refreshing variation in the author's method of treatment; but this is counterbalanced by his complete lack of interest in the chemical characteristics of the materials studied. Thus all his phase-rule diagrams are anonymous, and in this way lose the interest that comes from studying facts instead of theories; and he attributed to cyanobenzene, "another organic compound," as he explains to his readers, an unsymmetric quality which this simple and symmetrical substance could not possibly possess, and was actually detected in the case of amyl *p*-cyanobenzylideneaminocinnamate. Such an error would be impossible in the case of a chemist with even a modest knowledge of organic chemistry.

This view of the author's own limitations is confirmed by the fact that the chapter on physical properties and chemical constitution contains no reference to optical activity, by his classification of the fats as "glucosides" of the fatty acids, and by his statement that oleic can be converted into stearic acid by "adding to its molecule an atom of hydrogen." The book may, however, be heartily commended to chemical students who have already mastered this side of their subject, since they can be quite sure that there will be no duplication, and that they will find the author's method of treatment both novel and stimulating.

Chemistry for Dental Students. By Prof. H. Carlton Smith and Rachel M. Smith. Fourth edition, revised and enlarged. Vol. 1: *Qualitative Analysis and Dental Metallurgy.* Pp. vii+186. 12*s.* 6*d.* net. Vol. 2: *Organic and Physiological Dental Chemistry.* Pp. v+320. 17*s.* 6*d.* net. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1923.)

THESE volumes, comprising the fourth edition, are intended to provide for courses in chemistry, dental metallurgy, dental materia medica and physiological chemistry for dental students, and have been written primarily to meet the requirements of American students. Nevertheless the methods adopted are sufficiently general to appeal to wider interests. The sections on microchemical analysis and physiological chemistry are to be noted specially, particularly Chap. xviii. on saliva. The subject matter for these sections has been selected with special reference to dental problems, and is quite likely, from the method adopted, to stimulate a desire on the part of the student to learn more of the subject generally. The chapter on tooth decay, being a readable summary of the present state of knowledge of the subject, may be recommended to others besides dental students.

The plates are good and give an adequate idea of the appearance of the substances as seen in the microscope. References are given to original work and to special text-books, mostly to American works. It would be an advantage to British students if references to corresponding British text-books and original work were furnished.

The authors' intention appears to be to induce students to continue their study of dental chemistry, and in this they may fairly claim to have been successful.

J. J. F.

Collective Index of the Journal of the Institute of Brewing, 1911 to 1923. Compiled by W. H. Bird. Pp. iv+330. (London: Harrison and Sons, Ltd., 1924.) n.p.

THE production of indexes is a laborious and often a thankless task, yet to their compilers the scientific world owes a deep debt of gratitude. The work before us is carried out consistently upon a recognised principle, and is presented in a clear and workmanlike manner. In adopting the principle of the "Inverted Title" as the basis for the construction of his Index of Subjects, Mr. Bird is probably following the style of an earlier index to the Journal of the Institute. Our criticism, at any rate, is directed to show the defects of indexes prepared on this principle. Such indexes are, of course, in reality "Title Indexes"; they serve as subject indexes only by the accident of the language of their titles. As the following illustration will show, such indexes are cumbersome, owing to the repetition of the titles, inconvenient for study, and costly to produce. For example, "Cold: beer towards—, and the Wallerstein process; sensitiveness of. P. Petit. 1916. 468." This entry, suitably modified, appears four times in the Index—occupying eight lines. In the modern type of index one entry would suffice, with a reference from the Wallerstein Process. Moreover, the modern index would bring together matter which in the above Index is distributed under "Chilling," "Cooling," "Refrigeration," "Temperature," etc. The "Inverted Title" index still survives in the book trade, but it has long been discarded from library practice. It is, in our opinion, wholly unsuited for the purposes of Collective Indexes to the papers of learned societies.

E. W. H.

Infection and Resistance: an Exposition of the Biological Phenomena underlying the Occurrence of Infection and the Recovery of the Animal Body from Infectious Disease; with a Consideration of the Principles underlying Specific Diagnosis and Therapeutic Measures. By Prof. Hans Zinsser. Third edition. Pp. xvi+666. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1923). 24*s.* net.

PERHAPS no medical or biological subject has expanded to such an extent as that of immunity, when one remembers that its origin dates back only to the late 'eighties of last century. Its doctrines have, however, revolutionised the medical outlook on the questions of infection and resistance and are now bearing practical fruit in the prophylaxis and treatment of infective disease. It is scarcely possible for one man unaided to deal adequately with the whole subject. All that he can do is by extensive and intensive study to give a critical estimate of the general trend and scope of the subject. This, Dr.

Hans Zinsser, professor of bacteriology and immunity at Harvard, has attempted to do, and, in our judgment, with a great measure of success. We have carefully read through his book and can strongly recommend it as an authoritative work. On every page are the signs of extensive acquaintance with the literature, and from all the wealth of details and contradictions of the latter, he has succeeded in creating a readable account of what must prove a fascinating subject of study to all. W. B.

Continuous Current Circuits and Machinery. By Prof. J. H. Morecroft and Prof. F. W. Hehre. Vol. 1. Pp. viii+467. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1923.) 20*s*. net.

THIS book is designed primarily for the use of students in engineering schools. An elementary knowledge of physics and mathematics is all that is demanded of the reader, and yet a good introduction is given to practical engineering calculations and methods. The authors begin by a brief description of the electron theory, as many of the phenomena described follow readily when this theory is adopted. Some of the sentences, however, may well puzzle the beginner. "This shortage of electrons at the end of the rod constitutes the positive charge at this end." The positive charge, therefore, seems to have no real existence. Similarly we are told that a negative charge can exist in a perfect vacuum. It, also, can have little real existence. This is better, however, than talking about positive and negative fluids.

Following a prevalent practice among engineers, the authors seem to make little distinction between magnetic induction and magnetic force. A *gauss* is defined as a *maxwell* per square centimetre. It is better to define the maxwell as the unit line or tube of magnetic induction and not as a line of force. Many useful examples in electrical engineering are given, and the student who works through them all will have made good progress in becoming a qualified electrical engineer. We regard this as a book suitable for first and second year students at a technical college and can recommend it as such.

A Bibliography of Sir Thomas Browne, Kt., M.D. By Geoffrey Keynes. Pp. xii+255+5 plates. (Cambridge: At the University Press, 1924.) 42*s*. net.

THIS handsome volume, of which only five hundred copies have been issued, is dedicated to the memory of Sir William Osler, who was one of the most enthusiastic admirers of Sir Thomas Browne. The work consists of twelve sections, the first ten of which are devoted to the bibliography of Sir Thomas Browne's writings, and the last two to the bibliography of biography and criticism and the sale catalogue of Sir Thomas Browne's library, all but two of the sections being preceded by a bibliographical preface. There are four appendices containing the bibliographies of imitators of "Religio Medici" and "Vulgar Errors," and of the works of Dr. Edward Browne, Sir Thomas's eldest son, and an account of Simon Wilkin, the Norwich publisher and editor of Sir Thomas Browne's works. The text is interspersed with reproductions of the MS. and title pages of early copies of "Religio Medici," "Hydrotaphia," "Christian Morals," and other works. There are two fine portraits, the first, which serves as a frontispiece, being that of Sir Thomas and his wife, Dame Dorothy Browne, by an unknown artist, and the other that of Simon Wilkin.

Mr. Geoffrey Keynes, who is attached to the surgical unit of St. Bartholomew's Hospital, is to be congratulated on his scholarly achievement, on which, as we learn from the preface, he has been engaged for sixteen years. It will rank next to Wilkin's classical edition as the most important contribution to the literature of Sir Thomas Browne's works.

History of the Great War: Based on Official Documents. Medical Services General History. Vol. 4: *Medical Services during the Operations on the Gallipoli Peninsula; in Macedonia; in Mesopotamia and North-West Persia; in East Africa; in the Aden Protectorate, and in North Russia. Ambulance Transport during the War.* By Maj.-Gen. Sir W. G. Macpherson and Maj. T. J. Mitchell. Pp. xvi+711. (London: H.M. Stationery Office, 1924.) 25*s*. net.

THIS is the final volume of the general history of the Medical Services during the War, and is perhaps the most readable. The ground covered is adequately expressed in the title. The book shows the great and varied difficulties which had to be contended with, and while it is clear that towards the end of the campaigns the problems were mastered to a certain extent, there were deplorable breakdowns in the Dardanelles, Mesopotamia, and East Africa, some being so notorious as to lead to Parliamentary inquiries. These disasters are attributed mostly to lack of preparation before the campaigns started, but the editors, naturally perhaps, do not commit themselves to an exact statement as to the rank and position of those actually concerned. They admit, however, that "in some respects the administration of the Medical Services was a factor in the breakdowns."

Introduction to Modern Philosophy. By C. E. M. Joad. (The World's Manuals.) Pp. 112+4 plates. (London: Oxford University Press, 1924.) 2*s*. 6*d*. net.

MR. JOAD'S little volume is clearly written and gives a short outline of the present tendencies in modern philosophic thought. It contains chapters on the difference between idealism and realism, Mr. Bertrand Russell, Croce and Gentile, pragmatism, and finally Bergson. At the end of each chapter is a criticism of each system. The work is rather too short to be of much use to scholars, but it ought to fulfil admirably the purpose for which it is written, namely, to present to non-professional readers the works of the professional writers.

Physikalische Chemie der Zelle und der Gewebe. Von Prof. Dr. Rudolf Höber. Fünfte, neubearbeitete Auflage. Hälfte 2. Pp. v+545-906+xi-xvi. (Leipzig: Wilhelm Engelmann, 1924.) 12 gold marks.

THE second half of this volume, of which the preceding part was noticed in these columns on July 21, 1923 (vol. 112, p. 93), has been received. It contains the remaining Chapters viii. to xii. of the new edition.

Letters to the Editor.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

Wind and Waves.

In a letter published in NATURE on August 19, 1920, p. 777, I said that, judging from appearances, wind-formed waves increased in length only when the waves were in a "breaking" condition, and it was suggested that the breaking crests, by imparting their momentum to the upper strata of the water, and so establishing a gradually increasing surface current, would necessarily also cause a gradual increase in the wave-length equal to the increase of stream speed per wave-length × by the period of the wave. An example of the alteration in the lengths of a train of breaking waves may be seen at the foot of any weir where the flow is sufficient to form a stationary "bore." The wave where the stream over the apron is first arrested carries a large breaking crest, and down-stream follow several waves also breaking, but not so heavily. Following these again are waves which do not break, and counting from the first wave, observation will show that the distance from crest to crest diminishes notably so long as the waves are breaking.

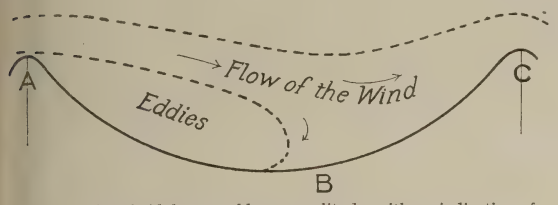

FIG. 1.—Trochoidal wave of large amplitude, with an indication of the direction of the flow of the wind.

The cause indicated in my earlier letter must certainly have some effect, but it seems inadequate to account for the long waves met with in the ocean. Another way in which the action of the wind may increase the wave-length is that when the wave slopes are steep, each crest acts as a screen to the water surface immediately to leeward, and the full force of the wind operates only on the windward slopes, while the trough and lee surfaces are more or less becalmed (Fig. 1). The results of this irregular distribution of wind pressure are considered briefly in the present note.

There have been no accurate observations of the shapes of wind-formed waves—not sufficiently accurate, that is, to distinguish them either from the trochoidal waves of Rankin and Froude or irrotational gravity waves, which have been only partially investigated. So long as the amplitude is small all these forms should be nearly identical, but the limiting form for the trochoidal wave is a cycloid, the crest of which is a knife edge with an angle of 0°, while for the irrotational wave the limiting crest angle (according to Stokes) is 120°.

The other chief difference between these forms is that while in the trochoidal wave each particle moves in a circular orbit, and returns to exactly the same position after each wave period, in the irrotational wave there is a continuous forward motion of the fluid, greatest at the surface and rapidly decreasing with the depth, but always small compared with the wave speed. Thus, in the irrotational wave, the orbits of the particles are not closed curves but form a succession of loops.

It will be sufficient for the present purpose to consider only trochoidal waves, and in Figs. 2 and 3 the principal properties of such waves are shown diagrammatically.

Fig. 2 gives the wave-length and wave velocity in terms of the wave period. These quantities can be easily determined from the limiting cycloidal form, for at the crest in this case the weight of the particle is just balanced by the centrifugal force in the orbit, and the particle in the crest moves with the same velocity and in the same direction as the wave, so that $4\pi^2 a/T^2 = g$, $v = 2\pi a/T$, and $\lambda = gT^2 2\pi$, where a is the radius of the generating circle of the cycloid, v the wave velocity, and λ the length of a wave the period of which is T.

It is easy and convenient to remember that a wave the period of which is 1 second is nearly 5 ft. long, and that a 6-second wave is nearly 180 ft. long and has a speed of 18 knots.

Below the surface the amplitude of the wave motion decreases exponentially with the depth, and if r is the amplitude at depth D, $r = ae^{-\kappa D}$. The constant κ can be determined by the consideration that if in still water a certain portion is bounded by two level surfaces, that portion must retain the same volume when the level surfaces are transformed into equipotential trochoidal surfaces by the wave motion. From this it is found that $\kappa = 1/a$, so that for every

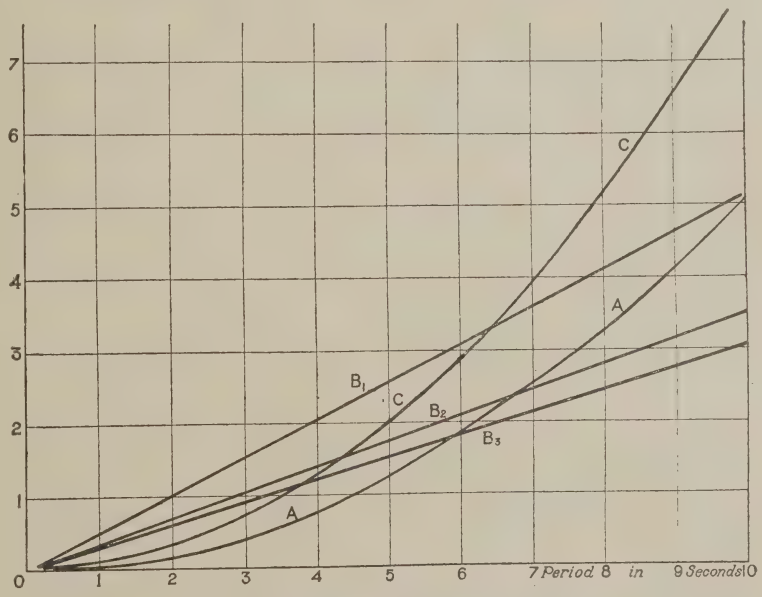

FIG. 2.—Relation between the periods, wave-length, and velocity of trochoidal waves.
Ordinates of A × 10² = wave-length in ft.
" $B_1 \times 10$ = velocity in ft. per sec.
" $B_2 \times 10$ = " miles per hour.
" $B_3 \times 10$ = " knots.
" C × 10 = amplitude of corresponding cycloid, in feet.

trochoidal wave the amplitude is reduced to $1/e$ of the surface value at a depth equal to the radius of the generating circle of the corresponding cycloid.

The reduction of amplitude is shown to scale in Fig. 3. It is worth notice that the still-water level of the sea does not coincide with that of the centre of the generating circle of the trochoidal surface, the

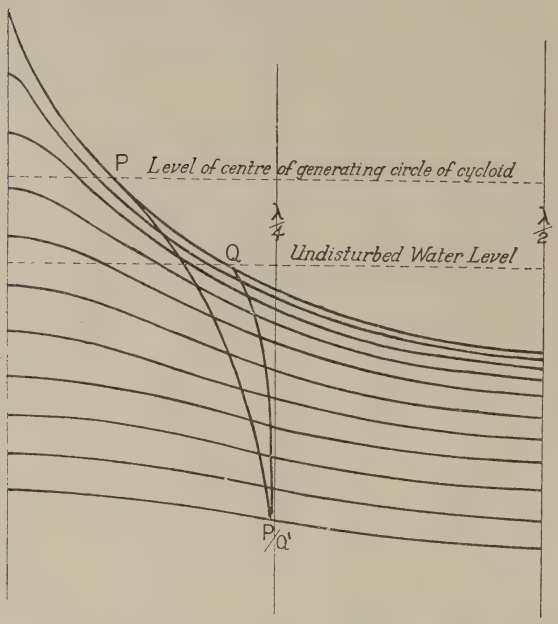

FIG. 3.—Equipotential surfaces showing the reduction of amplitude of the wave motion at different depths below the surface. The upper curve is a cycloid. For each succeeding curve the centre of the generating circle is lowered by $\frac{1}{4}$ of the radius of the generating circle of the cycloid. The intersections of the curve PP with the equipotential surfaces are the levels of the centres of the respective generating circles, and the intersections of QQ′ with the same are the still-water levels corresponding to each.

level in question being determined by the equality of the volumes of the raised and depressed parts of the fluid. This requires the equality of the shaded areas in Fig. 4. The intersections of the curve QQ′ in Fig. 3 with the equipotential surfaces give the still-water level of each, the intersections of PP being at the level of the centres of the generating circles. What the maximum height from trough to crest in

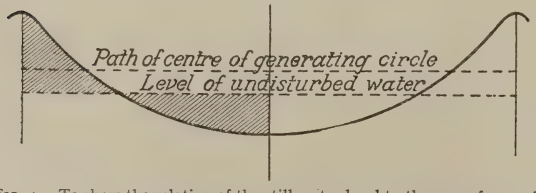

FIG. 4.—To show the relation of the still-water level to the wave form. The water raised and depressed above and below this level must have the same volume, which implies the equality of the shaded areas in the diagram.

ocean waves may be has never been accurately measured. This could be readily determined by photography in the following way: Let two cameras be fixed back to back with the axes of their lenses in the same line, and let a pair of such double cameras be used at different levels on board ship, simultaneous exposures being made with the cameras pointing in approximately the same direction. The four pictures thus obtained from each exposure would then give the data necessary for determining the height and length of the waves. Breaking waves more tha 600 ft. from crest to crest have been encountered, an had their form approached a cycloid, the height woul have been of the order of 200 ft. The most trust worthy guesses, however, do not, I believe, exceed quarter of this amount or less, and this is evidenc so far as it goes, that long waves of large amplitud depart from the trochoidal type, at any rate near th crests, although in other parts the difference i probably small.

Experience shows that these slopes are often stee enough to produce something like a calm in the lee o the crests, and to get an idea of the effect of the win on the wave in these conditions, it may be assume that, except near the crest, the motion is trochoida and that from A to B in Fig. 1 the atmospheri pressure on the surface is the same as if the wate was still, while from B to C it is increased by som fraction θ. In this part of the wave the orbits o the particles are convex to the direction of the wind and the excess of wind pressure, though not affectin the velocity of the particles, is equivalent to a reduc tion of the centrifugal force by an amount proportiona to that excess. From these two conditions, namely constancy of the particle velocity and reduction o centrifugal force, it will be found that for a reductio in the latter by some fraction θ, the radius of th orbit and the period are both increased by the same fraction, so that the original radius r and period T become, between B and C, $r(1+\theta)$ and $T(1+\theta)$, and in every complete period this growth would be repeated. Thus each wave formed by the wind may be considered as having different periods in different parts of its length, but the average length will continually increase. As stated above, the pressure of the wind has no effect on the orbital velocity of the particles, but the surface drag, acting only or chiefly on the windward slopes, will increase that velocity, and therefore also the amplitude.

Until experiments have been made on the action of wind on water, it seems scarcely worth while to attempt a quantitative estimate of the rate at which waves increase either in length or amplitude. It is obvious, however, that the rate is slow, for long waves are only formed on large water surfaces and after a considerable time. Experiments on the distribution of pressure on wave forms might be easily tried on solid models in any wind channel, but for the experimental production of wind-waves a rather more elaborate equipment would be required. The cost of this need not be large if any of the copies of Froude's experimental tank could be made available. Let a rectangular chamber, consisting of roof and sides only, say 3×6 ft. in section and some hundred feet long, be suspended in the tank, so that 3 ft. of the sides are immersed and a 3 ft. square channel left over the water surface; air currents of known velocity could be sent through this and the waves formed examined through suitable glass panels in the sides.

If the channel were 300 ft. in length, waves near the exit might probably reach a length of 2 feet, but a reference to Fig. 3 will show that the amplitude of the motion 3 ft. below the surface would be very small, so that the wave motion in the channel would have but little effect on the rest of the water in the tank. An efficient wave absorber (not merely a shelving beach) would be required to deal with the emergent waves. Experiments on the lines indicated above would, I believe, give valuable results not only as regards the generation of waves, but also as to the effect of wind in promoting ocean currents.

The *St. George* Expedition to the Pacific.

WITH reference to recent newspaper notices of the ork being done by the scientific staff of the *St. George* xpedition to the Pacific, the members of the Scientific xpeditionary Research Association will be greatly bliged if you will give the courtesy of your columns the following brief résumé of the results obtained date.

The expedition reached the Isthmus of Panama on ne 9, 1924. After a short stay in the Canal Zone, evoted by the staff to assiduous collecting, the *t. George* carried out a lengthy cruise to the various opical islands of the Eastern Pacific, including the earl Islands in the Gulf of Panama, Gorgona, off olombia, and the Galapagos; Cocos, Coiba, and aboga islands were also visited. Very large zoo- gical collections were made at these islands, and is likely that a considerable number of new species nd varieties have been obtained. Small mammals ave been captured by Mr. P. H. Johnson at all the lands; these should prove of notable interest, as ew specimens have been obtained there previous to ur visit. They include numerous rats exhibiting a ide range of variation, particularly in the Galapagos.

Much attention has been given to the birds by ieut.-Col. Kelsall; up to the present more than 300 pecimens have been obtained, a number smaller than xpected, due to the difficult but unavoidable con- itions that often prevailed.

The entomologists have had conspicuous success, heir collections being most extensive. Miss Chees- man's attention has been devoted in the main to hose groups not usually collected, and which in onsequence are required to fill gaps in the British Museum collections. It is probable that some of he species will prove to be new, but it is impossible o ascertain this until they have been worked through y specialists. Lepidoptera and Coleoptera, collected y Mr. C. L. Collenette with the assistance of Miss ongfield, are very well represented; special attention vas devoted to the less conspicuous forms as being ikely to be of greater interest than the large and howy ones. Early stages have been described and reserved wherever possible; many ecological facts ave been recorded and should prove of great interest.

Dr. C. Crossland has made large collections of Polychæta, Nudibranchs, and Polyzoa, and Mr. J. Hornell, extensive series of Mollusca, marine and errestrial. It is expected that these will afford nost useful data for the settlement of synonymy nd consequently for better knowledge of geographical listribution. At least five Atlantic species of poly- chætes have been found in the Panama region, indicating that an appreciable number will be found common to the Atlantic and the Pacific when the collections are systematically examined.

Large numbers of flowering plants were gathered in the principal islands visited; those from Gorgona have been received at home already. We understand from a cable received a few days ago that the authorities at Kew place considerable value upon them; indeed, in consequence of their representations it has been decided to pay a second visit to this interesting island, in order to make the botanical material as complete as possible.

Geology has had adequate attention from Mr. L. J. Chubb, who has amassed an extensive series of notes and rock specimens from the various islands.

The outstanding result of the expedition, so far as can be judged at present, has been the discovery by the undersigned of several series of figures graven upon large boulders lying between tide-marks on the eastern shore of Gorgona. The most numerous were two series of archaic figures among which are distinguished what seem to be rude representations of sun-gods and a stepped pyramid, together with figures of monkeys, birds, and other animals. Besides these are two comparatively modern sculptured portraits, one perhaps of Incan age, the other referable to the buccaneering days of the eighteenth century.

A number of stone weapons and implements were also found, associated with potsherds of considerable interest. Advantage is to be taken of our pending return visit to search the island thoroughly for further archæological remains.

JAMES HORNELL,
Scientific Director, *St. George* Expedition.

Panama, September 24.

Optical Records and Relativity.

PROF. LLOYD MORGAN, in his interesting and most original and suggestive article, "Optical Records and Relativity" (NATURE, October 18, p. 577), sums up his argument in sixteen questions. These raise a variety of problems, but are all directed to the conclusion that we may accept the physics of relativity and yet find that the scientific creed of classical mechanics stands in no need of revision. The crux of his whole position appears to me to lie in the answer to his question 6, which he expects to be affirmative, but which must in my view be emphatically negative. The question is: "May we, on the basal principle of relativity, give primacy in 'reality' to either set of events [optical records and their distant source-events], . . . since each is acknowledged as physically 'real' in the same sense?" Surely the answer is that the source-events are, in the theory of relativity, four-dimensional, while the optical records in any aspect of them are only two-dimensional, and the latter cannot therefore have primacy. To say that it is indifferent which we regard as primary, because both are real in the same physical meaning, is like saying that because the map of a country is physically real in the same meaning as the country of which it is the map, we may therefore give primacy either to the country or to the map?

Can I have misunderstood my friend Prof. Lloyd Morgan? I should have thought he would have agreed that his question had been finally answered in Berkeley's "Theory of Vision."

In directing attention to this one point I have observed the condition laid down in the first paragraph of the article, and have dealt only with the relation of two orders of physical reality. I have not raised any question concerning theory of knowledge.

H. WILDON CARR.

The Athenæum,
Pall Mall, S.W.1.

SINCE "Theory of Knowledge" opens up very wide issues, I sought to focus one salient point, namely, psychological reference. No doubt we here come down in the long run to the nature of mind and its relation to physiological events in the body. But my aim was to deal with the retinal record as what Prof. Whitehead calls a percipient event or a sensorium, that is, a state of the body. The question I raised is this: What is "the mind" in some way up against in vision? Is it the percipient event as record? Or is it the distant event with which this percipient event is co-related?

Believing that physical relativity is concerned with *this* co-relation, I led up to sundry questions. Prof. Wildon Carr in his courteous letter regards as crucial the answer to one of them (No. 6). The external "source-events" are, he says, four-dimensional; but

" the optical records in any aspect of them are only two-dimensional, and the latter cannot therefore have primacy."

I find it difficult to understand in what aspect the record on the retina *as a curved surface* is two-dimensional only. I submit that for fruitful co-relation any percipient event is four-dimensional. When, owing to retinal curvature, that which on other grounds we call a straight line is for appearance in some measure deformed, the question arises: Which are we to acknowledge as "really" deformed, the something out there or the percipient event in the record? On the basal principle of physical relativity, may we give primacy to either?

C. LLOYD MORGAN.

Organisation in Chemical Societies.

IN spite of Prof. Philip's able defence (NATURE, October 25, p. 609), it must be confessed that Dr. Travers' objections have much point. It is surely the main business of the Chemical Society in the first place to publish the discoveries of its members, and in the second place to maintain a reference lending library for the benefit of its members. It is doubtful if it should undertake the publication of Abstracts or of Annual Reports unless these pay their way. This is educational work simply, and might reasonably, especially in view of the great industrial importance of chemistry, be financed out of public funds. A Government Department, such as that of Scientific and Industrial Research, might quite well be expected to undertake the publication of chemical abstracts, of chemical patents similar to the publication of Friedländer, and of chemical books of reference, organic and inorganic, frequently revised, on the lines of Beilstein and Stelzner.

J. E. MARSH.

University Chemical Laboratory,
Oxford, October 28.

PROF. PHILIP would have been well advised if he had struck out the last paragraph of his letter in NATURE of October 25. He may have found it satisfying, but it does not accord with the usages of professional controversy, nor does it strengthen his reply to my criticism.

I must point out that I did not attempt to deal with the finances of individual societies. That the Chemical Society has temporarily waived its entrance fee has nothing to do with the fact that 15*l*. is an undue tax on chemists who wish to belong to British chemical societies. Prof. Philip practically admits that American Chemical Abstracts are superior to the British equivalent. They cover "a wider area," a fact which, for some reason he does not give, he does not consider to be an advantage. They are published as a whole in *octavo* size, instead of half in *octavo* and half in *quarto*. One does not have to walk from one set of shelves to another to look up references in any one year. If Dr. Philip will accept a constructive suggestion, it is that his Committee should follow the lead of the United States in these respects.

My experience of the Chemical Society's library has been unfortunate. I have frequently been told that I could not have direct access to series of journals, because members were not admitted to the room where the journals were kept, because indexers were working in the room, etc. As to the meeting-room, on this point Prof. Philip is silent; most members of the Society are inclined to eloquence on the subject.

This state of affairs will continue so long as the various chemical societies continue to cherish their individuality to the extent of preserving absolutely distinct offices, staffs, etc. At the moment they may be co-operating on paper; actually they are in active competition for members, using all the art of advertisement, including the unique offer of some of the cheapest chemical qualifications in the world.

The Physical Nature of Verse.

IF Prof. E. W. Scripture (NATURE, October 11, p. 534) had said that *normal English* verse was *mainly* a matter of rhythm—instead of saying that verse is purely a matter of rhythm—he would have been in line with ordinary opinion to-day. I have myself taught this, at Cambridge and elsewhere, for a quarter of a century. Prof. Scripture contributes nothing new except his method of research and the unnecessary word "centroid." His conclusion is too sweeping, and at the same time defective. The works of Homer, Pindar, Virgil, Horace, and Ovid are verse; and in them we are obliged to take account of quantitative feet. Shakespeare's blank verse line is rhythmic; Milton's is rhythmic and quantitative as well; both observe the principle of number. One of the great æsthetic principles, that uniformity shall admit of variety, so that we receive a continual satisfaction of expectation, mingled with recurrent surprise, would be thwarted if verse were written solely on Prof. Scripture's principle.

Old English verse was of this type:

Áthelstan sóvran	of eárls the lórd,
Bárons' beígh-gìver,	and his bróther álso,
Édmund Átheling	of éndless fáme
Slέw in báttle	with their swórds' édges
Thére at Brúnanbùrgh.	

Each half-verse had two stresses, and would admit a third, a half-stress; and the two were linked by alliteration.

Geoffrey Chaucer dropped the alliteration, introduced rime, number, *and the suggestion of musical rhythm*. He wrote, for instance:

Whán that Aprílle	with his shoúrës soótë
The dróghte of Márche	hath pérced to the roótë,
And báthëd èvery veíne	in swích licoúr,
Of which vertú	engéndrëd is the floúr . . .

He managed the suggestion of musical stress by keeping two rules: (1) a stress must fall either on the fourth or the sixth syllable, unless stresses fall on the second, eighth, and tenth; (2) a stress must always fall on the tenth syllable, and it must be a full stress unless a full stress has fallen on the eighth syllable. In this way he combined the free rhetorical rhythm of the pure English verse with the (substantially indicated) musical rhythm of certain foreign verse.

Nearly all our good verse, everything that can be called classical, combines these two principles.

As for the ancient classical feet, when we mention them nowadays in describing English verse we use a certain licence. By "anapæst" we do not mean two short syllables followed by a long syllable, but two unemphatic syllables (interstresses) followed by an emphatic syllable (a stress). In that sense, for example, Swinburne's chorus in *Atalanta*, "When the hounds of Spring are on Winter's traces . . ." may be described as anapæstic.

Curiously enough, Prof. Scripture (in my view) marks

mistaken emphasis in one of the two examples in which he exhibits his "centroids." Hamlet's line would run :

To bé or nót to bè : thát is the quéstion.

Prof. Scripture is right in exalting rhythm as a main principle in English verse. He is clearly wrong in saying "it has no metre." E. W. LUMMIS.

The Spectrohelioscope.

IN the issue of NATURE for October 25, p. 628, is published an article by Prof. G. E. Hale on the spectrohelioscope. It may be of interest to readers of NATURE to know that, so early as 1912, I made experiments with such an instrument, using a rotating disc in which was cut a number of radial slits. Preliminary experiments were made and a rough model was constructed by the kind help and suggestions of Mr. F. Twyman, who also described the method to Prof. R. W. Wood. Unfortunately, owing to the pressure of more important work, these experiments were abandoned and the model dismantled, but not before certain conclusions were arrived at.

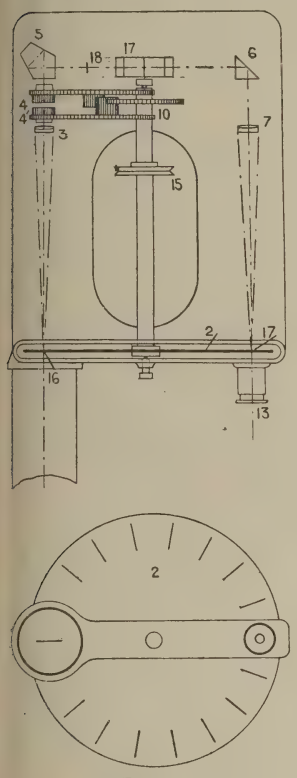

FIG. 1.

In January of 1923 the matter was taken up again and a series of measurements made and experiments carried out, to see if an instrument could be designed and constructed. There are certain difficulties to be met with, and one of these is to maintain an exactly similar movement of the image of the collimator slit on the corresponding slit passing in front of the eyepiece, but this can be overcome. I do not see any reason why a spectrohelioscope built on rotating sector principle should not give excellent results, and there are further uses to which such an instrument could be applied.

A drawing of one of the models suggested was forwarded to several British astronomers in June 1923, including Prof. Fowler, of the Imperial College, who also commented favourably upon it. Fig. 1 is from a drawing of one of the instruments proposed. In place of the compound prism shown, a replica diffraction grating can be used with advantage.

The instrument consists of a rotating disc (2) in which are cut a number of radial slits. The light which forms an image of the sun or other object comes to a focus on the rotating disc at (16). The light passes through the slit and is collimated by the object glass (3), and passes through the deflecting system (4) and (4′) and the pentagonal prism (5). The dispersing element (17) is a high dispersion compound prism which forms an image by means of the object glass (7) on the disc at position (17). This slit image will be in monochromatic light and will pass out through the slit at (17) into the observing eyepiece (13).

When the instrument is in use, the disc (2) is rotated, by means of the pulley (15) and an electric motor, at a speed which will eliminate flicker, and the object is then seen in monochromatic light corresponding to that for which the compound prism is set. When light of a different wave-length is required, a suitable deflecting prism is interposed at (18). The degree of purity will, of course, depend on the width of slits employed. The deflecting prisms (4) and (4′) are used to correct small errors of deviation due to the dispersing prism (17) and are driven by suitable gearing to make one complete revolution as the entrance slit passes the object.

Abney Sectors in Photometry.

IN the issue of NATURE for September 27, p. 466, there appears a letter from Mr. G. F. Wood describing, with illustration, a type of photometric sectored disc, the transmission of which is a function of the distance from the centre of the disc.

It may be of interest to Mr. Wood and to readers of NATURE to know that a disc of exactly this type was invented by Dr. E. P. Hyde in 1912, and described in an article in the *Astrophysical Journal*, vol. xxxv., No. 4, May 1912, page 237.

It should be noted that this type of disc can, in general, be used only where the light beam is of small dimensions compared with the dimensions of the disc ; otherwise, there will be a non-uniform field of view. The disc invented by Dr. Hyde was intended for use with a spectrophotometer where the light beam is limited by the width of the slit.

In this connexion, I understand that the firm of Franz, Schmidt and Haensch, makers of photometric apparatus, list Dr. Hyde's disc in their catalogue as an auxiliary to their spectrophotometer.

FRANCIS E. CADY.

Nela Research Laboratory,
Nela Park, Cleveland, October 16.

Popular Science Exhibitions.

YOUR commendation of the Royal Society's Exhibition of Pure Science at the British Empire Exhibition, Wembley, will, I feel sure, be welcomed by all readers of NATURE. I hope you will allow me to suggest that it might be supplemented by a word of praise for the scientific chemistry exhibits, which, owing to the admirable enterprise and liberality of the chemical manufacturers, were detached from the science exhibits of the Royal Society and placed as a sort of intellectual heart in the centre of the fine display of manufacturing chemistry in the Palace of Industry. Incidentally also, this gave rise to the striking book on "Chemistry in the Twentieth Century" and to the publication of a series of popular pamphlets which have had a large sale in the Exhibition.

It is right to add a word of acknowledgment of the debt due to Mr. W. J. U. Woolcock, the manager of the Association of British Chemical Manufacturers, for the great part he has played in putting so clearly in evidence the creditable state of British chemistry, both pure and applied. A. S.

If the Earth went Dry.[1]

By Sir NAPIER SHAW, F.R.S.

THE various countries of the globe differ from one another in respect of dryness, though none are literally dry, year in and year out. Still some are very nearly dry; others are moist, and some, comparatively speaking, wet. Herein consists one of the main causes of the complication which students of the physics of the atmosphere have to face.

For a meteorologist, water in the form of vapour is the most important constituent of the atmosphere; it provides not only the material for clouds, rain, snow, and hail, but also the means of supplying the energy which makes those things possible. Recent investigations have made it clear that the important functions attributed somewhat loosely in meteorological literature to warm air really belong to the water vapour which the warm air carries. We may well therefore ask the question, "What on earth should we do without water?" What would meteorology be like if its warm air were never saturated and never could be saturated? The answer to the question is, "Very little would be left; but still something." It is that "something" to which I wish to direct attention. "What would be left of meteorology if the earth went dry?"

As a subject it is, of course, hypothetical. Water is an important constituent, not only of the atmosphere but also of all living material, so absolute prohibition in the sense in which I am using the term would put an end not only to that part of meteorology which I may call the joy of its life, but also to life itself in any form. So far as I know, it would be futile to put the question to a biologist. It is not so for the meteorologist. Although the most familiar conception of the meteorologist, the spontaneous ascent of warm air through its environment by what is called convection, would disappear, there would still remain quite unimpaired and even enhanced the spontaneous descent of air by cooling on a mountain slope and also a peculiar form of the ascent of warmed air by the building up of a layer of air in convective equilibrium—a new conception of considerable interest which gives a true representation of the convection of warm air as distinguished from saturated air.

A General View of Atmospheric Structure.

I start from a certain idea of atmospheric structure, which, though not novel, may require setting out. I will ask you to regard the meteorological atmosphere as being an envelope of some twenty kilometres' thickness, with a structure of the same type as the stratosphere which has been identified in our own upper atmosphere. By a stratosphere I mean a thermal structure expressed by approximately vertical isothermal surfaces which surround the polar axis like a series of collars projecting vertically outward from successive parallels of latitude. Such a structure would require a certain circulation of air, in order to balance the distribution of pressure which is inevitable when there are vertical columns of different temperature; but that being provided, the structure would be an extremely stable atmosphere, impenetrable by any convection. That is as it should be; because the structure is only possible if vertical convection is ruled out. Vertical convection of any sort would mix up the layers and transform the isothermal structure into some sort of approximation to the labile state of convective equilibrium. Any convection would be a step in that direction.

Taking the structure of the stratosphere as the original idea, we may say that the lower layers of our own atmosphere have been modified by convection, with the aid of water vapour, and have been converted into a state which approximates much more nearly to that of convective equilibrium than to the isothermal conditions of the stratosphere. The part of the atmosphere thus modified we call the troposphere. In this region temperature is arranged in layers which are nearly horizontal instead of in nearly vertical sheets or columns. Our present troposphere is not uniformly thick; it extends from the surface of the earth upward through about seventeen kilometres in the equatorial region, and about half that height at the poles. Its upper boundary, called the tropopause, may be said to mark the present limit of the operation of convection. If convection became more active, the troposphere would be enlarged at the expense of the stratosphere; if on the other hand convection became less active, the boundary would be lower, the stratosphere would come down nearer to the earth; and if there were no convection at all, the atmosphere would be all stratosphere.

We may therefore regard the troposphere as the result of persistent excavation by quarrying, carving, or nibbling of the under side of a stratospheric atmosphere by convection of one sort or other which originates in the warmth and moisture developed at the earth's surface or the loss of heat in the absence of the sun. In our present atmosphere convection is largely dependent upon water vapour, hence our first conclusion is that if there were no water vapour, the excavation would be greatly reduced and the stratosphere would be brought down much nearer to the surface and only interfered with by such convection as belongs to dry air.

It is possible that in the course of years this reduction of convection might affect the temperature of the stratosphere but its immediate results would be limited to the troposphere, and its effects upon the body of air comprised within the troposphere are dynamical as well as thermal. The troposphere may be said to form the flywheel of the atmospheric engine. It is in a state of perpetual motion, which we call the general circulation of the atmosphere, as the dynamical effect of heat received from the sun by radiation, communicated chiefly at the ground level and afterwards radiated into space from the earth's surface and the atmosphere. The working of the atmospheric engine would be much simplified if there were no water vapour, because then, without serious error, the atmosphere might be regarded as perfectly transparent both

[1] Paper read before Section A (Mathematics and Physics) of the British Association at Toronto on August 8.

or the solar radiation by which the heat is gained and or the terrestrial radiation by which the heat is lost.[2] Loss or gain would take place only at the surface and the balance of loss or gain of heat would be the result of a comparatively simple account.

The Balance of Gain and Loss of Heat.

As a prelude to the question of downward convection, which is applicable equally to dry air and moist air, let us examine the question of the balance of gain of heat from the sun and the loss of radiation from the ground.

Taking a station such as Davos, the diurnal and seasonal isopleths of the intensity of solar radiation, which is referred to a surface normal to the sun's rays, shows that the diminution of the intensity with the increasing obliquity of the sun's rays is due to absorption by the atmosphere, principally by water vapour. If there were no water in the atmosphere, the intensity of solar radiation would reach and remain at the amount indicated by the solar constant throughout the period of sunlight, changing instantaneously to zero with the disappearance of the sun at sunset and recovering its full activity at sunrise. That activity is about 1·93 gram calories per square centimetre per minute, equivalent to 135 kilowatts per square dekametre or 1·35 kilowatt (2 horse-power) per square metre.

I digress for a moment to direct attention to the vastness of the power of the sun. Some days ago, looking at the Montmorency Falls, a distinguished engineer suggested that the energy represented by the Falls might be 20,000 horse-power. The power of sunlight upon an area of 200 yards by 100 yards, about four acres, would exceed that amount—if the whole of the energy of sunlight could be converted into work, as practically the energy of a waterfall can be.

We have supposed the area to be at right angles to the sun's rays. To get the amount on a square dekametre of horizontal surface, we must multiply the figure for normal incidence by the sine of the angle between the sun's rays and the horizontal surface, the sine of the sun's altitude. As the sun recedes from its noon altitude the intensity of its radiation decreases gradually from its noon value to zero when at sunset the sun is at grazing incidence.

To set against this gain of energy by solar radiation we have the loss of heat by radiation into space, which, if the atmosphere be perfectly transparent (as we will assume dry air to be), depends upon the fourth power of the temperature, and nothing else, except the radiating power of the surface. Taking that radiating power as that of a perfectly black body, as we may fairly do if there is no ice or snow, the loss of heat by radiation according to Stefan's law is σt^4 where t is the absolute temperature and σ is a constant, namely, $5{\cdot}72 \times 10^{-12}$ watts per square centimetre.

Thus we get the following table for the sun's altitude when there is a balance of solar and terrestrial radiation for a horizontal surface:

Temperature.		Sun's Altitude for Balance.	Temperature.		Sun's Altitude for Balance.
Tercentesimal.[3]	Centigrade.		Tercentesimal.	Centigrade.	
200	−73	3½°	310	+37	20¾°
210	−63	4¼°	320	+47	23¾°
220	−53	5 °	330	+57	27 °
230	−43	6 °	340	+67	31 °
240	−33	7¼°	350	+77	35¼°
250	−23	8½°	360	+87	40 °
260	−13	10 °	370	+97	46 °
270	− 3	11¾°	380	+107	53¼°
280	+ 7	13¾°	390	+117	62¼°
290	+17	15¾°	400	+127	79¼°
300	+27	18 °	402	+129	90 °

The Upward Convection of Dry Air.

Since the air is dry it must necessarily cool on rising to the maximum extent of 1t per 100 metres. It can only penetrate the air above it if the lapse rate of the environment is of the same magnitude. That is the condition for what is called convective equilibrium (Bjerknes's barotropic condition). Consequently, upward convection by warmed air can only occur by building up a layer in convective equilibrium; and then, an infinitesimal increase of temperature at the surface would cause the passage of the warmed air to the top of the existing convective layer and its subsequent extension with only an infinitesimal difference of temperature beyond the existing top. When the penetrative convection caused by water vapour is non-existent, we are limited to this gradual piling up of a layer which differs only infinitesimally from convective equilibrium and increases in thickness with the continuance of the solarisation of the ground. Certain amplifications of this statement are necessary when the solarised surface is not horizontal, and locally when the angle of elevation varies from place to place; but, subject to that reservation, we may understand that if the earth were dry, upward convection would mean the compilation of a layer of air in convective equilibrium.

We may ask how far the layer would extend under given conditions of solarisation and the answer depends upon the condition of the atmosphere when the solarisation begins. From our knowledge of the maximum and minimum temperatures in a dry atmosphere, such as that of Egypt, we may conclude that the convective layer which is formed during the day is abolished during the night by the turbulence due to winds operating upon the surface layer cooled by terrestrial radiation from the ground.

For the present, let us suppose that the diurnal range at the ground is 20t (the normal range at Helwan), and that this range falls off uniformly with height until the undisturbed level is reached. Let h be the height of that level and let d be the mean density of the column. Then by equating the amount required to warm the atmosphere with the heat gained during a day under a sun which is vertical at noon, and

[2] This statement may be admitted for the purpose of computation in this paper, although, according to observations of Anders Ångström, "the perfectly dry atmosphere has a radiating power as great as 50% of the radiation of a black body at the temperature of the place of observation" (Smithsonian Misc. Coll., vol. 65, No. 3, p. 88, 1915).

[3] Tercentesimal temperature is the temperature measured in centigrade degrees from a zero 273 degrees below the normal freezing point of water. It is approximately equal to the absolute or "Kelvin" temperature, but there is a technical difference between the two which cannot always be ignored. In this as in other papers a unit step on the tercentesimal scale is denoted by t.

allowing for a loss by outward radiation to the extent of that corresponding with the mean temperature for Helwan, we get an equation for h. This equation can be solved with the aid of the pressure equation and gives approximately 2 kilometres for the height of the daily convective layer at Helwan.

Similar equations can be got for other latitudes, and by considering the case of a conical surface in the polar regions with its vertex 2 kilometres above sea level and a base of 500 kilometres radius.

We proceed from the knowledge that a slope is required in order to cause a downward flow at all, and that in the polar regions a pool of cold air is formed during the seasonal night with the coldest air at the bottom, in spite of the fact that descending air is automatically warmed to the extent of 1° for every 100 metres of descent. We assume further that

The Downward Convection of Dry Air: Katabatic Winds.

Downward convection along a surface which is losing heat by radiation will proceed with undiminished or even increased intensity when the earth is dry, and we may form a rough estimate of the result of the process

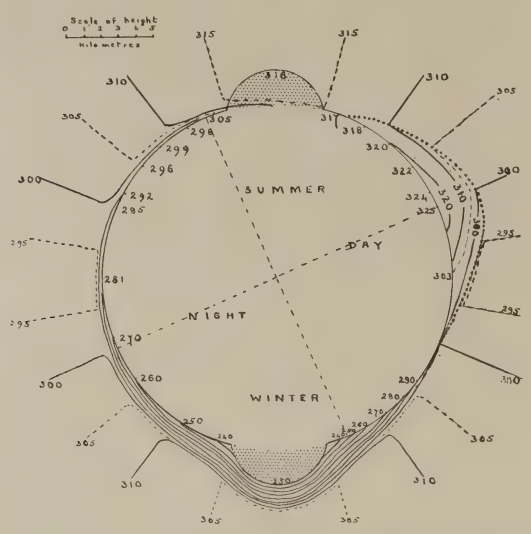

FIG. 1.—Distribution of temperature in a dry atmosphere at the northern solstice on a globe with hemispherical polar caps.

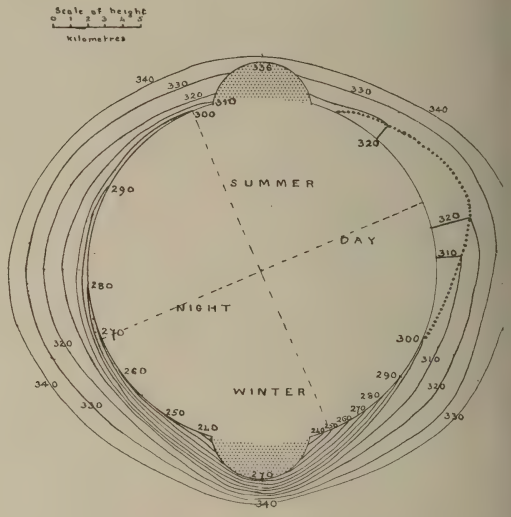

FIG. 3.—Distribution of potential temperature corresponding with Figure 1.

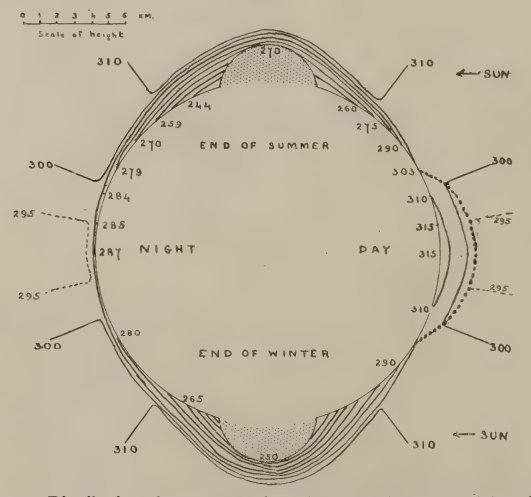

FIG. 2.—Distribution of temperature in a dry atmosphere on a globe with hemispherical polar caps at the autumnal equinox of the northern hemisphere.

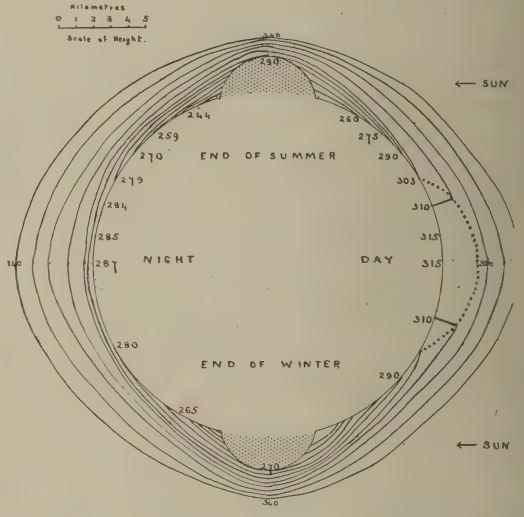

FIG. 4.—Distribution of potential temperature corresponding with Figure 2.

The boundary of the convective atmosphere is indicated in each diagram by a line of dots.

the average height of the convective layer works out for the year as follows:

Latitude	0	10	20	30	40	50	60	70	80	90
Solar radiation per day (gm. cal. per cm.²)	916	904	869	807	725	629	521	435	393	380
Height of the convective atmosphere (km.)	2	2	1·9	1·8	1·6	1·4	1·1	1·0	0·8	0·8

Mean values for the year have no real practical application for the polar regions, but let that pass.

ring the winter the air at the base does not get
sistently and continually colder from the first
idence of shadow to the end of night, but
ches a steady state in which the further cooling of
air at the foot of the slope is prevented by air
ning down under the influence of the loss of heat
m the slope. The descending air has its tempera-
e raised by the increase of pressure; but it loses
t to the cooling ground over which it marches.
dy convection will bring a certain thickness of the
cending current into contact with the ground.
e increased temperature of the descending air is
d to wash away, so to speak, the loss of heat by
liation from the whole slope. When a steady state
s thus been reached, if we suppose the temperature
the base to be maintained at 10t below that of the
nmit and the turbulence to be sufficient to mix up
surface air to a thickness of 50 metres, we find that
will be necessary to have a radial outflow of 300 km.
r hour over the periphery of the circle of 500 km.
lius in order to wash away the result of radiation
d keep the thermal balance.

That is a tremendous wind and perhaps we have cause
be thankful that the polar regions are not entirely dry.
ere is, of course, ample opportunity for mistakes in
e assumptions and even in the arithmetic; but no
anges either in assumptions or in arithmetic can, so
as I can see, enable us to escape from the con-
sion that katabatic winds on polar slopes are a very
l and very potent phenomenon of the atmosphere,
ich would certainly not be diminished by its
coming dry.

Diagrams of Temperature and Potential Temperature.

With the physical principles thus enunciated I have
deavoured to construct diagrams representing the
stribution of temperature and potential temperature
er the earth at the solstice and equinox, making use
the information about diurnal range and seasonal
riation given by extant observations in regions that
e approximately dry. I use both temperature and
tential temperature in consequence of the interesting
ciprocity between them. We have only three types
condition: stratosphere, convective equilibrium,
d downward convection. In the stratosphere, iso-
erms are vertical, lines of equal potential tempera-
re horizontal; in the convective equilibrium, exactly
e reverse is the case. Where downward convection
maintained there is horizontal stratification with
version of temperature.

As illustrations of the material upon which the
ures of the diagrams are based, I quote the following:
1. Seasonal variation of thermal structure of the
lar atmosphere at Maudhavn, North Siberia, Lat.
½° N. from H. U. Sverdrup, Maud-Ekspeditionens
denskabelige Arbeide, 1918–19.

Temperatures at various Dates.
(Tercentesimal Scale.)

eight in Metres.	Feb. 26.	Mar. 22.	April 11.	June 17.	July 11.
0	229	241	253	274	280
200	239	240	251·5	272·5	279
1000	246	247	259	271·5	274

There is transition from continuous and very rapid *increase* of temperature with height, 17t for 1000 metres, in February (before sunrise) to the common *lapse-rate* of the world, 6t for 1000 metres, in July.

2. Data for diurnal range of temperature in July in dry tropical regions.

Diurnal Ranges.
(Tercentesimal Scale.)

	Mean.	Mean Max.	Mean Min.	Abs. Max.	Abs. Min.	Period.
Wadi Halfa .	304·4	313·8	296·2	322	290	1902–20
Helwan . .	300·3	308·4	294	315·9	289	1904–20
Salt Lake City	..	309	284	312	279	..

On the principles mentioned and with data of this kind culled from various sources, I have made out diagrams of the distribution of temperature in a dry atmosphere at the solstice (Fig. 1) and at the equinox (Fig. 2); also the distribution of potential temperature at the same epochs (Figs. 3 and 4).

The General Circulation of a Dry Atmosphere.

Finally, we have to consider what the circulation of the atmosphere would be in the supposed conditions of dry air. Looking at the diagram of the distribution of temperature, we see that an arrangement of the vertical columns of air round the pole would be the dominant feature, and therefore a vigorous west-to-east circulation round the pole in the upper atmosphere of the higher latitudes, compensated, as it must be, from the principle of conservation of moment of momentum, by a west-to-east circulation partly in the equatorial region.

There is also the flow of air down the polar slopes, which will certainly simulate the procedure which we attribute to the polar front. In the dynamical effects which they produce, the elevations at the poles are indeed the equivalents of very vigorous anticyclones, and the revolution of the earth will take care that the currents which they feed shall produce a circulation opposite to the westerly circulation under which they are formed.

There will be the discontinuities of temperature and of wind velocity typical of the polar front and the corresponding dynamical effects. Even if the earth went dry, the weather of the world would be of the same type as now in respect of general and local circulations; only as regards intensity would those circulations be affected.

If this conclusion be accepted, as I think it must be, we have next to think out what, after all, the effect of restoring the water would be, and then we shall have made a schematic representation of real weather. The thermodynamical aspect of the subject is treated in a paper on the energy of saturated air in a natural environment for the International Mathematical Association, in which the convective energy of a kilogram of air in virtue of its full complement of water vapour is represented by the area enclosed between the curve of environment and the adiabatic curve of saturated air drawn through the point at which saturation is assumed to exist. The amount of energy thus represented is found to vary from zero to 10,000 joules or more per kilogram.

Acoustical Problems.

By Major W. S. TUCKER, D.Sc.

OF all branches of physics, acoustics has probably been the most neglected of recent years; and although a good deal of work is being done in America, the number of investigators working in acoustics in Great Britain is surprisingly small. The War caused a temporary revival of interest in certain aspects of the subject, and a number of papers of scientific value were produced as the result of the application of acoustical methods to the location of submarines, guns, aeroplanes, and mining activities. Very few of the large personnel, however, who were engaged in these problems have continued in this work. Return to the universities of those engaged in teaching and research resulted in a resumption of their pre-War activities.

Yet there are many problems well deserving of systematic study. To give one illustration, the study of the properties of collectors of sound such as trumpets —and all those aspects of sound distribution in which the wave-length is comparable with the dimensions of the object—require further development by the mathematician, although the cases of obstacles large or small as compared with the wave-length have been adequately dealt with. In experimental acoustics many physical laboratories used for instruction are only equipped with apparatus of a very elementary character, and after a brief course in the first year, the students cease to take any further interest in that branch of physics. The shortage of text-books on the subject is another feature, and it is scarcely possible to appreciate how much work has been done in recent years, except by a laborious study of scientific journals, few of which are available in the average college library. Yet there is a growing demand for the solution of problems which are beginning to affect our everyday life, and the calling of "acoustical engineer," or "consultant in acoustics," should be among the professions worthy of a more definite place.

Our mode of locomotion largely involves the production of rapid explosions—only too often inadequately silenced—and our main roads are more noisy than the railroad tracks. In the neighbourhood of our busy aerodromes, noise is continuously distracting, and our quiet countryside has been invaded by the sounds of the low-flying continental traffic.

Our halls and council chambers, now that wood ceases to be an indispensable part of the walls and ceilings, are so resonant that much expense has been entailed in remedying their poor acoustical properties, and if further problems need be cited, the distortion of our speech and music by "loud speakers" is surely a matter requiring something more than the experimental investigations undertaken by commercial firms.

These are only a few of the problems the solution of which will almost certainly be found in the physical laboratory, but in order that they may be dealt with effectively, some attention must be paid to the perfecting of acoustical measurements. The researches of Harvey Fletcher, Knudsen, Minton, and other American physicists have shown what are the limitations of the ear, and although no instrument could be devised combining the extreme sensitivity and large musical range of that organ at the same time, th is ample evidence to show that the ear either absolute or relative measurements should not relied upon. Electrical methods of comparison m ultimately be used, and microphones must be devis in which some simple law must connect the intens of the measured sound with the effect it produc There is a great need for a source of sound which c be accurately reproduced, and can serve as an arbitra unit, worthy to be included among the standards a basis of physical measurement.

One of the chief problems in acoustical research the provision of an acoustical laboratory. If a clos room is chosen, the distribution of sound in the roc is so strongly affected by reflexions of the walls th nearly all experiments involving sound measureme are vitiated. If a siren be employed as a source sound, and the pitch is gradually raised, a given poi in the room may give a maximum of intensity f one note and a minimum for a note of another pitc This effect is overcome to some extent by "lagging the walls of the room with sound-absorbent materi but the effect can still be distinguished, and if o attempts to obtain resonance curves for any acoustic apparatus, these curves will be distorted.

The only means of working satisfactorily is to experiments in the open air, and in spite of difficulti with wind and varying temperature, and possib extraneous noises, good results can be obtaine Measurements of absorbing powers of differe materials have been made, by Wallace Sabine and h associates, by employing rooms in which elabora precautions have been taken to insulate them fro the outer air. In this case values have been deduce from the period of reverberation, the ear being en ployed as the means of estimating the duration the effect. Not only have absorbing powers bee measured, but also the experiments have been develope to such an extent as to measure deafness, and qui recently to estimate the amount of energy given ou by various musical instruments, and by the huma voice. Values of absorbing power for differer materials have been obtained with sufficient accurac to enable architects and builders to improve effectivel the acoustic properties of halls and churches. Tes of reverberation are difficult to carry out if there ar disturbing sounds in the neighbourhood. It is reason able to anticipate that with a pure note source sound and a tuned microphone for reception, mor accurate methods could be devised for measurin reverberation periods—methods which will ignor the "jamming" effect of outside noises.

One of the chief problems in acoustical measure ment is the design of a source of sound in which th note is pure, and the output is fairly uniform through out a reasonable range of musical notes. Develop ments in wireless have introduced to us a very usefu generator of sound in the thermionic valve and it appropriate electric circuits. Alternating current closely approaching a simple harmonic character hav been generated, and the alteration in pitch is accom plished by the simple adjustment of inductance o

pacity. By a process of "heterodyning" familiar to the wireless expert, Cohen has been able to produce a very constant output for cycles varying from 50 to 5000 per second, and these oscillatory currents can be used to actuate "loud speakers." If only the loud speaker were devoid of resonance properties, the problem above referred to would be effectively solved. Another useful piece of apparatus has been designed by E. A. Milne and Fowler in which the simple Seebeck siren is converted into a pure tone generator by so shaping the holes of the disc as to cause the flow of air to alter in quantity by a simple harmonic relation with time. If the pipes supplying the air can be made non-resonant this source of sound is probably the best available. An attempt is being made to devise pure tone centrifugal sirens in which pipes for conducting the air past the ports of the rotating part may be dispensed with, but here we have the disadvantage that acoustical output increasing with the frequency of the note. With apparatus of this character and with suitable microphones, accurate resonance curves can be obtained for various sound receivers.

There are problems of sound transmission through the air which involve large scale experiments and the accurate knowledge of upper winds and temperatures. These might be considered under the heading of meteorological acoustics, and they are of increasing importance in long-range listening for aeroplanes. The work of Tyndall, Osborne Reynolds, Rayleigh, and, more recently, Van Everdingen and E. A. Milne, have resulted in the explanation of those phenomena of variation of range for sounds up-wind and down-wind. Milne has obtained expressions for range and corrections for refraction due to variations of upper wind and upper temperature when these follow a linear law. Explanations of zones of silence at some distance from the source have also been afforded. The Acoustical Section, working for the three Fighting Services and the Department of Scientific and Industrial Research, has been able to verify experimentally some of these laws, and the latter have been very helpful in the design of directional sound-receiving apparatus.

One of the features of recent developments in acoustics has been the production and improvement of the Service sound locators for detection and location of aeroplanes. These instruments will not in general point to the source of sound owing to (1) lag of sound, if the source is a moving one, and (2) the departure of the wave front from the spherical owing to refraction due to wind and temperature variations. The ease with which these instruments can be used depends on the structure of the atmosphere in which, apart from refraction due to the above causes, there are irregularities due to local temperature and humidity variations, and local whirls and eddies.

These variations in the medium have all been grouped under the heading of "acoustic clouds." Contrary to what might be expected, these acoustic clouds are most in evidence on a warm sunny day of good visibility, and are undoubtedly due to unequal heating from the sun's radiation. After sunset these clouds dissipate, and we get, not only good listening as regards range, but also greatly improved powers of finding direction. The blurred acoustical image becomes well defined. On the other hand, a uniform fog is acoustically clear and it is only on the fringes of the fog that sound absorption takes place. Experiments have recently been performed with aeroplanes in which some idea of the dimensions of the acoustic clouds has been deduced. These have been obtained by taking a photographic record of the sound obtained from an aeroplane in flight, and observing the periodicity of the sound fluctuations.

One of the outcomes of the study of meteorological conditions has been the fixing of an "acoustic skyline," which, under adverse wind conditions, always lies above the visual skyline. A source of sound moving through the air may be observed to rise or set over the skyline, with a definiteness almost as complete as the rising and setting of the sun, and when the sound is below the skyline a kind of acoustic twilight is produced. At this stage sense of direction is lost, the sound is diffused, and only arrives at the observer or microphone by scattering.

Other problems involving big scale experiments are connected with the production of powerful directive sources of sound, and include the breakdown of the air as a medium of sound transmission when the displacements due to the source of sound become large.

The foregoing statement merely provides a summary of those problems which are engaging the attention of research workers in acoustics, but they may serve to indicate how very fruitful is this field of investigation for the expert experimental physicist.

Obituary.

MR. A. E. CRAWLEY.

THE death took place on October 21 of Alfred Ernest Crawley, who was well known as the author of several works on anthropological matters. He was born in 1869, the son of the Rev. Samuel Crawley, Rector of Oddington, Oxford, was educated at Sedbergh and Cambridge, and entered the scholastic profession; he abandoned this for journalism in 1908. An adept in several branches of sport, his works on tennis and ball games are of recognised authority. In anthropology, besides contributing to the journals of several scientific societies, to NATURE, and to Hastings's "Dictionary of Religion and Ethics," he was the author of three books of some importance—"The Mystic Rose, a Study of Primitive Marriage," published in 1902; "The Tree of Life, a Study of Religion," published in 1905, and "The Idea of the Soul," which appeared in 1909. Of these "The Mystic Rose" was the best known—it undoubtedly exercised no inconsiderable influence on the anthropological thought of that day, especially in so far as it emphasised the importance of marriage ceremonies, a side of the subject to which Westermarck had then paid too little attention in his monumental study of human marriage.

Certain characteristic lines of thought are common to all Crawley's books, and indeed so early as 1895 he had outlined in the Journal of the Anthropological

Institute his fundamental principle that the aim of analysis of social institutions and religions should be to arrive at the mental attitude of primitive man towards his institutions and beliefs. In his view the study of marriage, for example, had been too exclusively sociological, and his book represented an attempt to bring marriage institutions and ceremonies as well as other primitive customs into the domain of psychology by defining the psychological needs which were satisfied by the magical or religious observances by which they were accompanied. Crawley's work was accurate and scholarly and was based upon wide reading and a critical appreciation of his authorities. Some at least of his work is of enduring value.

Dr. E. O. Hovey.

Edmund Otis Hovey, curator of the Department of Geology and Invertebrate Palæontology in the American Museum of Natural History, had just entered his sixty-third year when he was struck with paralysis in his office and died on September 27. In his younger days Dr. Hovey filled some teaching posts; he was brought by his installation of the mineralogical exhibit of Missouri at the Chicago Exposition to the notice of the American Museum, and entered its service in 1894.

Dr. Hovey was perhaps best known to geologists for his work in connexion with the eruption of Mont Pelé, Martinique, which took place on May 8, 1902. He was immediately sent as representative of the American Museum of Natural History, arrived at Martinique on May 21, and after distributing supplies to the impoverished inhabitants, spent about three weeks in studying the Soufrière on St. Vincent and four weeks on Mont Pelé. His results were published a preliminary report issued by the Museum in Bulletin on Oct. 11 of the same year. In Febru 1903 Hovey was again sent to note what changes h taken place and to extend his studies to the other rec volcanoes of the Caribbean chain; and again in 19 to bring the observations up-to-date. Other expe tions made by Hovey on behalf of the Museum were South Dakota and Mexico.

As museum curator Hovey took a keen interest his professional work, being responsible for seve attractive models in the public gallery. Though charge of the fossil invertebrata, he can scarcely considered a palæontologist. He did, however, c laborate with R. P. Whitfield, and with him produc the very helpful catalogue of the types and figur specimens among those fossils in the American Museu (1898–1901). We have lost in E. O. Hovey a usef worker, a cheery companion, and a constant friend.

F. A. B.

We regret to announce the following deaths:

Prof. W. A. Locey, professor and director of th Department of Zoology, Northwestern Universit since 1896, who was known for his work on th embryology of the nervous system, aged sixty-seven

Dr. Clara S. Ludlow, of George Washingto University and the United States Army Medic School, Washington, who carried out work in th Philippines on the transmission of disease b mosquitoes, on September 28, aged seventy-one.

Prof. G. Pruvot, honorary professor in the Facult of Science of the University of Paris, and formerl Director of the Laboratory of Marine Zoology a Banyuls-sur-Mer (Pyrénées-Orientales).

Prof. W. A. Macfadyen, professor of philosophy i the Transvaal University College, Pretoria.

Current Topics and Events

Great Britain is beginning to appreciate the importance of broadening the education of the mathematician and the scientific worker. In all subjects new knowledge has been and is piling up at a great rate. The universities demand more and more for a degree, and the student is constantly becoming more overloaded. At the same time, the lines of demarcation between the subjects are breaking down, and the importance for every scientific worker of a knowledge of allied sciences is growing greater every day. Sir William Pope expounded this idea in a lecture delivered in July last before the Royal Society of Arts. He pointed out the importance for chemists of a knowledge of physics and the need of a reform by which natural philosophy (that is, physics and chemistry) would become a single whole instead of being made up of half-a-dozen disconnected subjects. He would unite them into one by emphasising the fact that they are all based upon the electronic constitution of matter and energy. The importance of a knowledge of physics to the mathematician was emphasised at the conference held recently at the University College of Southampton, and the October issue of the *Mathematical Gazette* contains a valuable article by Prof. Piaggio on the subject. The main value of this article lies in the author's discussio of the means by which it can be made possible fc the mathematician to attain a knowledge of physic in addition to mathematics within a reasonable time He goes through the various branches of applie mathematics as at present taught at universities an picks out a considerable number of items that coul well be dropped in order to make room for mor important matter.

A correspondent sends us copies of the journal *La Province de Namur*, of June 1 and October 15 containing descriptions of a large pearl, reported b M. E. de Ceuster, of Moustier-sur-Sambre, to hav been found in a coconut. Where pearls come fron has always been a mystery in India, and so long ag as 1240 A.D., a Kashmir physician records them a coming from bamboos, coconuts, heads of elephants fish, etc. Pearls are definite animal concretions c carbonate of lime around a core which may be foreign body, the egg or some part of the body o the organism, or the egg or part of the body of contained parasite. True pearls only occur i molluscs, and they are microscopically and chemicall identical with the nacre—the inner lining of the shell—

all molluscs. Actually the structure consists of a ast number of very thin and corrugated laminæ an organic substance known as conchiolin, holding picules of carbonate of lime. The transparency, the verlapping of the laminæ, the corrugation, and the ngles of the lime spicules give the lustre so well hown in the precious pearls. Somewhat similar unded off concretions may be found in any animal's ody—as Bunyan says, "A pearl may in a toad's ead dwell"—but they are not found in plants, nooth and rounded off in this way. Concretions o occur in the latter, both of calcium carbonate and calcium oxalate, but they are generally rough, and e not formed in layers with a similar basis of onchiolin; a simple test for them would be the resence or absence of plant cellulose. In the East enerally the pearls formed by the giant clams of ne reefs are termed "coconut pearls," as their ppearance bears a resemblance to the cut surface f the kernel of the coconut; they often attain the ze of a pigeon's or small hen's egg, the clams themelves varying up to two feet across. Needless to ay, as they have no lustre, they are of no beauty nd of no value. Any plant concretion that may airly be termed a pearl would certainly be "new to cience."

THE presidential address given on October 23 to he Institution of Electrical Engineers by Mr. W. B. Woodhouse lays stress on the rapid growth of the lectrical industry during the last twenty years and ooks forward hopefully to the future. Mr. Woodouse makes the timely statement that electricity is ot a panacea for industrial and social ills, and so t behoves engineers to speak out just as definitely vhen unjustifiable claims are made for it as vhen it is unfairly attacked. In connexion with ducation, he made the interesting suggestion that a system of interchange of employees and staff etween manufacturers and supply undertakings would be of value to both sections of the industry. In his opinion, there is a direct obligation in the ndustry to bear the cost of post-graduate training by providing salaries which would be sufficient to encourage young men showing the necessary ability and energy to continue the widening of their experience beyond the normal period of their training. If this were adopted, the industry would benefit largely.

MR. WOODHOUSE then turned to another topic. Electricity is at the present time the cheapest form of illuminant. Its use, therefore, for lighting purposes is increasing at a rate never before equalled in the history of the industry. An important problem that has only been partially solved hitherto is the reduction in the costs of distribution to the average consumer. In general the cost of distribution adds 300 per cent. to the costs of production. It is interesting to note that the somewhat analogous case of distributing milk from house to house adds only 100 per cent. to the wholesale price. It is not generally realised that if the cost of fuel were halved, the reduction in the price of electricity would be trifling. Unfair comparisons are often made between Great Britain and other countries where the methods of transport are not so developed. For example, the carriage of coal from South Wales to London in order to generate electricity is more economical than transmitting the electricity by overhead wires from the coalfield. Mr. Woodhouse pointed out that the electrical industry, like all other human organisations, is changing, but that this is necessary if progress is to be made. He asked the younger engineers to continue that spirit of adventurous research which characterised the early pioneers.

THE American Institute of Sacred Literature—"an organisation for the promotion of popular study of the Bible and religion"—is inviting the co-operation of scientific workers and others in its efforts, and has produced a number of pamphlets written by leading men of science on the religious aspect of their work. We have before us an interesting little pamphlet by Prof. Edwin B. Frost, director of the Yerkes Observatory, entitled "The Heavens are Telling." Prof. Frost begins by stating and illustrating the enormous span of the material universe, the immense number of luminous objects which it contains, and the vast reaches of time required for their development, which must give to all who consider them a new and larger idea of the Cause behind them. After dealing with the exceedingly minute atoms and electrons which obey laws as definite and unvarying as the immense systems of the stars, Prof. Frost directs attention to the unity of the universe, as illustrated by the similarity of matter in the heavens and on the earth. This line of thought suggests that the combination of spirit and material body such as we possess may not be of great variety, and that we may not be vastly dissimilar from beings which may inhabit other planets circling around their appointed suns. Prof. Frost deplores the slow social development on the earth, particularly with respect to the evils of war, and considers that, from the planetary point of view, the most thorough application of the principles of Christianity seems to be the only way to bring our planet up to the moral standard to be expected of it. He contends that the scientific study of the material world tends to make spiritual conceptions less material, and divorces spirit from the material notions of mass, space, and time.

THE Christmas Lectures at the Royal Institution this year are to be delivered by Mr. Frank Balfour Browne, lecturer in zoology (entomology) in the University of Cambridge, the subject being "Concerning the Habits of Insects."

THE arrival of the German-built Zeppelin at Lakehurst, N.J., coinciding with the successful voyage to the Pacific coast and back of the airship *Shenandoah*, described in NATURE of March 1, p. 313, seems to have given a fresh impetus to American enthusiasm for the rigid airship. According to the *Engineer*, plans are now under discussion for the building of a series of these vessels, but of dimensions considerably in excess of any design so far evolved. Immediately on passing into American possession, the German Zeppelin, officially designated ZR3, was emptied of

the hydrogen with which she had been charged for the Transatlantic voyage, and had her gas cells refilled with helium. This is in accordance with the official American policy of forbidding the use of hydrogen in lighter-than-air craft under Government control. From a statement by Dr. R. B. Moore, former Chief Chemist of the United States Bureau of Mines, there is now in the United States a reserve of helium sufficient to keep filled and ready for service 200 airships of the capacity of the *Shenandoah*.

THE Fuel Research Board of the Department of Scientific and Industrial Research has for some time past been engaged in a general survey of the coal seams in all the coalfields of Great Britain with the object of classifying these according to their chemical and physical characteristics, and thus affording to the consumers valuable information as to the purposes for which each coal seam or each portion of a coal seam would be best suited. The first step in this direction was taken in the Lancashire and Cheshire Coalfield in co-operation with the local Coal Research Association, and the first result of this work has just been published in the form of a detailed report (London: H.M. Stationery Office, 2*s*. 6*d*. net) upon the Arley Seam of the Lancashire Coalfield. A good deal of useful information has been collected, the greater part of which was no doubt already in existence and available for those who knew where to find it, but it is a decided convenience to have the whole of this summarised and available in a compact and readily accessible form. There are a large number of illustrations, all of which, except the very useful map which forms the frontispiece, are photographs of coke produced under different conditions. It would be too much to say that these are useless and devoid of interest, but it is certain that the information which they convey is by no means commensurate with the expense of their production. It would have been better to have omitted these ten plates and to have published the pamphlet at a correspondingly lower price

MR. J. ELLIS BARKER, in the course of a further letter, writes as follows: "In your issue of the 1st November I protested that your reviewer, in dealing with my book, 'Cancer: How it is caused, How it can be prevented,' condemned my book on the basis of a number of serious mis-statements of his and of misrepresentations of my views which I enumerated. In a note appended to my letter your reviewer, instead of dealing with my arguments, describes my justified protest as a 'hymn of hate.' As he did not deal with my charge of mis-statement and mis-quotation, I imagine that your readers will draw their own conclusions." We agree with Mr. Barker that readers of NATURE, having read the review of Mr. Barker's book in our issue of October 4, p. 496, and also the correspondence on the subject which followed, may draw their own conclusions, and we are content to leave the matter thus.

DR. CHARLES SINGER, lecturer on the history of medicine at University College, London, is to deliver the Fitzpatrick Lectures of the Royal College of Physicians, London, on November 11 and 12. Dr. Singer will take as his subject "The History of Anatomy."

AN Economic Botanist with an academic knowledg of botany, and practical experience of plant breedin including paddy breeding, is required by the Gover ment of Madras. Particulars may be had from th Secretary to the High Commissioner for India, 4 Grosvenor Gardens, S.W.1. The latest date for th receipt of applications for the appointment i November 15.

A PRIZE of 300*l*. is offered by the Committee o the Christie Hospital, Manchester, for research o cancer. The object is to support research wor already in progress, and the competition is open t workers of any nationality qualified in medicine o in science cognate to medicine, but all papers sub mitted must be in the English language. Application must be received by the chairman of the Medica Board of the hospital on or before December 31.

A NUMBER of scientific works from the library o the late Sir William Crookes will be offered for sal by auction by Messrs. Hodgson and Co., 115 Chancery Lane, W.C.2, on Friday next, November 14, a 1 o'clock. The items include sets of the Chemica Society's Journal, *The Analyst*, the Journal of the Franklin Institute, the Journal of the Society o Chemical Industry, Phil. Trans. of the Royal Society 1863–1918, Catalogue of Scientific Papers (Roya Society), *Comptes rendus* of the Paris Academy o Sciences, 1864–1924, Revue Générale des Sciences, 1890–1924, etc. Catalogues are obtainable from the auctioneers.

AT the statutory meeting of the Royal Society of Edinburgh held on October 27, the following Officers and Council were elected: *President*, Sir James Alfred Ewing; *Vice-Presidents*, Principal J. C. Irvine, The Rt. Hon. Lord Salvesen, Prof. J. H. Ashworth, Prof. T. H. Beare, Dr. W. B. Blaikie, Sir Robert Blyth Greig; *General Secretary*, Prof. R. A. Sampson; *Secretaries to Ordinary Meetings*, Dr. Alexander Lauder, Prof. W. Wright Smith; *Treasurer*, Dr. James Currie; *Curator of Library and Museum*, Dr. A. Crichton Mitchell; *Councillors*, Prof. T. H. Bryce, Prof. J. Y. Simpson, Prof. D'Arcy W. Thompson, Sir James Walker, Prof. E. T. Whittaker, Prof. Henry Briggs, Mr. W. L. Calderwood, Prof. T. J. Jehu, Prof. C. G. Barkla, Prof. J. Graham Kerr, Lt.-Col. A. G. M'Kendrick, Mr. James Watt.

AT a General Meeting of the University of Durham Philosophical Society held on October 30 the following officers were elected:—*President*, the Chancellor of the University; *Vice-Presidents*, Sir Charles A. Parsons, Sir Theodore Morison, Prof. T. H. Havelock, Mr. Wilfred Hall, Prof. A. S. Ferguson, Dr. B. Millard Griffiths; *Secretaries*, Mr. J. W. Bullerwell and Dr. Grace C. Leitch; *Editor*, Dr. G. W. Todd; *Librarian*, Dr. F. Bradshaw; *Chairmen of Sections*, Mr. R. G. Lunnon (Chemical and Physical), Dr. Hickling (Geological and Biological), Mr. J. L. Burchnall (Mathematical), Dr. J. Wight Duff (Archæological), Mr. F. H. Alexander (Applied Science), Dr. A. Robinson (Philosophy); *Committee*, Dr. H. V. A. Briscoe, Commander Hawkes, Mr. S. H. Collins, Dr. G. R. Goldsbrough, Dr. J. A. Smythe, Mr. E. R. Thomas.

THE Gilbert White Fellowship has recently received a gift from the Earl of Dartmouth, four volumes of Journal for the years 1788, 1789, 1793, and 1794, with S. entries by the second Lord Dartmouth (1731–801) and some contemporary newspaper cuttings serted. The entries are in diary form and mainly eteorological and horticultural, with some records of lants, birds, and insect life. The localities from hich the observations date are Albury, Weymouth, astlehill, Whatcomb, Encombe, Carne, Henbury, ortland Place (London), Hayes (Kent), Maidenhead ridge, Tunbridge Wells, Walton-on-Thames, Brightelmstone (Brighton), Aylesford, and Grosvenor quare (London). About three-fourths of the entries re from Hayes, Kent. The association with Gilbert hite and his "Natural History of Selborne" is that is "Naturalist's Journal" was drawn up and has preface by White's correspondent, the Hon. Daines arrington.

IN the present year there occurs the tercentenary of he "Arithmetica Logarithmica," the first great work f Henry Briggs; the friend and coadjutor of Napier, nd the computer of the first table of common logaithms. In many senses the day of logarithmic tables to 4, 5, 6, or 7 figures is past. Where much computing has to be done, logarithms to a few figures are rarely used; what are used, and are often badly needed, are logarithms to 10, 15, or 20 figures. Recently the French have proposed to issue a 14 figure table and the Germans a 15 figure table. To celebrate worthily the tercentenary of Briggs's achievement, the Biometric Laboratory of University College, London, has arranged to issue "Logarithmetica Britannica," a standard table of logarithms of the 90000 integers of five digits, to 20 places of decimals. The necessary calculations are being undertaken by an able and enthusiastic computer, Mr. A. J. Thompson, of the General Register Office, Somerset House. It is to be published in nine parts by the Cambridge University Press, at the rate of about two parts a year, the first section (Part ix.) giving logarithms of integers from 90000 to 99999, together with their second and fourth differences, being now in the press. The success of the undertaking, which is not an enterprise of profit, can only be assured if a large section of the mathematical world shows readiness to commemorate with the producers of this work the tercentenary of the "Arithmetica Logarithmica."

Our Astronomical Column.

THE NOVEMBER METEORS.—Mr. W. F. Denning writes that this display may be expected to recur on he morning of November 15, but that it is not likely o be an abundant one. Meteors are evidently disributed along all parts of the elliptical stream, for ome of them are visible every year at mid-November. Occasionally there is quite a noteworthy shower, hough the parent comet (1866 I. Tempel) may be ear aphelion. The radiant point of the shower eing situated in the "sickle" of Leo, which does not ise until about 10.15 P.M., the meteors are invisible n the early hours of the evening. This year moonight will somewhat interfere with observation and overpower the fainter meteors. On clear evenings etween November 17 and 21, some of the Andromedids f Biela's comet may probably be seen.

A REMARKABLE PLANETARY NEBULA IN CASSIOPEIA.—Mr. J. H. Reynolds contributes an article to the *Observatory* for October on the nebula N.G.C. 7635, which was noted by Sir W. Herschel as containing an 8th magnitude star eccentrically placed. The article is illustrated by a photograph taken at Mt. Wilson by Prof. E. Hubble. It shows a slightly flattened ring 2′ 40″ by 2′ 15″, the interior of which is dark except for the southern third of its area, where it is strongly luminous. There is also some faint nebulous light outside the ring.

The star in the centre of the ring is very faint, about mag. 17; the star of mag. 8 mentioned above is about three-sevenths of the distance from centre to circumference. Its spectrum has been photographed at Mt. Wilson, being of type intermediate between O5 and the Wolf-Rayet stars. This spectrum makes the actual association of the star with the nebula more probable. Mr. Reynolds suggests that the illumination of the nebula may be due to its radiation, though its eccentric position is against its being the parent star of the nebula. He notes that if we assume the distance of the nebula as 20 parsecs (almost certainly a minimum estimate) its diameter is some 3000 astronomical units. (By an error, 9000 is given in the article.) He looks on these gas shells as marking the place of former novæ, and thinks that their duration is probably short.

MINOR PLANETS.—It seems most likely that the interesting object discovered by Dr. Baade on October 23 is a planet; its aspect is quite stellar, and its motion could be represented by an orbit not unlike that of Eros. Photographs were obtained at Greenwich on October 28 and 30, the magnitude being about 9·0. The arc of observation is still too short to deduce a trustworthy ellipse, but it appears that perihelion was passed about a month before discovery, and that the perihelion distance is somewhat less than that of Eros, which is 1·14. Prof. Kobold has computed the following parabolic orbit, presumably not with the idea that it is the real form of orbit, but in order to represent the motion for the next few weeks. On October 30 his computed place was right in declination, but 10 sec. too small in R.A.

$T = 1924$ Oct. 2·592 G.M.T.
$\omega = 134^\circ\ 17'$
$\Omega = 210\ \ 55$ } 1924·0
$i = 32\ \ 7$
$\log q = 0{\cdot}12463$.

EPHEMERIS FOR MIDNIGHT.

	R.A.	N. Decl.
Nov. 7	$22^h\ 17^m\ 24^s$	$5^\circ\ 59'$
11	22 35 0	3 53
15	22 52 0	2 3
19	23 8 28	0 32

The last two places have been deduced by extrapolation.

The motion is through Pegasus and Pisces. The meridian passage remains nearly stationary at about $7^h\ 15^m$, so that the object will be observable for some time.

Mr. B. M. Peek, while observing Nova Persei on October 27, detected a faint object very near it, which proved to be a minor planet. He communicated with Dr. W. H. Steavenson, who was able to observe it on the following night. If it had been new, it would have been the first visual discovery for many years, but Mr. G. Merton has established its identity with No. 709.

Research Items.

CEREMONIAL EXCHANGE IN EASTERN MELANESIA.—M. Raymond Lenoir, who has made a special study of the institution of north-west America termed, in his opinion improperly, *potlatch*, has published in *L'Anthropologie*, T. xxxiv. No. 5, an examination of the system of ceremonial exchange in the trobriands described by Dr. B. Malinowski in his "Argonauts of the Western Pacific," in the light of conclusions derived from a consideration of the evidence relating to similar customs not only from America, but also from the Asiatic Eskimo, the Chukchees, and the Melanesians of Bismarck Archipelago and the Solomons. Dr. Malinowski found that sea voyages, entailing a long and expensive communal preparation in accordance with a certain ritual, were undertaken with a view to the exchange of certain objects of wealth which were passed on by the recipients from island to island in an endless chain. This ceremonial he regarded as a phase of primitive economics. M. Lenoir, however, regards it as an institution which has grown out of a state of war, of which it is an attenuated form, and intended to preserve the relative status of different social groups. The maritime expedition is a raid in which the booty carried off by the victors or the gift received by them at the making of peace is represented by the ceremonial exchange of these objects. The conception of status applies to both forms of ceremonial exchange described by Dr. Malinowski, and the economic conception is accordingly a secondary or later development.

THE PRE-INCA AND INCA CULTURE OF PERU.—From 1899 until 1901, Dr. Max Uhle was commissioned by Mrs. Phoebe Hearst to conduct archæological excavations in Peru on behalf of the University of California, but owing to a variety of causes, no report on the excavations has been published. It has now been decided by the University to issue descriptions of the collections made by Dr. Uhle. The first of these has just been published as one of the Publications in American Archæology and Ethnology of the University. In it Messrs. A. L. Kroeber and W. D. Strong describe the collections from Chincha. The Chincha Valley was a peculiarly favourable site for archæological study as the Chincha Indians were one of the strongest and most famous tribes of Peru, and before the Incas became supreme, threatened to conquer all the interior of Southern Peru. Excavations were carried out at six main points in the Valley. The most important evidence which they produced, from the point of view of the sequence of culture and chronology, was the pottery; but the conclusions to which this points are supported by the other antiquities. These included shells and beads, textile apparatus and textiles, and objects of metal, as well as human remains. The cultural periods distinguishable are Inca, with which were associated beads of blue glass of European origin, and possibly two pre-Inca periods, Late Chincha I. and Late Chincha II., the latter being perhaps a phase of transition with which the Inca overlaps. There are also some indications of a proto-Chincha period in the form of objects of shell and ivory as well as fragments of pottery which suggest the Nasca or proto-Nasca style. The chronology suggested is for the Inca period *c.* 1425, for Late Chincha II. about a century earlier, and for Late Chincha I. from about 1000 or 1100.

THE GOAL OF COMMERCE.—Mr. G. G. Chisholm, in the Herbertson memorial lecture, published in the summer issue of the *Geographical Teacher*, says that the goal of commerce "is that stage in the evolution of commerce when the inhabitants of the earth wi be able to enjoy the greatest possible variety c commodities supplied at the least cost and with th greatest attainable stability of prices." This is definition with which few will wish to quarrel. Ther may be dissentients, however, when Mr. Chisholr goes on to say that the only condition of reachin that goal on which it is necessary to lay stress i the completion of all the main lines required in th network of communications. In fact, he himsel proceeds to point out that there are other importan factors besides lack of communications which stan in the way that leads to this goal. He instances th excessive density of population in Far Eastern regions The low wages arising from over-population in certai lands react, he points out, on industries in othe countries by bringing about excessive competition o one hand, as in the case of India and Lancashire in th cotton trade, and on the other, by restricting the pur chasing power of the people and therefore the marke which those lands might afford. After many reference to writings on the subject of over-population, Mr Chisholm contributes the suggestion that the bes solution of the problem of how to reach the goa of commerce is "to raise the standard among th poorer classes of the coloured peoples as quickly a possible to the level of the whites, so far as that ca be done." He does not develop his suggestion o touch on the problem as to how the increase o wages of the peoples, who at present have a lo standard of living according to Western ideas, ca be prevented from leading to a serious rise in th price of raw materials (such as cotton, jute, rubber and of foodstuffs (such as oil-seeds, coffee, cocoa tea, and so forth), as to lower appreciably the standard of living of the peoples of the industrial regions o the world. In an article in the *Times* of October 1 attention is directed to the enormous increase of th consumption of wheaten flour in the Far East. Vancouver, which exported only about half a million bushels of wheat in the year ending March 1921, exported forty-one and a half million bushels in the year ending March 1924! This went mainly to Japan and China. At the same time the price of wheat in Great Britain, which rarely before the War exceeded 35*s.* per quarter, has this month risen to more than 70*s.*! This article affords a very interesting comment on the problem in question.

TSETSE-FLY INVESTIGATIONS IN NIGERIA.—The *Bulletin of Entomological Research*, vol. xv., August 1924, contains a paper by Drs. L. Lloyd, W. B. Johnston, W. A. Young, and H. Morrison, on tsetse-fly investigations in the northern provinces of Nigeria. This work contains a record of the trypanosome infections, food, and breeding of *Glossina morsitans* and *G. tachinoides*, obtained by examining these flies at various foci over a period of fourteen months. It confirms the fact that the breeding of both species is practically confined to the dry season, and follows a period of increased food supply. The tsetse-fly, *Glossina morsitans*, does not feed on reptilian blood, but in times of hunger draws some of its food from birds: in the locality under consideration it resorts mainly to small antelope, big game being scarce. *G. tachinoides* is less restricted in its diet, and in the wet season one-fifth of its food was drawn from a group of animals which included man, monkey, and dog. The infection of the flies with *Trypanosoma vivax* and *T. congolense* bears a close relation to the amount of blood obtained from antelope, and consequently *G. morsitans* is in general nearly four times as heavily infected as *G. tachinoides*. Infections with

T. brucei and *T. gambiense* are scarce in this locality. Trypanosome infection rises just before the main breeding season in *G. morsitans* in all localities, and in *G. tachinoides* in places where the fly is largely a nimmal feeder. The proportional infection in general falls in the season of most rapid breeding, owing to the masking of the actual rise by the number of young flies examined. It rises rapidly when breeding ceases. The total infection is reduced when fly-food is hard to obtain, in the time of long grass and flood, owing to *T. vivax* infections dying out when the flies are starved. There is just an indication that postponement of grass burning may interfere with the free breeding of *G. morsitans*, and in some cases that of *G. tachinoides*. This possibility is to be tested. The experiment of excluding game and fly from one of the dry season foci of the flies by means of fencing will be carried out.

DISTINCTION OF THE TWO DRUGS, *HELLEBORUS NIGER* AND *H. VIRIDIS*.—Mr. T. E. Wallis and Miss Alison M. Saunders have carried out a useful if somewhat negative service to pharmaceutical knowledge by their careful anatomical investigation of the rhizomes and roots of *Helleborus niger* L. and *H. viridis*, upon which they report in *The Pharmaceutical Journal and Pharmacist* for July 26, 1924. These parts of both plants are employed as drugs, and various writers have described anatomical criteria in these organs by which the two species may be distinguished. The result of thorough examination of a wide range of specimens is to negative the validity of all such suggestions, and the authors recall an earlier suggestion of Hartwich that the rhizomes should be collected with the basal leaves attached, as these are trustworthy means of determining the two species.

A MILDEW DISEASE OF THE "WILD HOP."—A brief note by Messrs. E. S. Salmon and W. M. Ware in the *Gardeners' Chronicle* for October 18 records the finding of *Peronoplasmopora humuli* on "wild" hops in the hedgerows of Kent and Middlesex. Until now this fungus, first described by Japanese workers as occurring in that country, has been little noticed in Great Britain, since it was found by the writers on cultivated hops in the Experimental Hop Garden at Wye in 1920, when it was assumed to be an introduction from America or Japan, introduced with the hop plants. This is still perhaps the explanation of its occurrence here, as if it had been long at home upon the "wild" hop of the south of England, itself usually an escape from the hop of cultivation, it would surely have more frequently been reported from the cultivated hop-field. Messrs. Salmon and Ware note its striking resemblance to the mildew on nettle, *Peronospora urticæ*, and are apparently engaged in further investigation before deciding that these two mildews are not the same species.

A LOWER CRETACEOUS FERN.—Prof. Seward describes an exceptionally well-preserved specimen of the genus Tempskya, a fern characteristic of certain Lower Cretaceous Floras, in the *Annals of Botany*, Vol. 38, No. 151, July 1924. He names the specimen provisionally *T. Knowltoni* (anatomical characters of stem, root, and petiole alone scarcely providing the material for a final placing of the plant), after Dr. F. H. Knowlton of the U.S. Geological Survey, from whom he received the specimen and who reports that its probable source is the Kootanie formation of Montana. Tempskya was a fern of somewhat unusual habit, a mass of slender dichotomously branching stems, some of the branches bearing thickly clustered petioles, and all growing within a thick tangle of interlacing roots, forming together a kind of "false stem," which as a whole in some cases had a definitely dorsi-ventral habit. The stem contains a solenostelic vascular system, and Prof. Seward concludes that the examination of the present specimen supports his previous decision, based on material examined earlier, that this fossil fern has affinities with the modern Schizeaceæ.

JURASSIC AMMONITES OF INDIA.—Dr. L. F. Spath (*Palæont. Indica*, N.S., ix., No. 1, 1924) gives a revision of the ammonites from Kachh based on the collection of J. F. Blake, now in the British Museum, and introduces many new generic names. The species are mainly of Upper Jurassic age, ranging from Callovian to Kimeridgian, but a few are referred to the Aptian. The author considers that the widespread simplification of suture-lines in post-Triassic ammonites has not been fully appreciated, and suggests that the natural order of Jurassic ammonites may well be from complex to simple. The "families" considered are regarded as morphological rather than genetic units, and their relationship to the long-lived and fundamental families Phylloceratidæ and Lytoceratidæ will be considered later.

ROSE QUARTZ.—The cause of the colour in rose quartz has been very thoroughly investigated by E. F. Holden, and his conclusions are published in the *American Mineralogist*, vol. 9, April and May, 1924. Rose quartz is always massive. Occasionally pink crystals occur, but their colour is due to the presence of hæmatite inclusions. The effect of radium radiations on white or rose quartz is invariably to produce a dark smoky colour, and it is interesting to notice that smoky quartz is a constant associate of radioactive minerals in Madagascar and Ontario, whereas rose quartz is not. Careful analyses show that the rose colour cannot be due to titanium or iron, which are in all cases accounted for by the presence of rutile inclusions and limonitic stains respectively. Manganese, however, varies regularly with the depth of the tint; the absorption spectrum agrees with that of trivalent manganese glasses and solutions; and the pleochroism is exactly like that of other minerals which owe their colour to the presence of trivalent manganese compounds. The colour can, moreover, be closely imitated by dissolving less than 0·01 per cent. of manganese in a silica gel, and in this case, as in actual rose quartz, the colour disappears on heating to the transition temperature of 575° C. The convergence of evidence is therefore completely in favour of the conclusion that rose quartz owes its tint to the presence of trivalent manganese. In a former paper (*Am. Min.*, vol. 8, July 1923) the same author showed that the colour of citrine, like that of colloidal solutions of ferric hydrate, is due to sub-microscopic particles of hydrous ferric oxide.

THE VAPOUR PRESSURE OF CARBON AT HIGH TEMPERATURES.—In an investigation of the carbon arc light, Messrs. H. Kohn and M. Guckel have measured photometrically the brightness of the crater surface, using different kinds of nearly pure carbons and graphite, with different currents, and pressures varying from 5 to 0·06 atmospheres, the gases employed being air, argon, nitrogen, and carbon dioxide (*Zeitschrift für Physik*, September 17). Above a certain input the surface brightness, and therefore the temperature of the positive crater, reaches a maximum value, which does not increase with increase of current; this constancy has been observed at atmospheric pressure, from 0·3 to 2·1 amp. per sq. mm.

The maximum temperature was the same at the same pressure for the different carbons, and the different gases in which they were used. The ionisation in the arc, on the other hand, depended on the gas; the difference between the anode fall in air and argon was about 50 per cent. The equilibrium temperature of the crater is thus independent of the chemical and electrical processes in the arc, and probably depends, as Lummer has already indicated, on a thermodynamical equilibrium, the evaporation equilibrium of carbon. The pressure equilibrium-temperature curves are identical over the whole range for all four gases; from 5 to 0·8 atmospheres they can be represented by the Clausius Clapeyron equation, and so can be regarded as the vapour pressure curves of carbon, confirming the preliminary results of Fajans and of Kohn. The probable value of the heat of vaporisation of graphite, at room temperature, is deduced as $\lambda = 139{\cdot}2$ k. cal.; this value may be 7 per cent. too high or too low. The value deduced from the theoretical chemical constants, assuming the vapour to be monatomic, is 141·4.

THE EFFECT OF OXIDISERS ON SENSITIVENESS AND ON THE DEVELOPABLE IMAGE.—In the October number of the Journal of the Franklin Institute is a communication on this subject by Messrs. S. E. Sheppard, E. P. Wightman, and A. P. H. Trivelli, of the Eastman Kodak Company. After a concise summary of the results of recent work, the authors say that it appears from these and other facts that the development centres are latent image spots "which apparently consist of colloidal silver, and that these in turn proceed from pre-exposure sensitive spots in the grain, which may also consist of silver specks, possibly only a few atoms in magnitude." Previous work has shown that the treatment of an ordinary plate with copper sulphate solution merely lowered the sensitiveness of the plate, shifting the H. and D. curve to the right. But the authors find that if the emulsion is diluted so that there is only one layer of silver-salt grains, the copper sulphate treatment causes a marked increase of the steepness of the H. and D. curve, the maximum density being little if at all affected. This matter is being further investigated. When plates are treated with chromic acid the sensitiveness is rapidly reduced and gradually approaches a constant value. The authors have tried the effect of chromic acid on the developable image, and find that it is very considerably destroyed, the slope of the H. and D. curve is much reduced, but that after even many hours' treatment, the last traces of the developable image are not removed. Permanganate appears to be more active in its destruction of sensitiveness than chromic acid, and the authors are investigating its action on sensitiveness and on the developable image.

RESEARCH ON INDIAN TIMBERS.—An account of the research work being carried out on Indian timbers at the Forest Research Institute, Dehra Dun, India, appears in the *Chemical Age* for October 11, 1924. The most important section of the work deals with timber seasoning, experimental kilns with complete mechanical equipment having recently been erected. Wood preservation is also receiving attention; several of the Indian railway companies are installing plants for treating sleepers. Sleepers treated with the oil Avenarius Carbolineum have been found to show no signs of decay after being in the ground for two years. During the past year, 11,000 timber tests have been carried out. An experimental paper-pulp plant is now working, and an exhaustive inquiry into the tan-stuffs of the mangrove forests (Lower Burma) h just been completed.

THERMAL ACTIVATION BY COLLISION.—In the Jou nal of the Chemical Society for September, Hinsh wood and Hughes describe experiments on the therm decomposition of chlorine monoxide. The reacti appears to be complicated by intermediate produc but an average value of the velocity constant w found. From this the number of molecules reacti per second is calculated. The ratio of this to t number entering into collision per second (in bo cases per c.c.) gives the fraction of effective collisio Pfaundler (whose name does not appear to be me tioned) about forty years ago suggested that on collisions between molecules having a certain exce of energy above the mean value are effective, ar if Q is the excess energy, Maxwell's result sho that the ratio mentioned can be equated to $e^{-Q/R}$ The value of Q is found to be 22,000 cal. E plotting log $(1/t)$, where t is the time for a give fractional decomposition, against 1/T, a value of th "heat of activation" is found in the usual way t be 21,000 cal., and the conclusion is reached that th agreement seems "to render it certain that bimol cular reactions can be interpreted in terms of simp thermal activation by collision," without recourse t the radiation theory.

DESTRUCTIVE DISTILLATION OF COAL.—The Journa of the Royal Society of Arts for September 26 an October 3 and 10 contains a report of Cantor Lecture by Mr. E. V. Evans, chief chemist of the Sout Metropolitan Gas Company, on this subject. A give number of therms available as raw coal can be dis tributed among gas, tar and coke in a variety o ways, depending on the type of carbonisation pro cess adopted and the conditions of its operation. A diagram is given showing the distributions in hig temperature carbonisation and in low temperatur carbonisation. The yield of therms as gas in th former is more than double that in the latter, less ta is obtained, and less volatile matter is left in the cok as compared with low temperature carbonisation There is practically no difference between volatil therms and coke therms in the two processes if th volatile part in the coke is taken into account. Th difference is merely one of distribution. The rate o carbonisation is shown by diagrams. A very larg volume of gas of high calorific value is evolved in th first ten minutes after closing the door of the retort in this period 5 per cent. of the total gaseous therm is produced. In the second lecture the very clos relationship existing between gas and tar was fully considered. Laboratory experiments show that th total volatile therms (gas and tar) decrease gradually as the rate of carbonisation becomes slower, there being a very marked decrease in the case of exceedingly slow carbonisation, and the ratio of gas to tar therms decreases considerably with reduction in the rate of carbonisation. The results are interpreted by tar cracking. The belief that the rapid heating o coal is very wasteful of thermal energy is mistaken. The physical conditions obtaining in the retort were explained in the third lecture, which concluded with an account of a process for producing briquettes from a mixture of coal and coke. This is considered more promising for the manufacture of smokeless fuel than low temperature carbonisation. By mixing inert material such as coke with the original coal, a rapid rate of heat transmission is attained which results in enhanced yields of volatile therms. Such an innovation in the carbonising process opens up new possibilities in the development of the gas industry.

The International Union of Geodesy and Geophysics.

THE International Union of Geodesy and Geophysics held its second meeting at Madrid on October 1-8, at the invitation of the Spanish Government. Out of the twenty-seven countries which now belong to the Union, twenty-five were represented at Madrid, and the total number of delegates who attended amounted to one hundred and fifty.

The scientific work of the conference was carried on in the seven Sections into which the Union is divided, namely, Geodesy, Seismology, Meteorology, Terrestrial Magnetism, Oceanography, Volcanology, and Hydrology, and in each of these the time available was barely sufficient for the adequate discussion of all the reports and communications which were presented.

The Section of Geodesy commenced its meetings four days before the formal opening of the conference, and even then found the time at its disposal too short. Its meetings were very well attended, there being usually about fifty members present, and a large amount of very useful work was accomplished.

In each Section, reports were received of the work done in various countries during recent years, and especially since the last meeting of the Union in Rome in 1922; proposals sent in by the different national committees were discussed; and joint meetings were held with other Sections to investigate matters of common interest.

At the meeting in Rome the Swiss representatives had proposed that the Union should recommend the adoption by countries newly taking up geodetic work, or where new work admitted of it, of an international ellipsoid of reference. This gave rise to a very full and interesting discussion, and finally the executive committee's recommendation to employ in such cases Hayford's ellipsoid of 1909 was agreed to, although an alternative proposal to use an "arbitrary ellipsoid" differing but slightly from Hayford's obtained a considerable measure of support. The importance of carrying out geodetic work in the southern hemisphere, of such a standard that it could be used in the determination of the earth's figure, was strongly urged, and Australia was suggested as an area where such work could very advantageously be undertaken. A committee was appointed to take such steps as might be necessary to advance the completion of an arc of meridian from the Arctic Ocean to the Mediterranean.

In the Section of Seismology, a very instructive report on the recent Japanese earthquake was presented by the Japanese delegates, and was fully discussed. The Section decided to continue the publication of the International Seismological Summary at Oxford, and also of the seismological memoirs which are published from time to time at Strasbourg.

The Section of Meteorology re-elected Sir Napier Shaw as its president for another period. A number of interesting reports were received, and joint meetings were held with the Section of Oceanography on marine meteorology, and with the Section of Hydrology on their relative spheres of activity and on the measurement of rainfall data. The Section decided to continue investigations in the next few years into the physical conditions in the upper air, and to extend them to altitudes above those usually reached by "ballons-sonde"; also, to proceed with research on the subject of solar radiation.

The Section of Terrestrial Magnetism had a long programme which provided many useful discussions on the procedure of observatory work, the measurement and interpretation of records, and the design of instruments. The extension of magnetic surveys to areas not yet surveyed, and especially in high northern latitudes, was strongly advocated. In the next few years the Section decided to direct its attention to the international comparison of instruments, the magnetic and electrical characterisation of days, and to certain special investigations for which instruments will have to be designed.

Prof. Odon de Buén, of Madrid, was elected president of the Section of Oceanography in succession to the late Prince of Monaco. Much attention was given to echo-sounding, and also to tidal phenomena. In the latter subject, a joint meeting was held with the Section of Geodesy to discuss the subject of earth-tides. A committee was appointed to arrange for co-operation with the International Association for the Exploration of the Sea and the avoidance of duplication of effort.

The subject of the changes of level and of gradient in the vicinity of volcanoes was discussed at a joint meeting of the Sections of Volcanology and Seismology; and in the former the geothermal gradient and the thermal constants of rocks occupied the attention of the members at its meetings. The bureau of the Section is at present at the Vesuvius Observatory, but it is hoped that the University of Naples may offer it accommodation, which would be a more satisfactory arrangement.

The Section of Hydrology was formed only at the Rome meeting, so that much of its time was occupied with questions of organisation. A proposal that it should amalgamate with the Section of Meteorology was considered, but was not adopted. In the special work of the Section, a valuable report on the gauging of the Nile discharge was presented from Egypt; the statistical methods in use in Italy in such work were explained; and a very interesting report came from France, which dealt with the prevision of floods and with the estimation of hydro-electric potentialities. The extension of the Section's work to the phenomena of glaciers and the avoidance of encroaching on the work of existing organisations was considered and a satisfactory solution was reached.

At the final meeting, the invitation of the Republic of Czechoslovakia to hold the next meeting of the Union in Prague in 1927 was accepted. Col. H. G. Lyons was elected general secretary of the Union for a further period.

The Spanish Government extended the most ample hospitality to the delegates. The Chamber of Deputies, not being in use at the time, was available for the meetings. H.M. the King of Spain presided at the opening meeting, and later a reception was held at the palace by their Majesties the King and Queen, to which all the delegates were invited. The arrangements for the meeting and for the various visits to museums, scientific institutions, etc., which were made by the National Committee and were in the hands of Señor D. Cubillo and Señor D. Galbis, were extremely well planned and worked without the least hitch throughout. After the close of the meeting, many of the delegates availed themselves of the excursions which the committee had arranged to Andalusia and to the eastern provinces, where they were shown the scientific institutions and the objects of special interest at the various places.

The technical communications received by the Sections will be published by them in due course in their reports of the meeting.

Ecology of Moorland Plants.

OTTO STOCKER, of Bremerhaven, has a very interesting review of the recent work by Montfort and himself upon this problem in *Die Naturwissenschaften* for August 8. The problem is an old one. Plants of the heath and of moorland, such as Calluna and Erica, have a form and structure that suggested to some of the earlier workers, and notably to Schimper, that they must be adapted to reduce water-loss arising from transpiration. Schimper advocated this view in his classical book upon "Plant Geography," and, faced with the problem that moors are by no means dry places, influenced probably also by his earlier studies of the mangrove swamps bordering salt water lagoons, he escaped from the difficulty by the assumption that these moorland soils must be "physiologically dry." This view of the xerophytic character of moor vegetation has been handed on from text-book to text-book, although it is based almost entirely upon the appearance of the vegetation and is unsupported by experimental evidence, apart from certain American experiments which showed that extracts of bog soils were toxic to certain non-ericoid mesophytes under certain experimental conditions.

Now Montfort has shown by direct experiment that the water of moorland soils is not toxic to moorland plants, and he also concludes by the way in which these plants still release water from cut stems, or exude it in drops from the leaves (guttation), that the moorland water in no way diminishes the absorption of water by the root system or its active pumping upwards into the shoot. Furthermore, by measurements of transpiration as well as of water absorption, Montfort showed that these processes went on freely in all plants grown in normal moorland water, though some extracts of soils in which secondary decompositions were proceeding might prove toxic to plants and reduce water absorption and transpiration as well as every other normal activity of the plant.

"Physiological dryness" seems, then, to be a myth; under the examination of Stocker there is not much left of the case for the xerophytic character of Calluna and the ericoid shoot. It is true that the single leaf of the ericoid plant may be interpreted as xeromorphic in structure, but a calculation of the total leaf surface per unit of root system puts Calluna ahead of many mesophytes in its proportion of transpiration surface, and an examination of the amount of transpiration of the plant as compared with its root absorbing system shows Calluna to be better classed as a "xeromorphic mesophyte," able to lose water like a mesophyte because in its natural habitat plenty of water is practically always available. Stocker has his own teleological explanation to replace the one he has so decisively disposed of. He suggests that the special ericoid type of leaf has its advantage on the wind-swept moor as a type that prevents the marginal withering effect produced by drying winds.

It may be pointed out, however, that exactly the same criticism can be brought against this view of Stocker's that he levels against the view of Schimper, namely, that it lacks experimental basis. His next suggestion, that this type of vegetation dominates the moors because its high rate of transpiration enables it to accumulate large quantities of salts from the relatively dilute salt solution of the moor, certainly seems to rest upon a fundamental fallacy, which again has often crept into the text-books. The salts in the soil are not drawn in with a current of water rushing into open pipes and then concentrated by the evaporation of this solution at the leaf surface. The water itself enters, diffusing across a protoplasmic membrane in accordance with the osmotic gradient, and this condition determines the entry of water alone a not of the salts with it. If the salts enter, they their turn will diffuse inwards according to th relative concentration within and without the pla and therefore their rate of entry will only be indirec affected by the rate of transpiration, and this proc is not likely to influence greatly the amount of s collected in the plant.

This conclusion, the only one possible from physico-chemical point of view, has now an expe mental basis in the work of Muenscher (*Americ Journal of Botany*, vol. 9, pp. 311-329, 1922). Whil then, Stocker disposes effectually of the present tele logical explanation of the characteristic ericoid type leaf, he is not very happy in the similar type of explan tion that he puts forward himself. But it may be ask —is it necessary to put forward any theory of this ty to account for the characteristic heath and moorla vegetation? The writer has recently approached t subject from another point of view in two brief pape with Miss Hinchliff, published in the *Naturalist* (192 pp. 263-268, and 1924, pp. 201-209).

Dr. F. E. Clements, Associate in Ecology of t Carnegie Institution, has recently shown in his mon graph upon "Aeration and Air Content," published b the Carnegie Institution, that one of the governi factors in the peaty soil of the moorland and the heath the lack of proper aeration in this soil, which renders unsuitable for the growth of the root system of normal plant. The present writer has pointed o that the metabolism of the root system of differe plants may be expected to differ, and that some plan may require less oxygen for their growth; that t plants on peat are perhaps such plants, and tha associated with this peculiarity they have anothe namely, that they form unusually large quantities fat in the roots as they grow. These fatty substanc are then sent up into the shoot and accumulate fir at the surface of the shoot as an early and abnormall thick cuticle, and then within the shoot again in earl deposits of secondary endodermis and then of cor layers within that endodermis. It is pointed out tha these fatty deposits are responsible for certain stru tural changes, and a later paper (Beatrice Lee an J. H. Priestley, "The Structure, Occurrence an Distribution of the Cuticle," *Annals of Botany*, Jul 1924) has strengthened the conviction that a thic cuticle deposited at an early stage will profoundl modify the structure of the young shoot and of th leaves upon which it is deposited.

This developmental factor may in the end prove t have a great deal of influence upon the characteristi form and structure of the plants growing on the peat In this case their characteristic habit is not traced t an adaptation to control water loss, but is found t be a natural developmental consequence of the char acteristic metabolism of a root system growing in a soil that lacks sufficient aeration. Wherever the peat plants grow, whether in peat or in other soils, they will retain this characteristic metabolism, accumulate fats, and show the same characteristic structure But in peat soils they reign supreme because other plants which do not have this metabolism fail t grow there. One further interesting point about this view is the light it throws upon the unsuitability of many of these peat plants to soils that are rich in calcium, calcium salts producing very insoluble soaps with fatty acids, so that in a soil rich in calcium the fatty acids, instead of passing upwards to the shoot, accumulate in the root system and plug it up until its normal functions are carried out with difficulty.

J. H. PRIESTLEY.

High-Speed Tool Steel.

NEARLY a quarter of a century has elapsed since a revolution in metal-machining practice was used by the invention of the so-called high-speed tting tools by Messrs. Taylor and White, of the ethlehem Steel Company, U.S.A. This discovery as not an isolated one but was simply the last of a ries of connected discoveries leading to this parti- lar result. To a large extent it was empirical and advance of the metallurgical theories of the time. gave rise to various researches designed to explain ie remarkable properties of these steels. Most of ese have thrown some light on the properties in uestion, but none of them can be said to have provided complete explanation of all the phenomena observed. he paper, therefore, by Messrs. Marcus A. Grossmann nd Edgar C. Bain "On the Nature of High Speed teel," presented at the autumn meeting of the Iron nd Steel Institute, is to be welcomed in that it con- itutes a further attempt to place on a scientific undation a comprehensive theory of the mode of ction of these steels.

The paper gives an account of the physical pheno- ena occurring from the time of casting the homo- eneous melt to the production of the hardened ols. The authors emphasise the point that high- peed steel, far from being an alloy having wholly nique properties, merely possesses to an unusually harked degree certain of the tendencies which may lready be discerned in other steels and alloys. They ave availed themselves of the results of many of the ethods of investigation applicable to metals, and the nore recently developed conceptions of crystal struc- ure and hardness constitute the foundation upon which the views offered have been built. They onsider high-speed tool steel essentially as a binary lloy, of which one constituent is a solid solution of hromium in iron and the other the complex carbide ontaining tungsten, chromium, vanadium, and carbon. n the unhardened condition the finished bar is re- garded as containing on an average 30 per cent. of arbide, but this is not evenly distributed. Rather nore than half of it is in the form of fine particles which have been precipitated from solid solution, and, owing to "coring" in the original dendrites, it is never completely removed. There is a concentration gradient from the centres to the edges of the crystals. The remainder of the carbide is in comparatively coarse particles, which represent the plates of carbide in the original eutectic. These are still present in fairly pronounced streaks throughout the piece.

When this aggregate is heated to the hardening temperature (about 1300° C), the solubility of the carbide in the γ iron increases rapidly as the tempera- ture rises, so that at the highest temperature nearly half the total carbide can be dissolved in the matrix. Owing, however, to the sluggishness of diffusion of the alloying elements, especially the tungsten, the amount dissolved never reaches the theoretical figure, and the austenite formed is far from homogeneous. In addition, small regional concentration gradients are set up round the larger carbide particles, the solution of which is never complete. Incident- ally, the particles of excess carbide exercise a very useful function in preventing grain growth at this high temperature, which would otherwise be so rapid as to render the steel useless on account of brittleness.

After being suitably heated, the steel is now quenched, and in this process a portion of the austenite is transformed into martensite, so that freshly quenched high-speed steel shows under a microscope grains consisting of a mixture of austenite and marten- site, and distributed through them the excess carbide particles. A light etching reveals the austenite grains and the excess carbide particles, but suitable further etching shows the martensite quite clearly. The relative proportions of martensite and preserved austenite undoubtedly vary from place to place. The regions lower in carbide contain more martensite, while those richer in carbide contain more austenite.

A piece of freshly quenched steel is thus to be con- ceived as containing regions of austenite-martensite mixtures of widely varying stability. On heating at comparatively low temperatures, softening is con- sidered to take place in the martensitic areas, and this low-alloy martensite resembles carbon steel martensite. The decomposition of this can be traced both in changes of hardness and of shrinkage. On heating to 600° C. the phenomenon of secondary hardness is observed, due to the conversion of the austenite regions to martensite or troostite. This reaction takes place throughout the tool. The total effective hardening may be considered, therefore, as representing the algebraical sum of hardening effect of the transformation of the various austenites and the softening of the various martensites.

The authors do well to emphasise the point that "secondary hardness" is by no means restricted to high-speed steel and that it is not the same as "red hardness." The retention of austenite on quenching is characteristic of many alloy steels on heating to sufficiently high temperatures. When this is reheated at low temperatures, secondary hardening sets in owing to the formation of minute crystals of α iron and the precipitation of fine carbide particles. Indeed, it is likely that if the tungsten of high-speed steel were omitted altogether, the remaining elements alone would be sufficient to cause the retention of the aus- tenite and the appearance of secondary hardening. The special usefulness of high-speed steel, however, is due to the extent to which it exhibits the property of red hardness, and it is here that tungsten plays its rôle. The large, heavy, immobile atoms of this metal act by supporting the structure at these slightly elevated temperatures and prevent the diffusion and agglomeration of the carbide particles, which would otherwise take place with consequent softening.

H. C. H. C.

Isotopes and Spectra.

THE question of the spectroscopic evidence of the existence of isotopes, which has already been brought forward in our correspondence columns (see NATURE, March 29, May 31, August 16) is dealt with at length in two papers published in the *Japanese Journal of Physics*, vol. ii., Nos. 6-10,—the first by Nagaoka, Sugiura, and Mishima, on "The Fine Struc- ture of Mercury Lines and the Isotopes," and the second by Nagaoka and Sugiura, on "Spectroscopic Evidence of Isotopy."

The assumption is made that the mercury atom consists of a central mass with a proton quasi-elas- tically connected with it. Vibrations of this system are conceived to give rise to spectrum lines. Thus, several mercury lines are known to have large numbers of closely adjacent satellites. It is thought that these are due to coupled vibrations of the nucleus owing to the stimulus given by the principal line which seems to be excited by the change of electron configuration according to Bohr's scheme. A number of facts are

adduced in support of the hypothesis. It is possible to calculate the intervals between the lines which would be produced by the vibrations of such a nucleus. Knowing the masses of the main core and the proton, and taking these from the observed values of Aston for the isotopes of mercury, the calculated intervals are shown to be in good agreement with the intervals between the satellites of mercury lines. The latter were carefully measured by the use of crossed Lummer-Gehrcke plates, and a discussion is introduced on the forms of the interference points so produced. It is concluded that the fine structure of mercury lines is due to the existence of several isotopes.

In the second paper the more general hypothesis is advanced that non-series lines in spectra are produced in an essentially different manner from the series lines. The latter are adequately accounted for by the movements of satellite electrons, according to Bohr's model, but the non-series lines are assumed to arise from the vibrations of pairs of atoms coupled in the manner described above for the mercury nucleus and its associated proton. When an element has two or more isotopes, two kinds of coupling are possible—symmetric and asymmetric—corresponding to pairs of atoms having the same and different masses respectively. A formula is given for calculating the wave-length intervals between lines arising from the coupled atoms, and these are shown to be in good agreement with intervals found in the spectra of elements the isotopes of which are known.

The lines having these intervals are accordingly looked upon as products of atomic vibrations and not of passages of an electron from orbit to orbit. Most of the lines so explained are spark lines. They are remarkably numerous in the spectra of the monatomic gases; thus, more than 90 per cent. of the 856 neon lines given by Paschen are assigned to atomic vibrations, and in argon a still greater proportion. An explanation of this is given. It is concluded that atomic vibrations give rise to spectra having constant frequency differences, and the suggestion is made that unknown isotopes may be detected from spectroscopic data.

Problems of Unemployment Insurance.

AT the recent Toronto meeting of the British Association, a paper by Prof. John R. Commons, of the University of Wisconsin, on "The Limits of Unemployment Insurance," was read to the Section of Economic Science and Statistics. In view of recent discussion in Great Britain of the relative merits and demerits of insurance by industry, insurance by firms, and the present State system, a short account of this paper may be of interest.

Prof. Commons is a well-known advocate of unemployment insurance in the United States. Conditions in the States are, of course, very different from those prevailing in Britain, and in particular there is a strong prejudice against a State insurance scheme. Prof. Commons in his paper emphasised the point that the principle of overhead charges (*i.e.* those manufacturing costs that go on whatever the number of units produced) applies to labour just as much as to capital, though this fact is not generally realised by industrial firms.

The modern manufacturer is faced with problems of business cycles, overhead costs, and organised labour that were unknown to his predecessors of the time when Adam Smith wrote, or perhaps more correctly it would be truer to say that nowadays these problems are greatly intensified. Business cycles are "a normal abnormality of the nineteenth and twentieth centuries."

The business cycle results in a lag both in time and amplitude in the daily wages received by labour compared with the prices obtained for the product by the employers. Organised labour, however, tends to reduce this lag by boosting wages during the rise and holding them up during the slump. Consequently, such labour obtains a higher *daily* wage while employed, on account of the business cycle than would otherwise be the case.

Two solutions of the problem are apparent, either (1) the curve of employment or (2) that of daily wages must be smoothed out. If attention be concentrated on the first solution rather than on the second, the community of interest rather than the antagonism of interest between capital and labour becomes clearer.

Statistics, however, point to a curious paradox, for large firms show greater fluctuations in their labour demands than the smaller. This is not what might have been expected, since the large firm has presumably a much larger item of overhead relative to the number of employees, which would at first sight seem to intensify the inducement to make greater efforts to stabilise production, thus reducing the overhead costs per unit of product. Apparently in practice the large firms take care of their capital overhead by means of high profits at the peak and large reserves for the trough of the business cycle, compelling their employees to take care of the labour overhead on a slumping market. If the employment cycle is to be smoothed out, the principle indicated from this analysis is that industry should take care of both kinds of overhead. The only way, however, to induce industry to take care of this labour overhead charge is "through the pocket book."

Prof. Commons arrives ultimately at three propositions:

(1) The larger establishments should each carry, so far as possible, its own risk by way of setting aside its own reserve, not merged with the reserves of other establishments in a common fund.

(2) Establishments having a small number of employees should be treated differently from those with a larger number. They might, for example, be organised in the form of a mutual insurance scheme.

(3) Employees should not ordinarily be required to contribute to the fund out of their wages.

"It will be seen," concludes Prof. Commons, "that only from the largest establishments and not from the smaller establishments, nor from the employees nor from the State, can any material progress be made towards prevention of unemployment."

University and Educational Intelligence.

BELFAST.—Applications are invited for two posts in the Queen's University, namely, the professorship in bio-chemistry and the lectureship in bacteriology. Terms of the appointments are obtainable from the secretary of the college.

BRISTOL.—Prof. Andrew Robertson, professor of mining and mechanical engineering in the Merchant Venturers Technical College, has been appointed principal of the College in succession to the late Dr. Wertheimer.

CAMBRIDGE.—T. R. B. Sanders, Trinity College, has been elected to a fellowship at Corpus Christi College. A. M. Binnie, Queens' College, has been awarded the John Winbolt Prize in engineering. The number of freshmen who have matriculated this term is 1498. The corresponding figure in 1913 was 1110.

LEEDS.—The council of the University has appointed Dr. F. S. Fowweather to the lectureship in chemical pathology recently instituted. Dr. Fowweather graduated with First-Class Honours in chemistry (1st Division) at the University of Liverpool in 1914. Later he took up the study of medicine and graduated M.B., Ch.B., at Liverpool in 1922, afterwards obtaining the Diploma in Public Health (D.P.H.).

OXFORD.—Applications are invited by the Imperial Forestry Institute for a lectureship in tropical forest botany. Candidates must possess a thorough knowledge of tropical systematic and economic botany and ecology with special reference to forest vegetation. The latest date for the receipt of applications, which should be sent to the secretary of the institute, is February 15.

THE University of Manitoba is requiring a lecturer in zoology, to enter upon his duties at the beginning of next year. Applications for the post, together with particulars of candidates' published work, should be received not later than December 6 by the Secretary to the Board of Governors, University of Manitoba, Winnipeg, Canada.

APPLICATIONS are invited by the Denbighshire Education Authority for the principalship of the Acton Hall Technical Institute. Applicants must hold an honours degree in science, and a knowledge of mining is desirable. Applications, ten in number from each candidate, must be received by November 24 at the latest by the Secretary and Director of Education, Education Offices, Ruthin.

AT the annual convocation of the University of Bombay on August 19 the Chancellor, Sir Leslie Wilson, Governor of Bombay, delivered an address on "Democracy," in the course of which, enlarging on the dignity of labour, he observed that there is no reason why a graduate should not drive a plough or a motor-car. India's crying need to-day, he said, is not for Colleges of Arts but for scientific work and vocational training.

AT the time of writing, the following have been elected Parliamentary representatives of the universities of Great Britain and Northern Ireland:—CAMBRIDGE—Mr. J. F. P. Rawlinson (U.), Sir Geoffrey Butler (U.). COMBINED ENGLISH (Birmingham, Bristol, Durham, Leeds, Liverpool, Manchester, and Sheffield)—Sir Martin Conway (U.), Mr. H. A. L. Fisher (L.). LONDON—Dr. E. G. G. Little (Ind.). WALES—Mr. E. Evans (L.). QUEEN'S, BELFAST—Col. T. Sinclair (U.).

WE have mentioned in these columns the guide books and other pamphlets issued this year by the London County Council's Education Committee with the object of popularising the evening classes and other provision for adult education for Londoners. In this connexion it is interesting to note the causes to which the Buffalo Department of Education attributes the popularity of its adult education classes, which were in 1923 attended by one out of every fifteen persons in Buffalo over 16 years of age. These are as follows: Advertisement in newspapers, coloured posters, leaflets taken home by schoolchildren, announcements in motion picture theatres; personal invitations addressed to previous year's students; advisory committees elected by students to keep in constant touch with teachers in regard to subject-matter of courses, units of study and location and hour of classes; and special training for this work of teachers selected on account of their personality and their close acquaintance with the practical side of their subjects.

THE twenty-fifth annual general meeting of the Science Masters' Association is to be held under the presidency of Sir Berkeley Moynihan at the University of Leeds on January 5-7 and will consist largely of lectures and demonstrations by members of the University staff. According to the provisional programme which has been issued, there will be a reception by the Pro- and Vice-Chancellors of the University and Sir Berkeley Moynihan on the evening of January 5, after which the latter will deliver his presidential address. The second day of the meeting will be devoted to lectures and demonstrations, while on the last day there will be a joint discussion with the representatives of the University on the connexion between science teaching in schools and universities, followed by visits to works in the neighbourhood. An exhibition of books and apparatus will be open throughout the meeting. The railway companies are issuing return tickets for the meeting at the rate of a single fare and a third. The honorary secretaries of the Association are Mr. C. E. Sladden, Eton College, and Mr. W. J. Gale, Sloane School, Chelsea.

THE Universities Bureau of the British Empire, which among its many activities has already placed all interested in university education deeply in its debt by the annual production of the Yearbook of the Universities of the Empire, has increased the debt by a pamphlet giving the professional schools and post-graduation courses available in the universities and university colleges of Great Britain and Ireland. The universities are taken in order and under each are given particulars of correlated courses of study such as are generally referred to as "schools" and of specialist studies available at that institution. This is followed by a list of the various "schools"; under each entry is given the centres at which that particular subject can be studied. Finally, there is a list of subjects with the names of centres with which each is particularly associated, so that it is possible from the list to see at a glance where a subject receives special attention. The pamphlet is valuable for reference purposes and should also be extremely useful to colonial and foreign students desirous of pursuing their studies in Great Britain or Ireland. It can be obtained from the Bureau at 50 Russell Square, London, W.C.1.

FROM the Hokkaido Imperial University we have received a pamphlet consisting of replies to a *questionnaire* distributed last year by the League of Nations Committee on Intellectual Co-operation. It covers almost every phase of the university's history, its present condition and plans for the future. The schools of agriculture, forestry, fishery, and civil engineering have since 1918 been frequented increasingly by Chinese students, and some Americans have been attracted by the Fishery School and the entomological collections. In all these schools English has a conspicuous place in the curricula, but all lectures excepting those delivered by foreign teachers of foreign languages (English and German) are now delivered in Japanese. The university farms cover 1500 acres and the university forests more than 300,000. A considerable amount of university extension work is carried on in the form of lectures in scientific subjects for teachers and popular science lectures. The chief publication of the university is the Journal of the College of Agriculture, of which 160 exchange copies are distributed to universities and other institutions in foreign countries, including 65 in the United States, 14 in Great Britain and Ireland, 11 in Germany, and 10 in Australia.

Early Science at the Royal Society.

November 9, 1664. Sir Anthony Morgan promised to draw up a report concerning his majesty's power to give a grant of Chelsea College [Referring thereto, Oldenburg wrote: "Our council is now pressing to have an end of Chelsea College, which we doubt not will prove good; in which case Mr. Howard will be the society's gardiner, without admitting of any competitor, and Dr. Wilkins the weeder"].

1681. The Society was acquainted that Mr. Hodges was in a short time going to the East-Indies to reside at Haukly, upon the river Ganges; and that he was very ready to serve the Society in what he was able in that place.

November 11, 1663. Sir Robert Moray presented from prince Rupert to the Society an instrument of his highness's invention for casting any platform into perspective. It was ordered that the president, Dr. Wilkins [and others] wait upon the prince on the Friday following, and return him the humble thanks of the Society; and to shew him an instrument of Dr. Wren's invention for casting any natural object into perspective. Mr. Hooke suggesting that additions might be made to the invention, so that it might incline and recline, and be fitted to draw likewise solid bodies in perspective, and to describe all kinds of dials, was desired to bring in these additions. In the meantime it was ordered, that the prince's instrument should remain simple, as it was then, without any alteration thereon.—Sir Robert Moray mentioned a new use to be made of thermometers, viz., to know by their help the degrees of heat in a man's body in fevers, etc., by putting it into a man's hand, or mouth, or urine, etc. The physicians present conceived that there would be little certainty in it.

November 12, 1662. Dr. Charlton promised to provide a pike against the meeting for dinner, in order to show every sound tooth moveable.

1668. Mr. Oldenburg read a letter from Monsr. Huygens, in answer to what he had lately written to him by order of the Society, desiring him that if he did not think fit to print what he had discovered on the subject of motion, he would impart to them his theory of it, together with such experiments, as he grounded his theory upon. Monsr. Huygens' answer was, that he was ready to communicate to the society those rules and theorems, which he had found out in all the species of motion.

November 13, 1672. Mr. Locke being called upon for his sulphur-ball, which he promised at the last meeting to produce at this, excused himself, that he had forgot it, promising to bring it at the next.

November 14, 1666. Sir Robert Moray produced a loadstone digged up in England in Devonshire, brought from thence by the sons of Sir William Stroud for the king; which was committed to Mr. Hooke for the repository.

1678. Dr. King upon occasion of discoursing of pearls and bezoar-stones related, that he had often found pearls in the stomach of an oister; and conceived them to be generated as the bezoar-stones in the stomach of a goat.

November 15, 1682. There was a discourse with regard to great age. Mr. Hooke took notice of what Sir Christopher Wren had formerly acquainted the Society, that the people at Hudson's Bay commonly live to 120 or 130 years of age; and till that age are very lusty, and commonly go to hunting, which, when they are no longer able to do, they usually invite all their kindred, and lie down and resign themselves to be strangled by the eldest of those, who survive, and who takes the care of government in his father's stead.

Societies and Academies.

LONDON.

Royal Microscopical Society, October 15.—R. **Clay** and T. H. **Court**: The development of th Hooke microscope. After referring to the descri tion of Hooke's original instrument in his justl famous "Micrographia" (1665) and to the accour given by Sturm in his "Collegium Curiosum (1776) of his experiments with an English Hook microscope which had been lent to him, attentio was directed to the important improvement of th instrument due to Helvelius and described by hi in his "Machina Coelestis" (1673), namely, th screw fine-adjustment. All previous writers ascribe this addition to Marshal, whose celebrated instrumer is first described in Harris' "Lexicon Technicum (1704) (though it had almost certainly been cor structed and used so early as 1693). The failure c earlier writers to mention the important share whic Helvelius had in the development of the microscop is most probably due to the extreme rarity of th "Machina Coelestis."

PARIS.

Academy of Sciences, October 16.—M. Guillaum Bigourdan in the chair.—A. **Lacroix**: Short accoun of the second general meeting of the Internationa Geodesic and Geophysical Union, held at Madrid o October 1-8.—Charles **Rabut**: Scientific rules for th reinforcement of constructions in masonry.—Pau **Montel**: Complex families.—Maurice **Gevrey**: Certai linear integro-differential equations of the secon order.—André **Bloch**: A theorem of M. Borel an a generalisation of the Picard-Landau theory.— E. M. **Antoniadi**: Some changes recently observe on Mars with a telescope of 83 cm. aperture, a Meudon Observatory. These changes are shown o reproductions of eight drawings taken at differen dates.— — **Lyot**: The polarisation of the plane Jupiter.—R. **Dugas**: A system of points of variabl mass.—Louis de **Broglie**: A theorem of M. Bohr.— W. P. **Allis**: The damping of the oscillations of Hertzian resonator. The decrement of the fre oscillations of a resonator is the sum of two terms one of which corresponds to the Joule effect, th other, δ_H, to the radiation. It is shown experi mentally that δ_H is inversely proportional to th square of the wave-length.—C. **Marie** and G. **Lejeune** The influence of colloids on the cathode overvoltag of hydrogen and metals.—René **Audubert**: Photo voltaic phenomena. Details of experiments on th effect of light on the electromotive force of cells th electrodes of which consist of metals carrying a skin of another substance, such as copper oxide, coppe bromide, silver chloride, silver sulphide.—Henr **Lafuma**: The corresponding temperatures of solid bodies. Discussion of a recent communication by M. Brodsky on the same subject.—M. **Bourguel**: A general method for the preparation of true acetylenic hydrocarbons. The acetylene hydrocarbon ($R.C{\equiv}CH$) taken as a starting-point is converted into its sodium derivative (by sodium amide), methylated with methyl sulphate. The resulting hydrocarbon, $R.C{\equiv}C.CH_3$, by heating with sodium amide, is converted into the sodium derivative of the isomer $R.CH_2.C{\equiv}CNa$; this gives readily the hydrocarbon $R.CH_2.C{\equiv}CH$, the next higher homologue of the original $R.C{\equiv}CH$. The yields are high, and details of the application of the method to cyclohexylpropine are given.—E. **Caille** and E. **Viel**: Transformation of the iodostibinates of nitrogenous organic bases into crystallised iodomercurates.—de la

ondamine: The estimation of carbon monoxide in industrial gases. Comparative analyses with ammoniacal cuprous chloride, acid cuprous chloride, and the Damiens cuprous sulphate reagent.—Alfred Schoep: Dumontite, a new radioactive mineral. This new mineral is found as an enclosure in cavities of tobernite from the Belgian Congo. It is a hydrated lead uranyl phosphate.—G. **Rempp** and J. **Lacoste**: New study on the daily variation of the direction of the wind at Strasbourg.—Maurice **Lenoir**: The nucleus of the mother cell of the embryonic sac in *Fritillaria imperialis* observed during its prophasic evolution.—Mme. L. **Randoin** and H. **Simonnet**: The food equilibrium. Maintenance of the pigeon by means of a food regime entirely lacking the water soluble factor.—Charles **Henry**: The radiation of homeotherms and the calculation of nervous sensibilities.—Marcel **Duval**: The amount of sodium chloride in the blood of some marine invertebrates. Contrary to current views, the blood of certain marine invertebrates, particularly crustaceans, contains sodium chloride in slightly lower concentration than the external medium. As the blood and the surrounding sea-water are isotonic, it is probable that the deficiency in the osmotic pressure of the former is made up by the presence of organic substances.—Paul **Fleury**: The laws of action of saccase: influence of the reaction of the medium.—R. **Anthony** and Mlle. F. **Coupin**: A rhinencephalic convolution peculiar to certain carnivora: the *gyrus transversus areæ piriformis*.—E. **Hubault**: The presence of *Liponeura cinerascens* and of *L. brevirostris* in the upper valley of the Meurthe.

WASHINGTON.

National Academy of Sciences (Proc. Vol. 10, No. 8, August).—P. S. **Epstein**: On the simultaneous jumping of two electrons in Bohr's model. A new series in the arc spectrum of calcium ($1p - mp_1$), attributed to the simultaneous jumping of two electrons, has been discovered by H. N. Russell and F. S. Saunders. This condition can be accounted for on the principle of correspondence provided that there is coupling of electrons within the atom.—J. A. **Becker**: The Compton and Duane effects. The two effects may be distinct and their appearance or non-appearance may depend on the intensity of radiation. Using an aluminium crystal as the secondary radiator, the Compton effect (quantum shift) was obtained, and on decreasing the intensity and increasing the time of exposure of the photographic plate, the Duane shift (tertiary radiation) appeared faintly. An additional note states that measurement of the total intensity of scattered radiation in circumstances including both effects has shown that, contrary to expectation, it is proportional to the primary radiation.—E. B. **Wilson**: Coulomb's law and the hydrogen spectrum. Working from the simple equations for force, quantum condition, frequency condition, spectral law and energy, for the electron moving in a circular orbit, it is shown that either Coulomb's law holds, or the law of inverse cubes, involving a quantised force and potential energy, but with no restriction as to the size of the orbit.—Carl **Barus**: Density and diffusion measurement by displacement interferometry in extreme cases. Very high values were obtained for hydrogen; it appears that there is a static error, referred temporarily to the surface tension of the mercury in the gauge.—L. B. **Loeb** and M. F. **Ashley**: Ionic mobilities in gaseous mixtures. The behaviour of ions in gases has been ascribed to two causes: the clustering of neutral molecules about a charged molecule (cluster ion theory); and the attractive forces of a single charged molecule on surrounding neutral molecules (small ion theory). Experiments on carefully prepared ammonia give results which, when related to the concentration of ammonia, are intermediate between what might be expected from the "cluster" and from the "small" ion theories. They are in accord with the hypothesis that mobility varies inversely as the square root of the molecular weight of the gas multiplied by the dielectric constant minus one. This modification of Kaufmann's law can be derived from Sir J. J. Thomson's equations for the mobility of ions.—R. L. **Moore**: Concerning upper semi-continuous collections of continua which do not separate a given continuum.—George E. **Hale**: The spectrohelioscope (see NATURE, Oct. 25, p. 628).—M. T. **Bogert** and J. J. **Ritter**: The constitution of the so-called "Pechmann dyes," and the mechanism of their formation from *beta*-benzoylacrylic acid. These highly coloured dyes, discovered by von Pechmann more than forty years ago, have the same percentage composition as naphthaquinones, but their constitution is different. *Beta*-benzoylacrylic acid seems to be transformed to the enolic form, which then loses water and condenses to a dilactone containing the indigo chromatophore.

Diary of Societies.

SATURDAY, NOVEMBER 8.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10 A.M.—Dr. J. Kerr Love: Some Neglected Corners of the Otological Field (Presidential Address).

MONDAY, NOVEMBER 10.

ROYAL IRISH ACADEMY (Dublin), at 4.15.

BIOCHEMICAL SOCIETY (in Physiological Department, St. Bartholomew's Hospital), at 5.—G. Thomas: Micro-estimation of Urea in 0·2 c.cm. of Blood.—E. Holmes: Excretion of Salicyluric Acid after Ingestion of Sodium Salicylate by the Human Subject.—R. E. Chapman: Carbohydrate Enzymes of Starch-free Monocotyledons.—E. M. Hume and H. Henderson Smith: Effect of Ultra-violet Irradiation of Environment on Growth and Calcification of Rats fed on Vitamin A-deficient Diet.—G. A. Harrison: Effect of Insulin on Cholesterolæmia.—R. L. Mackenzie Wallis: Observations on Glucose and Lævulose Tolerance Tests.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5.—Major R. W. G. Hingston: Physiological Difficulties in the Ascent of Mount Everest.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—P. Dunsheath and others: Discussion on Research in the Cable Industry.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle-on-Tyne), at 7.15.—S. C. Bartholomew: Power Circuit Interference with Telegraphs and Telephones.

INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—C. E. Henshaw: An Outline of the Process of Casting in Bronze by the "Cire Perdue" Method.

ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street, W.C.), at 8.—Judge Dowdall: What is a Society?

SURVEYORS' INSTITUTION, at 8.

MEDICAL SOCIETY OF LONDON, at 8.30.—Dr. E. F. Buzzard and others: Discussion on Encephalitis Lethargica.

CAMBRIDGE PHILOSOPHICAL SOCIETY (in Anatomy School, Cambridge), at 8.45.—Sir Ernest Rutherford: The Natural and Artificial Disintegration of Elements.

TUESDAY, NOVEMBER 11.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. C. Singer: The History of Anatomy (Fitzpatrick Lectures) (1).

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7.—D. E. Batty: The Electric Road Vehicle—its Characteristics and its Economic Field of Usefulness.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—T. B. Johnson: Chairman's Address.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at 207 Bath Street, Glasgow), at 7.30.—A. Lindsay: Chairman's Address.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—G. C. Robson: Brackish Water Fauna.

INSTITUTE OF CHEMISTRY (Students' Association, London), at 8.—Debate.

WEDNESDAY, NOVEMBER 12.

PREHISTORIC SOCIETY OF EAST ANGLIA (at Geological Society), at 2.15.—Dr. C. Fox: A Settlement of the Early Iron Age at Abington Pigotts, Cambs.—H. Dewey and J. P. T. Burchell: The Gravels at Reculver, Kent.—R. A. Smith and W. H. Cook: Report on the Discovery of a St. Acheul-Moustier Floor near Rochester, Kent.—A. L. Armstrong: Recent Excavations at Grimes' Graves.—J. Witham: An Account of Researches and Discoveries in the Burnley District of S.E. Lancashire.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Sir Richard Owen as Conservator (Thomas Vicary Lecture).

NEWCOMEN SOCIETY (Annual General Meeting) (at Caxton Hall, Westminster), at 5.30.—T. Rowatt: Some Original Models of Smeaton's Eddystone Lighthouse.

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7.—Discussion on the New I.E.E. Wiring Regulations (Buildings).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduates Section) (at Bolbec Hall, Newcastle-on-Tyne), at 7.—G. L. Hutchinson: The Corrugated Ship.

INSTITUTION OF AUTOMOBILE ENGINEERS (Birmingham Graduates Section) (at Chamber of Commerce, Birmingham).

THURSDAY, NOVEMBER 13.

ROYAL SOCIETY, at 4.30.—N. K. Adam and J. W. W. Dyer: The Molecular Structure of Thin Films. Part VI.—T. Alty: The Cataphoresis of Gas Bubbles in Water.—*To be read in title only*:—D. R. Hartree: Some Relations between the Optical Spectra of Different Atoms of the same Electron Structure. I. Lithium-like and Sodium-like Atoms.—P. A. M. Dirac: The Conditions for Statistical Equilibrium between Atoms, Electrons, and Radiation.—Ida Doubleday: Boundary Lubrication. Further Consideration of the Influence of the Composition of the Solid Face.—Christina C. Miller: The Stokes-Einstein Law for Diffusion in Solution.—Helen S. French and Prof. T. M. Lowry: Studies of Co-ordination. Part I. Absorption Spectra and Co-ordination of some Cupric Compounds.—L. F. Bates: The Range of α-Particles in Rare Gases.—D. H. Black: The β-Ray Spectrum of Mesothorium 2.—J. Keith Roberts: The Thermal Expansion of Crystals of Metallic Bismuth.—R. Stoneley: Elastic Waves at the Surface of Separation of Two Solids.

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Engineers' Club, 39 Coventry Street, W.), at 5.—F. M. Potter, H. C. Marris, and others: Discussion on Chemical Works Costs.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. C. Singer: The History of Anatomy (Fitzpatrick Lectures) (2).

LONDON MATHEMATICAL SOCIETY (Annual General Meeting) (at Royal Astronomical Society), at 5.—Prof. W. H. Young: The Progress of Mathematical Analysis in the Twentieth Century (Presid Address).—H. Causdale: General Equation of the n-th Degree.—Chaundy: Poncelet's Poristic Polygons (Second Paper).—Pr Hilton: Successive Evolutes of a Plane Curve.—E. L. Ince: Th Zeros of Solutions of a Linear Differential Equation with Period efficients.—A. E. Ingham: Some Tauberian Theorems of Hard Littlewood.—J. E. Littlewood: The Riemann Zeta Function.—Milne: Contravariant Envelopes of the Plane Quartic Curve.—Titchmarsh: (1) The Convergence of Certain Integrals; (2) An Inv Formula involving Bessel Functions.—Dr. D. M. Wrinch: A Cl Problems in Electrostatics and Hydrodynamics.

ROYAL AERONAUTICAL SOCIETY (at 7 Abermarle Street, W.), at 5 Prof. L. Bairstow: Skin Friction.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Comma Mary Allen: Women Police Work among Children.

OPTICAL SOCIETY (at Imperial College of Science and Technolog 7.30.—T. Smith: (*a*) The Back Vertex Power of a Combinati Lenses; (*b*) The Theory of Neutralisation.—R. Kingslake: A Type of Nephelometer.

INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Section) (at U sity College, Dundee), at 7.30.—G. Rogers: Automatic and Automatic Mercury-Vapour Rectifier Substations.

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre) (at Trinity Co Dublin), at 7.45.—Discussion on the New I.E.E. Wiring Regula (Buildings).

INSTITUTE OF METALS (London Local Section) (at Royal School of M at 8.—Prof. T. Turner: Oxidation, with special reference to Films.

INSTITUTION OF MECHANICAL ENGINEERS (Cardiff Section).

SOCIETY OF DYERS AND COLOURISTS (Bradford Junior Branch Bradford).—L. S. Priestley: The Conditioning of Cotton and Art Silk.

FRIDAY, NOVEMBER 14.

DIESEL ENGINE USERS' ASSOCIATION (at Engineers' Club, Coventry St W.), at 3.30.—Further Report of Committee on Heavy Oil E Working Costs.

ROYAL ASTRONOMICAL SOCIETY, at 5.—T. C. Hudson: Perturbati Directivity.—Prof. I. Yamamoto: Some Relations between the Constant and Solar Activity.—Prof. W. G. Duffield: The Proble Measuring Gravity at Sea.—M. C. Johnson: Scattering and Absor in the Atmospheres of Emission Line Stars.—A. Buxton: Not Expressions for the Measurement of the Effect of Diffraction and Presence of Optical Aberrations in the Images of Point, Line, and P Luminous Sources.—N. Goryatchew: Occultations of Stars by the M observed at the University Observatory, Tomsk, Siberia, 1923, 19 Dr. J. Lunt: The Spectrum of Germanium.—S. D. Tscherny: Occ tion of Venus by the Moon, 1924, Sept. 24, observed at the Astronon Observatory, Kiew.—W. S. Franks: Observed Colours of 205 Red S —N. Liapin: The Transit of Mercury across the Sun's Disc, 1924, M as observed at the University Observatory, Simferopol, Crimea.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at D. W. Dye and L. Hartshorn: The Dielectric Properties of Mic Dr. L. Simons: The X-ray Emission of Electrons from Metal Fi with Special Reference to the Region of the Absorption Lim Dr. W. H. Eccles: Demonstration of an Electrical Method of thesising Vowel Sounds.

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (at Ardrossan), at J. G. Roberts: Chemical Pottery.

JUNIOR INSTITUTION OF ENGINEERS (Annual General Meeting), at 7.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—G. Aven Round about Swanage (Lantern Lecture).

INSTITUTE OF METALS (Swansea Local Section) (at University Coll Swansea), at 7.15.—Dr. W. Rosenhain: The Inner Structure of Allo

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS Newcastle-upon-Tyne), at 7.30.—J. F. King: Girders in Ships.

INSTITUTION OF MECHANICAL ENGINEERS (Leeds Section).—Vice-Adm Sir George G. Goodwin: The Trend of Development of Marine Propel Machinery (Thomas Hawksley Lecture).

SOCIETY OF DYERS AND COLOURISTS (Manchester Junior Branch) Manchester).—Dr. R. S. Willows: Studies in Liquid Films.

SATURDAY, NOVEMBER 15.

PHYSIOLOGICAL SOCIETY (at London Hospital).

PUBLIC LECTURES.

SATURDAY, NOVEMBER 8.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—E. Lovett: The Amulets Ancient Egypt and Modern London.

WEDNESDAY, NOVEMBER 12.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Sir Leonard Rogers: Lepr as an Imperial Problem.

UNIVERSITY COLLEGE, at 5.30.—J. C. Gröndahl: Nature Feeling Norwegian Literature. (Succeeding Lectures on November 19, 26. G. F. Barwick: The British Museum Library—I. The Reading Roon

THURSDAY, NOVEMBER 13.

BEDFORD COLLEGE FOR WOMEN, at 5.15.—Prof. W. Wilson: Atoi Structure and Quanta.

UNIVERSITY COLLEGE, at 5.30.—Dr. C. Pellizzi: La dottrina sociali storica di G. B. Vico (in Italian).

FRIDAY, NOVEMBER 14.

KING'S COLLEGE, at 5.30.—Prof. L. T. Hobhouse: Scientific Method.

SATURDAY, NOVEMBER 15.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. H. S. Harrison: Evolut and Darwinism.

The State and Productive Research.[1]

BY Order in Council of July 28, 1915, the Committee of the Privy Council for Scientific and Industrial Research was established "to direct, subject to such conditions as the Treasury may from time to time prescribe, the application of any sums of money provided by Parliament for the organisation and development of scientific and industrial research." The Order in Council further provided that there should be an Advisory Council to which should stand referred, for its report and recommendation, proposals—(1) for instituting specific researches; (2) for establishing or developing special institutions or departments of existing institutions for the scientific study of problems affecting particular industries and trades; and (3) for the establishment and award of research studentships and fellowships.

On December 1, 1916, the work of the Committee of Council for Scientific and Industrial Research with that of its Advisory Council, hitherto under the ægis of the Board of Education, was assigned to a separate department—the Department of Scientific and Industrial Research—having its own estimates in charge of a minister responsible to Parliament. This was followed by the creation, under His Majesty's Sign Manual, of the Imperial Trust for the Encouragement of Scientific and Industrial Research, to hold funds, to enter into contracts and agreements, and to do other things in furtherance of the objects of the Committee of Council for Scientific and Industrial Research.

Parliament having voted the sum of one million sterling for the purposes of the Department, the fund was deposited with the Imperial Trust to be expended in accordance with the directions of the Committee of Council. On the recommendation of the Advisory Council, the Committee of Council decided that the money should be spent in the form of grants in aid of research in any industry undertaken by firms which might combine to conduct it on a co-operative basis. The means devised to this end was the establishment under the Companies Acts of Associations for Research limited by guarantee and trading without profit. The number of these industrial research associations in actual operation to-day is twenty-three, and there is one which has not yet commenced full operations.

The position of the Research Associations and their future in the industrial system of Great Britain are well worth separate consideration, but as the policy of establishing them at all has been challenged, even in quarters unquestionably anxious to promote the fullest use of scientific knowledge, it may be well to say a

[1] Report of the Committee of the Privy Council for Scientific and Industrial Research for the year 1923–24. (Cmd. 2223.) Pp. iv+139. (London: H.M. Stationery Office, 1924.) 3s. net.

word on the general question. That question is, granted that a million fund is for disposal to bring the results of scientific research to the continuous aid of industry, is the method of establishing research associations the best method, or at least as effective as any other method, of doing so? The Advisory Council, in its annual report for 1919–20, says:

"It may be said that a million spent upon research work done at the National Physical Laboratory and other research laboratories up and down the country would produce much greater scientific results of value to industry than the same sum spent in subventions to associations that have to buy their experience as well as their staff and equipment at a time when the country is short of both. It may be so. But it is only after the industries have done research for themselves that they can appreciate either its difficulty or its worth. They are trained to suspect that what can be got for nothing may have a corresponding value. Had the million been spent on research directed by the Government itself, its effect upon manufacturers would at the best have been destructive of their self-reliance and at the worst a free gift to their competitors in other lands."

To the writer these considerations seem sound and over-riding. The essential problem would not be solved by the mere increase, in quantity and quality, of the results of scientific research of value, direct and indirect, to industry. It was a part, and not the least part, of the problem to get science domiciled in the industries themselves; to bring about an interfusion, not only of the theoretical knowledge of the man of science and the practical knowledge of the manufacturer, but also of the corresponding personalities; and to make the manufacturers themselves (in greater or less degree, according to the character of the industry) working, and not sleeping, partners in scientific research. It is difficult to see what better means to these ends could have been adopted than the method of industrial research associations.

On one major point, however, there may well be doubt and criticism. The scheme was based on the expectation that at the end of the first five years the industries concerned would find themselves both willing and able to continue the work of their respective research associations without direct assistance from the State. On this, two things may be said. In the first place, five years is too short a period in which to bring practical conviction of the benefits and necessity of co-operative research to industries, presumably, needing to be convinced, and the course of economic events since the War, including the long period of industrial depression, has enhanced this difficulty. In the second place, the State may well lose more of real wealth by cutting the research associations adrift than it can gain in money saved by the withdrawal of grants in aid. It is to be hoped that the Committee of Council will give further careful consideration to this aspect of the question and will not regard as an axiomatic principle the proposition that research associations must, after a limited period, "look solely to the industries they represent for their maintenance."

To obtain a just idea of the work of the Department of Scientific and Industrial Research, we have to consider, however, much more than the work of the Research Associations. In carrying out its duties, the Advisory Council gradually evolved a definite programme under four main heads: (1) the encouragement of the individual research worker, particularly in pure science; (2) the organisation of national industries into co-operative research associations; (3) the direction and co-ordination of research for national purposes; and (4) the aiding of suitable researches undertaken by scientific and professional societies and organisations. It would be impossible in a single article to give even the barest summary of the work done under these heads, and the reader who is interested may be referred to the annual reports of the Department. There, for example, he will learn what has been done and attempted "in the direction and co-ordination of research for national purposes" in the records of the Fuel Research Board, the Food Investigation Board, Forest Products Research Board, Building Research Board, and so on.

The Department has also done much to co-ordinate the various scientific activities of government. In 1918 the property of the National Physical Laboratory, together with the responsibility for its maintenance and development, was transferred to the Department, and in 1919 the administration of the Geological Survey and Museum was similarly transferred. In 1919–20 on the decision of the Cabinet, Co-ordinating Boards were established, with the object of so organising all the scientific work which is of common interest to the Fighting Services of the Crown as to ensure the utmost economy of expense and personnel, and the due co-ordination of the technical work of the various naval, military, and aeronautical establishments so as to avoid overlapping, either with each other or with the research organisations of the Civil Departments of State. At present there are four such Co-ordinating Boards, for chemistry, engineering, physics, and radio research. They include technical representatives of the Fighting Services and Civil Departments.

Reviewing the work and development of the Department of Scientific and Industrial Research since its foundation, the question arises, has the experiment of governmental participation in the organisation of scientific research, especially in its relation to industry, so far as it has gone, been justified? To that question,

ere can be little doubt that the answer is in the irmative. If there have been mistakes in detail, realised expectation here and, apparently, wasted ort there, the instances have been at least as few as, d perhaps fewer than, could reasonably be counted , for a like period, in the early stages of development any new government department. As to the value the work itself, it is sufficient to quote the words of e Advisory Council: "Scientific research is, in our dgment, the main, if not the only source of fresh oductivity in industry, and it is only by increased oductivity that the world will find a way out of its esent economic difficulties."

What, taking a broad view, has been done towards is end by the establishment and work of the Depart-ent of Scientific and Industrial Research?

We have now a Government Department as fiduciary r science, charged with the duty and responsibility ensuring, in so far as Government can ensure, that ientific knowledge and methods play their full part the Government services and in the trade and dustry of Great Britain.

We have Research Associations in twenty-three or wenty-four diverse industries, not only engaged directly scientific research, but also acting as scientific centres here all scientific questions affecting their respective dustries can be brought to a focus, and in the solution f which the scientific worker, the manufacturer, and he user can each play his appropriate and co-ordinated art.

The scientific worker and the manufacturer have been brought into closer co-operation, the gulf between heory and practice has been narrowed, and, in greater r less degree, the manufacturers themselves have become productive partners in research.

The spirit of co-operation between individual firms n an industry and between industries generally and the Government services has been quickened and enlarged.

Researches have been initiated and prosecuted, already with appreciable success, into fundamental problems of national importance (for example, fuel, food, and building materials), which no one firm and no one industry could be expected to undertake on an adequate scale.

The man of science has been helped to come into his own, and a powerful reinforcement has been brought to the aid of those who have long sought to bring vividly to the minds of all classes a realisation of the degree and extent to which our modern industrial civilisation is based upon, and must be shaped by, the progress of scientific discovery.

Not least, a good beginning has been made in the evolution of a national scientific policy. Continuity in foreign policy has been the aim of successive governments since the days of Lord Salisbury. By wise and prudent direction, by advancing, to use a phrase of Lord Morley, "with daring caution," the Department of Scientific and Industrial Research may give us an accepted national scientific policy, definite, continuous, and consistent.

J. W. WILLIAMSON.

History of Mathematics.

History of Mathematics. By David Eugene Smith. Vol. 1: General Survey of the History of Elementary Mathematics. Pp. xxii + 596. (Boston and London: Ginn and Co., 1923.) 21*s.* net.

IT is only during the last fifty or sixty years that the history of mathematics has been systematically studied. In that time, however, the field has been gradually covered by an increasing number of students, and their output has become so extensive that it was no work of supererogation when Prof. Gino Loria thought it necessary to publish a guide to the literature of the subject, old and new, "Guida allo studio della storia delle matematiche" (Hoepli, 1916). There are indeed already in existence general histories of mathematics of all sorts and sizes, designed to meet the requirements of almost all varieties of readers. The great work of Moritz Cantor ("Vorlesungen über Geschichte der Mathematik"), which may be regarded as the inspirer of most of them, appeared in the years from 1880 to 1908 and consists of four volumes, with an aggregate of some 3800 large pages. Yet it contains no unnecessary details—in many places in the earlier volumes the reverse is the case—and it does not carry the story beyond 1799: this is a sufficient indication of the extent of the material.

Cantor's history has not been translated into English, partly, we may suppose, because it would be a formidable undertaking, but also, no doubt, because the book is, so far as the early volumes are concerned, already out-of-date, the later editions having failed to take sufficient account of the results of recent researches and of the many corrections and well-founded criticisms of details in the first edition. Among the shorter histories covering approximately the same ground may be mentioned the "Geschichte der Mathematik" designed for the "Sammlung Schubert," in two volumes, the first (1908) by Siegmund Günther (pp. 427), and the second in two parts (1911 and 1921) by Heinrich Wieleitner (pp. 251 and 220), a competent work of convenient size. Much smaller still was the "Geschichte der Mathematik" in the "Sammlung Göschen," by A. Sturm, which essayed to tell the story in 155 small pages; this has now been re-edited in two parts (1922–1923) by Wieleitner (pp. 136 and 154), and contains the very utmost that could be compressed into the small space, so much so that it can scarcely be read continuously for any length of time without inducing a headache.

The histories in French, apart from the pioneer work of Montucla (first edition 1758, second edition, completed by Lalande, 1799–1802), are of no great account. One is by M. Marie in twelve slender volumes ("Histoire

des sciences mathématiques et physiques," 1883–1888); the volumes relating to antiquity are, however, untrustworthy. Another by F. Hoefer (1874) has passed through several editions, but is now out-of-date. A third, by J. Boyer (1900), is a mere sketch in 260 pages, but it has some interesting portraits. In English we have the work by W. W. Rouse Ball with the modest title "A Short Account of the History of Mathematics" (first edition 1888), an attractive book the success of which is proved by the number of editions that have been called for; there is also the slighter "History of Elementary Mathematics" by Florian Cajori (New York: The Macmillan Company, 1897).

Cantor was able to complete the first three volumes of his "Vorlesungen" himself, covering the period down to 1758; but for the fourth volume dealing with the period from 1759 to 1799, he was constrained to enlist the co-operation of other specialists, each of whom took one department or section; thus S. Günther wrote upon the works bearing on the history of mathematics which belong to the period in question, F. Cajori on arithmetic, the theory of equations and the theory of numbers, E. Netto on combinatorial analysis, probability, series and the imaginary, V. Bobynin on elementary geometry, A. von Braunmühl on trigonometry, polygonometry and tables; and so on. This devolution of the work meant a change of arrangement; whereas the earlier volumes all followed chronological order, the fourth volume abandoned this plan in favour of an arrangement by subjects. This becomes a necessity if the development of the several branches of mathematics is to be systematically set forth and properly understood. The chronological method with a proper admixture of biography and anecdote is no doubt more suitable for the ordinary cultivated reader with just a sufficient mathematical equipment to enable him to understand what he is reading; the other arrangement, according to subjects, better serves the purpose of the expert mathematician, amateur or professional.

This was seen by J. Tropfke, who in the years 1901 to 1903 brought out the two volumes of his "Geschichte der Mathematik in systematischer Darstellung" (1922 saw the commencement of publication of a second edition). This excellent work is divided into fourteen sections dealing with separate subjects, namely, arithmetical calculation, algebra, plane geometry, logarithms, plane trigonometry, sphaeric and spherical trigonometry, series, interest-calculations, combinatory analysis and probability, continued fractions, solid geometry, analytical geometry, conics, maxima and minima. Thus, whereas the earlier histories adopted, after Cantor, a chronological arrangement, Tropfke's amounted rather to a series of historical monographs on the origins and development of the main subjects included in a regular programme of mathematical instruction.

Dr. Smith, in the two volumes into which his work is divided, aims at fulfilling a double purpose. The first volume, now before us, is designed to afford a survey of the growth of mathematics by chronological periods, and to give a general historical presentation "for the purpose" (in his own words) "of relating the development of mathematics to the development of the race, of revealing the science as a great stream rather than a static mass, and of emphasizing the human element." "But this" (he continues) "ought to lead to a topical presentation by which the student may understand something of the life history of the special subject which he may be studying, whether it be the elementary theory of numbers, the methods of calculation, the solution of equations, the functions of trigonometry, the common symbolism in use, the various types of elementary geometry, the early steps in the calculus, or one of the various other important topics of elementary mathematics." This latter presentation of the subject is reserved for the forthcoming second volume. We may say therefore, roughly, that our author seeks to combine the aims of writers like Rouse Ball on one hand and of Tropfke on the other, the first volume of his work corresponding to Rouse Ball's "Short Account" and the second to Tropfke's history.

We can only wish Dr. Smith success in his undertaking. There is certainly room for a volume in English on Tropfke's plan, while the first volume is in many ways attractive. It is true that, in comparison with Ball's "Short Account," the first volume has a certain disadvantage in that, when the author would naturally give us some piece of actual mathematical work, he has (in order to avoid repetition) to break off and refer us, for details, to the forthcoming volume. While, therefore, he is able, like Ball, to give details of the lives of mathematicians and stories about them which contribute to make the volume eminently readable, some portions of certain chapters tend to become little more than lists of names of writers with a statement of the subjects on which they wrote or in which they were interested. Dr. Smith is, however, fully aware of this disadvantage. On the other hand, there are special features which add to the usefulness and attractiveness of the volume. One is the remarkably full references in the notes to the literature and bibliography of the subject, for which students who desire to pursue it further cannot fail to be grateful. Another is the large number of portraits of mathematicians (on which Dr. Smith is a recognised authority), and of facsimiles of pages from manuscripts and rare and famous printed books, as well as of extracts from letters

memoranda in the handwriting of the most famous mathematicians. The facsimiles, unfortunately, have often to be on a reduced scale, but this is rendered inevitable by the size of the page.

In a work containing so much detail it is, of course, impossible to avoid occasional slips. To take only the section dealing with Greek mathematics:—We are puzzled by the statement on p. 73 that "for the doctrines of Pythagoras we are indebted chiefly to Eudoxus of Cnidus (*c.* 370 B.C.), whose works, though lost, are known to us through extracts preserved by later writers"; is the reference, perhaps, intended to be to Eudemus of Rhodes? On p. 86 we are told, as regards Theaetetus, that "there are references in the writings of the ancient historians to show that he discovered a considerable part of elementary geometry and wrote upon loci." We know of no authority for the statement that Theaetetus wrote on loci; is it possibly due to an inadvertent mis-reading of the dictum in Proclus's "Summary" [that "*Hermotimus of Colophon* carried further the investigations already opened up by Eudoxus and Theaetetus, discovered many propositions of the Elements and compiled some portion of the theory of loci"? The statements, on p. 59, that the Egyptians knew the fact relating to the square on the hypotenuse of a right-angled triangle long before Pythagoras, and on p. 72, that we have the best evidence for this, need modification since the publication of the new edition of the Rhind Mathematical Papyrus by Prof. Eric Peet; for we are assured by Prof. Peet that he has been able to find no foundation whatever for the idea that the Egyptians knew the fact in question, and that nothing in Egyptian mathematics suggests that the Egyptians were acquainted even with special cases of the Pythagorean theorem. T. L. H.

Tissue Growth.

Growth. By G. R. de Beer. Pp. viii + 120 + 8 plates. (London: E. Arnold and Co., 1924.) 7*s.* 6*d.* net.

THE experimental study of tissue growth is a comparatively recent branch of biological research, and as yet but a small part of this vast field has been explored. Much important work, often of tantalising suggestiveness, has already been carried out, however, and various hypotheses have been put forward to explain the forces which initiate, sustain, perpetuate and control the growth of cells. At the present time the problem of growth is being approached from many widely diverse points of view. The embryologist, the physiologist, the geneticist, the biochemist are all engaged upon its solution, and it is therefore a matter of some difficulty for the layman, or indeed for the specialised research worker, to obtain a comprehensive view of the more significant facts which recent investigation has brought to light. Mr. G. R. de Beer, in his book "Growth," has successfully summarised and discussed in popular language some of the results achieved in relation to this subject in various branches of science during recent years.

The author opens his introductory chapter with a statement of the object of his book, "to show what growth is, what it does, and how it does it"—perhaps a somewhat ambitious aim in the present state of our knowledge. If he could satisfactorily explain the third division of his text, "how it does it," he would have solved one of the most perplexing problems in Nature. He has, however, brought together a number of interesting experiments and observations relative to growth in the plant and animal kingdoms in a clear, concise, and interesting manner. It is pointed out that growth alone is not responsible for the formation of an intricate adult organism out of a simple spherical ovum, but that the many complex processes involved in embryonic development fall into two headings: increase in size and increase in complexity of structure and shape, or, in other words, growth and differentiation. A short account of the growth of animals, the development of the frog being selected as the example, is followed by a brief description of growth in plants and a short chapter containing a few special examples of growth and differentiation in animals.

Growth, it is pointed out, is not confined to embryonic life; the processes of adult existence—metabolism and expenditure of energy—entail a continual breaking down of the tissues which must be replaced if the organism is to persist. This physiological regeneration goes on throughout life and is effected by cell division, but does not necessarily cause any increase in size. A very striking example of normal regeneration is quoted, which occurs regularly among the Polyzoa. In these animals the nervous and alimentary system degenerates into a mass of decomposing matter, and at the same time a new alimentary canal and nervous system are produced by growth. As Mr. de Beer remarks, this form of regeneration "is a very convenient method of 'doing up' the organism." A short chapter is devoted to the question of asexual reproduction, illustrated by various examples from the animal and vegetable kingdom. The author then passes to the subject of abnormal growth, which he defines as growth which plays no part in the normal life cycle of the organism, but rather the reverse, and mentions various examples of galls in plants and tumours in animals. A most remarkable case of abnormal growth here described is that of a fungus *Rozites gongylophora*, "which is carefully cultivated on specially produced manure beds by the leaf-cutting ant

(Atta) in Brazil. Ordinarily this fungus produces spores, but under the treatment to which it is subjected by the ants it grows into white swellings which are used by the ant as food."

Having made a general survey of the various forms of tissue growth, the author proceeds to discuss its causes and nature. He likens protoplasm with its ceaseless metabolism to "a whirlpool which involves now one particle of water, now another"; at no time can it be said that it consists essentially of any particular portion of matter, for the essence of the whirlpool is the "whirl." The genetical aspect of growth is briefly considered along Mendelian lines. The nature of fertilisation is also touched upon, and a short account is given of the more obvious chemical processes which accompany the conversion of non-living food-material into living protoplasm.

Vitamins and hormones, "substances which speed up growth," are accorded a short chapter, which is followed by an interesting account of the effect of external factors upon growth and the relationship of certain physical conditions to the limitation of size in various organisms.

The rate of growth and the control of growth by differentiation and age are discussed, and a chapter on growing smaller or "degrowth" follows. A few pages are devoted to inorganic analogies, growth being compared with crystal formation and other physical and chemical processes. The author wisely concludes, however, that "inorganic analogies, while very instructive and illustrative of certain events in the reactions of living matter, are as yet unable to throw much light on growth itself."

In his final chapter, Mr. de Beer reviews the problem of growth in its more general aspect, and remarks that "there is no need to invoke mystical forces to explain results which in the present state of knowledge are not understood. The processes of growth most certainly have their causes, but these causes are not likely to be understood until the chemical and physical properties of living matter have been thoroughly explored."

It is always a matter for regret that science should guard her treasures from the general public by a bristling array of formidable technicalities, and Mr. de Beer is therefore to be congratulated on reducing our knowledge of one of the most important, and at the same time one of the most difficult subjects in biology, to a form in which it can be appreciated by the man in the street. The results of much important research must of necessity be omitted from a work of this scope, but the material on the whole is well selected, and the volume will be a welcome addition to the shelves of biological students and also, it is to be hoped, to members of the general public.

Physics for All.

(1) *Our Physical World: a Source Book of Physical Nature Study.* By Elliot Rowland Downing. With a Chapter on Radio Communication, by Fred G. Anibal. (University of Chicago Nature-Study Series.) Pp. xviii + 367. (Chicago, Ill.: University of Chicago Press; London: Cambridge University Press, 1924.) 2.50 dollars.

(2) *Matter and Change: an Introduction to Physical and Chemical Science.* By William Cecil Dampier Whetham. Pp. vii + 280 + 3 plates. (Cambridge: At the University Press, 1924.) 7*s.* 6*d.* net.

IT is generally admitted at the present time that science in some shape or form should be part of the general education of every boy. Whatever his main interests are to be, whether he is to be a serious student of other branches of learning, or a man of affairs, it is almost unthinkable that he should leave school without some instruction in the aims and methods of science. In particular, in these times when strange stories of fabulous inventions seem to have replaced the giant gooseberry and the sea-serpent in the columns of the ephemeral press, some knowledge of the principles of physics seems a desirable part of the education of all good citizens; though physics presents, perhaps, his greatest problem to the teacher of "science for all." There is no time, in the few hours which are all that science can claim in a curriculum of general education, for the tedious process by which the "specialist" prepares the foundations for his higher studies in science; nor does it seem desirable that time and energy should be spent on laying elaborate foundations upon which nothing is to be erected subsequently. The selection of material, from so vast a storehouse, the nature of its presentment, the degree of rigour to be aimed at, are engaging the deepest attention of many of our most enthusiastic and capable teachers. It is not surprising that books on the subject multiply rapidly. Two are before us as we write. They reflect, in their extremest form, the divergences which exist as to what is possible and desirable in the way of the teaching of physics as part of a general education.

"Our Physical World," by Prof. Downing, is dated from the School of Education of the University of Chicago, and may be taken to represent the point of view of the practical educational expert, with a vivid—possibly painful—apprehension of the difficulties of his craft, and a realisation of the limitations of the human material with which he has to deal. The schoolboy's attention is to be won, and his interest stimulated, by the proof that science has something to say about subjects which really matter—kites and tin whistles, tops and toy aeroplanes, bows and arrows, and motor cars. The scientific pill must be carefully sugared, and

the exigencies of confectionery leave little space for the operative principles which it is the purpose of the writing to convey, that is one of those unfortunate facts which the teacher must face and accept.

In "Matter and Change," on the other hand, Mr. Whetham has obviously found his subject of such enthralling interest that he has not conjectured the possibility that any reader should find it less so, or should need any inducement beyond the subject itself to pursue his studies with diligence and enthusiasm. Save for the delightful clarity of style, which is a distinguishing feature of all Mr. Whetham's writings, and for the humanising touches provided by illuminating biographies, one line long, which help us to realise that even scientific investigators are men, there is no concession to human weakness or boyish indolence. Probably the true method lies somewhere between these extremes.

(1) Prof. Downing's book, though very readable and well illustrated, does not strike us as one of the best of its kind. Although nominally a "source book" for teachers of the subject, the author frequently appears to be addressing the pupils themselves. We hope, at least, that there are no science teachers in the United States who require the caution that "The North Pole is not a real pole sticking up out of the earth." Nor does it seem that the younger pupils, for whom some of the very elementary portions of the book are clearly intended, could glean much of value from the account of the electron theory of matter, or from the excellent chapter on radio communication. There is a similar want of sureness of purpose in the choice of material. Instructions for making a bird kite are followed by an excellent historical account of the progress and development of aviation, and a description of a toy windmill is followed by an impassioned appeal against allowing the valuable water-power of the States to fall into private hands. A chapter on the electrical theory of matter, including with a two-page synopsis of chemical theory, is succeeded by an historical account (again very well done) of the development of the steam-engine. Later in the volume a chapter on devices for seeing, which might have been taken from a well-written elementary text-book on light, is followed by a chapter of detailed instructions in practical photography, reminiscent of the booklets of instructions given away with a camera outfit. Much of the book is interesting and well written, but it is doubtful whether the pupil will gain from the variety of material supplied that "elementary appreciation of those principles of science" which it is the author's object to instil.

(2) Mr. W. C. Dampier Whetham's volume (granting the existence of a class of non-scientific reader who is willing and able to follow the author in his strenuous course) is excellent. Here is to be found everything of importance which would be found in the pages of an elementary treatise on physics and chemistry, together with many things which could only be found in treatises which are far from elementary. No vital point is omitted, no difficulty slurred over, and though in scarcely more than 250 pages the author leads his readers from the very elements of mechanics to the highest flights of relativity and the quantum theory (taking in chemistry and bio-chemistry by the way), there is scarcely a subject mentioned on which valuable information is not given, and scarcely a point at which the author could fairly be charged with producing the illusion of knowledge without its substance.

"Matter and Change" is a miracle of condensation—to give a list of the subjects dealt with would be to court instant unbelief—and it is not to be expected that the book will be found easy of assimilation, in spite of the clarity of its style. It is not at the first or the second reading that the reader will extract all the marrow which it contains. We should like to see the book introduced into some of those non-scientific classes of schools for the benefit of which, in part, it has been written; expressing, however, at the same time the opinion that should any member of the class find himself thoroughly at home with it, his talents must have been seriously misjudged by his schoolmaster, and he should be transferred without delay to the science sixth.

Any reader who has mastered the contents of this little volume will have a systematic knowledge of physical science of which he will never have reason to be ashamed, and which many honours students in the university might envy him. But to master it he will have to read slowly, to re-read often, and, above all, to think hard. In spite of its brevity, it contains matter for more than one winter evening's entertainment.

J. A. C.

The People of Kilima Njaro.

Kilimanjaro and its People: a History of the Wachagga, their Laws, Customs, and Legends, together with some Account of the Highest Mountain in Africa. By the Hon. Charles Dundas. Pp. 349 + 16 plates. (London: H. F. and G. Witherby, 1924.) 18*s*. net.

KILIMA NJARO has had a varied influence on the history of East Africa. After its discovery by Rebmann in 1848, its problems and the incredulity with which European geographers received the statement that it is snow-capped led to several of the first European journeys into this part of Africa. The sentimental interest felt in the mountain by the German Emperor was one of the determining factors in the demarcation of the Anglo-German boundary. The relative accessibility of this mountain and the beauty

of its scenery has led to its repeated exploration. The latest contribution to its literature is a volume by the Senior Commissioner of Tanganyika Territory, Mr. Dundas, who states in the preface that study of the district and its people was compelled by the spell of the mountain more than by his own interest in research. His first chapter summarises the history of the exploration of the mountain and its glaciers, and reports that their rapid diminution in size since they were first mapped by Hans Meyer in 1887 and 1889 still continues. There is little direct reference to the geological structure and none to the interesting rocks of which the mountain is composed. The author makes for Kilima Njaro the surprising claim that it is the highest point of the British Empire!

The bulk of the work consists of a valuable account of the Wachagga, who live on the lower slopes of the mountain. One of the legends of this tribe refers to fire on Kilima Njaro, which is a possible reminiscence of an eruption; but the reference is so indefinite that it may be only a coincidence, and affords no evidence of recent volcanic activity. Mr. Dundas records various legends similar to the Bible account of the Fall of Man, of the story of Cain, and of the Flood. He is satisfied that these stories have been long known to the tribe, as they were told him by the older members, and if they had been derived from the missionaries they would doubtless have included some from the New Testament. The claim by Merker that the Masai folklore includes some Biblical stories has been distrusted; but the author considers that it is supported by his discoveries of the Chagga legends.

The two chief drawbacks in the book are the absence of references and the brevity of the index; various authorities are quoted in the text, and the reader might lose time in endeavouring to trace them, especially when the names are misspelt, as in the case of Kersten (p. 20). The index is inadequate and the illustrations are sometimes far from the reference to them in the text. Thus opposite p. 192 is a figure of a "Nungu" or "Cursing Stone" dug up from ruins of a fort of the former Chagga Chief Horombo. It is referred to on p. 174, but is not mentioned in the index. The specimen is strikingly like those in South Africa which have been called Kaffir digging stones. The author considers that it was used as the medium for conveying a curse which might be removed by the submission of the offender. The Wachagga are accomplished smiths, and sell their iron work to the adjacent tribes; they buy the metal from the Pare, a tribe living south-south-east of Kilima Njaro. The volume includes a series of Chagga proverbs and an especially valuable chapter on Chagga law and political institutions. It forms a useful addition to East African ethnology.

Our Bookshelf.

Nuovi orizzonti della psicologia sperimentale. P. Agostino Gemelli. Seconda edizione riveduta e aumentata. Pp. xiv+387. (Milano: Società Editrice "Vita e Pensiero," n.d.) 18 lire.

ENGLISH readers of these essays will be disappointed at the lack of reference to the work of the last ten years in psychology, and the book suffers from having neither bibliography nor index. But it is admirably suited by its lucid style and unbiassed criticism to the special purpose for which it was written, namely, as an introduction to experimental psychology for the use of Italian students.

In Italy, we are told, psychology has always been unduly influenced by philosophy. Whereas in Germany, England, and the United States, objective methods have been in the ascendant, experimental work has been discounted in Italy, where there are only two institutes (of Prof. Kiesow at Turin and Prof. Sante di Sanctis in Rome) for psychological research. "The field of psychology is invaded by philosophers, men of letters, dilettantes; people with the best intentions, who are always discussing general questions but have not advanced the science of mind one jot because they have never applied themselves to psychological research by strict methods and mental discipline."

The first essay discusses "Psychology as a Biological Science," and the inadequacy of biological explanation to solve psychological problems. Nevertheless, it is to Fechner, Wundt, and their successors that we owe the methods of experimental research by which mental activity can be described and studied. The second, on "Prejudices against 'Laboratory Psychology,'" insists that objective observation must be extended and reinforced by subjective, *i.e.* introspective, observation as described in the third essay, on "New Method of studying the Psychology of Will and Thought." Here the teaching of Ribot and Binet, and of Külpe at Würzburg, is contrasted with the earlier school of Leipzig.

"The Pathological Method in Psychology" is next considered, with a reminder that the relative and exceptional cannot be estimated as absolute and regular, and that psychology must not be degraded into psychiatry.

The concluding essay deals with "Psychology as the Science of Consciousness." Consciousness is a function of mental life (*vita psichica*) and not co-extensive with it—it is an autonomous synthetic activity. This theory is experimentally justified by recent researches into the origin of judgments and concepts along the lines of the school of Külpe. F. A. W.

Les Moustiques de l'Afrique mineure, de l'Égypte et de la Syrie. Par E. Séguy. (Encyclopédie entomologique, 1.) Pp. 257+29 planches. (Paris: Paul Lechevalier, 1924.) 50 francs.

ALTHOUGH the Culicidæ as a family are perhaps better known now than any other group of insects, our knowledge of all the details of their life-histories is still far from complete, especially as regards the species of certain regions. The author of the work under notice

of opinion that the mosquito fauna of North Africa and Asia Minor is less known than that of any other malarious region, which was certainly true until very recently. As shown by this volume, however, the deficiency is now to a large extent made good. The main title of the work is somewhat misleading, as it includes a fairly detailed account of nearly all the European mosquitoes, on the quite justifiable ground that many or most of them will be found eventually in the regions under consideration. The treatment is mainly from the systematic point of view, but larvæ as well as adults are discussed and distinguished, as is essential for practical purposes. The bulk of the text is a compilation from previous publications of the author and other workers in this field, but there are some 200 original and carefully executed drawings of structural details, which in themselves will render the work of much value to students. The author, like other systematists, to some extent follows his own inclination as to nomenclature and classification, but the views of others are made clear by full references. His attempt to divide the biting mosquitoes into three subfamilies is not very successful. There are a number of minor errors and inconsistencies, which appear to be chiefly due to too hasty compilation (compare, for example, the references to *Dixa submaculata* on pp. 177 and 179). The volume concludes with a catalogue of Palæarctic and Nearctic Culicidæ, together with a number of maps showing the distribution of some of the more interesting species; some of these, it must be admitted, are partly hypothetical.

Leitfossilien aus dem Pflanzen- und Tierreich in systematischen Anordnung. Von Prof. Dr. Johannes Felix. Zweite, neubearbeitete Auflage. Pp. vii+228. (Leipzig: Wilhelm Engelmann, 1924.) 7 marks.

This is undisguisedly a student's text-book of fossils. There is practically no discussion of phylogenetic relationships: the organisms treated of are arranged, not according to the formations in which they occur, but according to their presumed place in the systematic arrangement. The classification adopted can only be described as antique. Thus sponges are regarded as a division of Cœlenterata. Trilobites are regarded as "Crustacea," and a picture is given of an obscure and incorrect restoration of a trilobite by Jæckel, whilst the infinitely clearer and more correct restoration given by Beecher, the discoverer of the trilobite limbs, is ignored. "Ganoidea" is still recognised as a division of Pisces, and a phylum named "Vermes" appears. Fortunately, since fossils only are described, this is practically coterminous with Annelida.

These blemishes are, however, of less importance in a book which is evidently intended merely as a handy reference manual for elementary students. Very fair figures are given of the known structure of what might be termed "difficult" fossils. Thus we have sections of Nummulina, of Stromatopora, figures of some leading types of crinoids, a longitudinal section of the brachiopod Waldheimia, and of the lamellibranch Hippurites, and of the rod-like shell of the cephalopod Endoceras.

Of course, there are numerous illustrations of vertebrate fossils; but as showing the lack of modern information, we may refer to the skull of the stegocephalous amphibian shown on p. 164, where the covering bones are shown. The names given to these are those to be found in Huxley's "Vertebrata," published in 1871. We think that even in an elementary text-book the student should learn the terms actually in use at the present day. E. W. M.

Die spezielle Relativitätstheorie Einsteins und die Logik. By Dr. J. H. Tummers. Pp. 15. (Venlo, Holland, 1924.) 1*s*.

This pamphlet gives a clear account of the fundamental bases of Einstein's special theory of relativity from the point of view of the logician. The author reaches the conclusion, with which relativists no doubt will agree, that Einstein's fundamental postulates of relativity and of the constancy of the velocity of light are logically inconsistent with each other so long as the absolute character of simultaneity is insisted upon. Moreover, he agrees with Einstein in his further conclusion that the two postulates together require that simultaneity be relative, in so far as two events, which happen at the same time for one observer, happen at different times for another observer in uniform motion relative to the first. But he maintains that, because the two fundamental principles are themselves merely postulates, the conclusion that simultaneity is relative is not proved, but merely postulated, and consequently its acceptance fails to remove the original contradiction between the two fundamental principles. Thus, he argues, we must reject the principle of relativity, if we accept that of the constancy of light-velocity, and admit that simultaneity is absolute, as we did before the introduction of Einstein's theory, a procedure which is tantamount to rejecting that theory as out of touch with reality.

Relativists will scarcely accept the author's sweeping conclusions; they will prefer to adopt the three admittedly consistent postulates of relativity, constancy of light-velocity, and relative simultaneity, rather than reject Einstein's theory, which, after all, has been very successful in co-ordinating many experimental facts not explained satisfactorily by any other theory—an achievement which the author seems to ignore entirely.

A Course of Instruction in Instrumental Methods of Chemical Analysis. By Prof. W. N. Lacey. Pp. vii+95. (New York: The Macmillan Co.; London Macmillan and Co., Ltd., 1924.) 7*s*. net.

One of the difficulties experienced by students desirous of becoming acquainted with the technical analysis of materials is that the description of the apparatus employed is scattered throughout a voluminous literature. In this little volume an account is given of the principles underlying the use of instruments such as viscosimeters, pyrometers, refractometers, colorimeters, and so on, together with a clear statement of the utility and limitations of some of the types of apparatus. The sections are concise and to the point, and the practical work is well arranged. A valuable feature is the set of questions printed at the end of each section. These have been selected to bring out the essential features of the instruments and the value of the results to be anticipated from their use. A useful appendix

gives a list of materials and apparatus needed for each instrument.

Electrometric methods are now of such importance in practice that the section on "Electrometric Analysis" is to be welcomed as an introduction to the subject. In the reviewer's opinion, the pages devoted to "fire assaying" might well be omitted in favour of an addition to the description of electrometric measurements, particularly as the art of dry assaying is one requiring long experience.

The book serves as an excellent introduction to the subject, and is well worth the attention of students of chemical technology. J. J. F.

The Philosophy of "As if": a System of the Theoretical, Practical and Religious Fictions of Mankind. By H. Vaihinger. Translated by C. K. Ogden. (International Library of Psychology, Philosophy and Scientific Method.) Pp. xlviii + 370. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co., Inc., 1924.) 25*s.* net.

PROF. VAIHINGER'S work, now translated into English, has been well known by philosophers almost from its first appearance in 1911. The translation is made from the sixth edition of the original, specially revised by the author to meet the case of historical references which might be obscure to the English reader. The doctrine is that "'as if,' *i.e.* appearance, the consciously false, plays an enormous part in science, in world-philosophies, and in life." The basis of the theory is Kant's doctrine of the Ideas of Reason, God, Freedom, and Immortality. These Ideas, according to Prof. Vaihinger's reading of the Critique, are not objects of knowledge the existence of which, though it cannot be proved by pure reason, is a necessity of the practical reason. He holds, on the contrary, that they are conscious fictions, and that the condition of our human activity is that we must act "as if" they were true. The same principle he holds applies not only to Ideas of Reason but also to all the categories of the understanding, in fact throughout the realms of science and philosophy.

Electrode Reaction and Equilibria: a General Discussion held by the Faraday Society, November 1923. Pp. 665-838. (London: The Faraday Society, 1924.) 10*s.* 6*d.* net.

THE general discussions of the Faraday Society continue to fulfil the useful functions which give to that Society its unique position amongst bodies pursuing similar aims in various branches of science. The discussion on "Electrode Reaction and Equilibria" was held on November 26, 1923, in the very worst of conditions as regards weather, but was attended in person by Prof. Biilmann, of Copenhagen, and by Dr. Heyrovsky, of Prague, as well as by the most keenly interested workers in Great Britain. The permanent record of the discussion forms a volume of nearly 200 pages, and contains 18 original contributions on the two related subjects of reversible and of irreversible electrode reactions, which were the subject of consideration at the afternoon and evening meetings. It is impossible to summarise these papers in a brief note; but the usefulness of earlier issues of the series of reprinted general discussions is so well known, that no further commendation of the latest publication is needed to emphasise its value to all who are interested in the subject with which it deals.

Indian Philosophy. By Prof. S. Radhakrishnan. (Library of Philosophy.) Vol. 1. Pp. 684. (London: G. Allen and Unwin, Ltd.; New York: The Macmillan Co., 1923.) 21*s.* net.

WE have undoubtedly a vast store of wisdom in the systems of Indian philosophy, and many Western philosophers in the modern period, from Schopenhauer to the Rhys Davids, have drawn inspiration from it. It differs, however, in one very essential particular from Western philosophy, both ancient Greek and modern. It aims at setting our questioning activity at rest by offering us satisfying answers to our problems; it does not stir up in us the restless Socratic spirit of inquiry. The emphasis is on what has been thought out and solved by seer and sage. The study of Indian philosophy, therefore, resembles the study of authoritative religious systems and is unlike the methodology in which our philosophy so largely consists. Prof. Radhakrishnan presents his subject in the form of an encyclopædia of systems. It is a continuous history and also specially useful as a book of reference.

An Introduction to the Practice of Civil Engineering. By E. E. Mann. Pp. xi+296. (London: Macmillan and Co., Ltd., 1924.) 7*s.* 6*d.* net.

THE author's object in preparing this volume has been to render easier the period through which young men have to pass after leaving college. This period is often exceedingly trying, both to the beginner and to those who have to look after him in the civil engineer's office. He may have had a very successful college career, and the work he will most certainly be started on is usually of such a character as to lead him to imagine that a great part of his studies have been useless. Of course this view is quite a mistaken one; responsible work will come later, and the knowledge acquired in college will then be essential to success. The volume before us will be of great service in bridging over the transition period, and we can heartily recommend it to students still pursuing their college course, in order that they may have some idea of what lies before them when they are introduced to the practical work of the civil engineer.

A School Mechanics. By C. V. Durell. (Cambridge Mathematical Series.) Part 1. Pp. xx+186+x. (London: G. Bell and Sons, Ltd., 1924.) 3*s.* 6*d.*

MR. DURELL'S complete work is intended to cover the course required for the School Certificate and the various matriculation examinations. The part before us contains an easy introduction to the subject which should be successful in awakening the interest of the student; its contents are restricted almost entirely to vector quantities located in the same or parallel lines, and cover velocity, acceleration, moments, work, machines, energy, momentum, and the relation of force with acceleration. Gravitational units are employed in the treatment. The author has taken pains to make his subject alive, and the book will be welcomed in such secondary schools as include the systematic teaching of mechanics in their course of work.

Letters to the Editor.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

Luminescence of Solid Nitrogen and the Auroral Spectrum.

In a paper recently published in Proc. Roy. Soc. A. 106, p. 138, Prof. McLennan and Dr. Shrum give results showing that they have been able to reproduce the same luminescence effect in solid nitrogen which I discovered in January last and foretold in my earlier papers on the auroral spectrum. In their discussion of the results, however, they come to the conclusion that this effect is not applicable to the auroral spectrum.

In order to meet the argument put forward it would indeed be sufficient to refer to my previous publications,[1] from which it appears that the conclusions drawn by McLennan and Shrum are contrary to observed facts; but as their paper might give the impression that they had found new facts which disproves my interpretation of the auroral spectrum, and as their paper also, in my view, contains some other errors, a few comments upon it seem to be necessary.

First of all, it should be made clear that our difference of opinion does not originate from a difference with regard to experimental facts. As already mentioned in my previous papers, the luminescence of solid nitrogen shows two bands in the green, called N_1 and N_2. While N_2 has the appearance of a single diffuse line, N_1 has the form of a band showing three maxima, one strong ($\lambda = 5555$) and two weak ($\lambda\lambda = 5611$, 5649). McLennan and Shrum find the same two bands and with the same structure. For the three maxima of N_1 they give the wave-lengths 5556, 5617, 5654, in good agreement of my own values. The band N_1 extends on both sides of the auroral line (5577); but this line does not coincide with any of the maxima of the band N_1.

Now McLennan and Shrum *regard the three maxima of the band N_1 as ordinary spectral lines with a definite wave-length*, and, as the auroral line does not coincide with any of them, they regard it as proved that the band N_1 has nothing to do with the auroral line. The matter, however, is not so simple, and these two investigators do not seem to have realised that we are dealing with a light effect of a peculiar type. Their conclusion, which usually would hold for spectral lines originating from a gaseous source, is not valid for the light effect in question, which is emitted from matter in the solid state.

As a matter of fact, I have been able to show that this light effect is attached to some special crystal structure of nitrogen and that *the maxima of the band N_1 have no definite positions, and hence they cannot, as is done by McLennan and Shrum, be treated as ordinary spectral lines.*

My view is that the band N_1 is a manifestation of the same effect as that which is responsible for the auroral line, which is to be regarded as the limiting aspect of this band when the particles are reduced to molecular order of magnitude. The correctness of this view is strongly supported by the results of my experiments with mixtures of nitrogen and argon.

So long as we are unable to reproduce the conditions of the upper atmosphere, we cannot apply to the band N_1 the ordinary spectroscopic method of identification by means of exact wave-length measurements. It is possible, however, to test the correctness of my view by taking into account the whole auroral spectrum and by drawing evidence from the various cosmic phenomena connected with the upper atmosphere, and—as will be seen from my papers—my conviction of the correctness of my interpretation of the auroral spectrum is gained in this way.

In dealing with the auroral spectrum we must, above all, take into account the type and the intensity distribution of the lines. The error which we find in so many earlier attempts at interpretation is that due attention has not been paid to the *spectrum as a whole*. In spectral tables a number of lines were found, which, within the limits of possible errors, coincided with auroral lines, regardless of the question as to whether the lines so picked out formed a connected physical system and could exist as a light effect from one single source. We should not only consider the lines which actually appear in the auroral spectrum, but also regard those, often equally important, which *are not present*. Now solid nitrogen bombarded with cathode rays constitutes a simple physical system which just gives the most singular type of spectrum which is found for the auroræ, and also explains the predominance of the auroral line. McLennan and Shrum suggest that the experiments show that N_2 ought to come out stronger in the auroral spectrum than it actually does. This, however, is not so, for, as my experiments show, N_1 may be made to dominate the whole spectrum, and, under the conditions existing in the upper atmosphere, we should from my experiments expect the auroral line 5577 to be quite predominant as compared with 5230.

McLennan and Shrum are also mistaken in regard to their interpretation of the luminescence from solid argon. Thus their statement that they have found a phosphorescence with an afterglow in pure argon is not in accordance with my experiments. The green afterglow usually observed was shown to be due to minute traces of nitrogen, and the phosphorescence line was identical with N_2. Further, they regard the strong diffuse line 5607 as an argon line; but this line is no doubt the same as 5604 of my experiments, and this line was shown to be the N_1 band of nitrogen in a somewhat different position and in a transformed state. The correctness of my view was evident from the analysis of the light effect from mixtures of argon and nitrogen of varying concentrations.

Also the view taken by McLennan and Shrum with regard to the physical conditions for producing the N_1 band is contrary to my observations, details of which will be found in my papers.

In conclusion, it is perhaps worth while to suggest that differences between McLennan and Shrum's observations and my own may be partly due to the fact that their experimental material was very limited, and that their arrangements made it difficult to overlook the experimental conditions and to vary them in a known way. Instead of bombarding a layer of solidified gas with a well-defined bundle of electric rays—as was done in my experiments—they have formed the layer on the walls of the discharge tube itself, which was wholly surrounded with the cooling liquid.

Interpretations of Primitive American Decorative Art.

My friend Mr. G. C. Robson, the gifted malacologist of the British Museum (Natural History), has taken me to task in NATURE of September 13 over the interpretation of the Mayan sculptures which I ventured to make in the issue of August 2. Writing as a zoologist he has censured my communication more leniently than I should have done were I criticising it from the same point of view.

Mr. Robson avers that I am inaccurate in stating that in the argonaut and the Bathypolypus the two central arms are often so closely apposed as to appear a single very broad tentacle. During the writing of my communication (in April last) I examined and roughly sketched, both in the Reading Room and in the Mollusca Gallery of the British Museum, drawings and specimens of various Cephalopoda. I am to my regret unfortunately unable to give him, as I should like, specific references to these sources of information, as they have been destroyed, and being now invalided to my room, I am precluded from visiting London to re-examine them. Mr. Edge-Partington, however, well known for his album of primitive decorative art, with whom I have throughout discussed this question, agreed with me in seeing in my memoranda a broad trunk-like tentacle by the apposition of two others. If memory serves, my note on the argonaut was made in Mr. Robson's gallery at South Kensington. I am not a malacologist, and my assignation of the tentacles to a "central" position is doubtless (since Mr. Robson says so) morphologically inaccurate; but that has little or no bearing on the identification of the *motif*.

Mr. Robson nevertheless admits that the Manabi slab "looks like a conventionalised squid," but he asks: If a squid, why eight arms? And what is the meaning of the tufts on the mantle and of the circular ends of the arms? My friend has gone astray in looking too malacologically at these Mayan designs. He forgets that the Central American sculptor did not work on a zoological subject for exhibition at the R.A., or for a scientific diagram. He was a *decorative* artist with extensive spaces to adorn, while his chief aim was to depict gods of terrifying aspect.

I remember well, when a boy, searching on a beach of the North Sea for upcast treasures after a gale, the finding of a creature unknown to me, whose enormous immobile eyes and long arms studded with suckers made a lasting impression on me, and especially my astonishment when, on dissecting it, a parrot's beak was prominently disclosed which I concluded the creature had choked upon! If I were now, after sixty years, asked to sketch my recollection of this "cuttle-fish," the serpent-bird panel from Tikal (Fig. 2 of my letter August 2) would closely fit my impression of my first cephalopod. The Mayan sculptor had perhaps recalled, in his work, a vivid and more terrifying experience with one or other of the monsters of this family, or he may not improbably have worked on lines handed down to him from ancestor artists who knew such a creature too intimately.

In my letter of August 2, in trying to look at the sculptures through the Mayan artist's eyes, I made suggestions as to features of more than one cephalopod family to fix the true basis of his *motif*. None of the Mayan designs represents any one species, but here one and there another suggestion from different groups seems incorporated in the artist's scheme, but the *motif* of them all—not only of those I alluded to in my letter, but of numerous decorative designs on structures, to which space did not allow me to allude on August 2, throughout ancient Mexico—is in my opinion based on members of the Cephalopoda, incorporating likely enough the indigenous parrot, but none based on elephant trunks. The sculptor had to get in what impressed him most—eyes, tentacles, and especially prehensile suckers.

In the decorative craftsman's method of work it is of no consequence whether the arms are of the proper number, or the eyes, mouth, or suckers are anatomically correct as to position. He relied in his work on a "most generalised conception" as all primitive decorative artists do. He was not tied to anatomical details; he took from or added to his mental prepossessions as suited his space and his caprice; realism meant nothing to him. May I recall to Mr. Robson the frigate-bird design in New Guinea. "One may see designs," as Mr. Henry Balfour very aptly words it (*Journal Soc. Arts*, 1896), "representing the frigate-bird in all stages between very fair realism and complete conventionalism—tending towards a purely meaningless pattern whose resemblance to a natural object has entirely ceased. . . . *The tendency is for the more important portions of a symbolic design to persist while the rest may disappear*" (my italics).

A still more suggestive example is that figured by Mr. Edge-Partington in *Man* (1902, 17), where a lizard (or other animal) is carved realistically moving on its legs with its tail coiled in a spiral; but later we find the design on a large panel degenerated to a conglomeration of spirals overspreading it, and wherever a vacant space—so abhorred by decorative artists—occurs too small for spirals, it is filled in by an endless series of the animal's legs. The cephalopod design in Mexican decorative art—of the Stela B period—was approaching the same stage as these frigate-bird and lizard designs. The tentacles and suckers—the most important portions of the symbolism—were repeated wherever they could be inserted. The Mayan artist, however, did not, as Mr. Robson suggests, throw "the structure of his model entirely to the winds," for the designs in the lower register at each corner of Fig. 3 (letter of August 2)—which of course is only half the panel—and especially the design on the back of Stela B, Fig. 7, are realistic cephalopods which I leave Mr. Robson to name. What relation can they possibly have to an elephant, and why introduced if they have no relation to that *motif*? And why are the coiled arms on Stela B, regarded by Mr. Robson as "structures that look like a tusk [of an elephant]," provided with suckers?

If in April I had possessed Prof. Elliot-Smith's "Evolution of the Dragon," I could have condensed considerably my letter in NATURE of August 2 (which rather taxed the valuable space at the disposal of the Editor), for I could have cited the extraordinarily illuminating figures (23, p. 172, and 24, p. 180) in that volume for pictorial support to my theme. In these pictures Mycenæan and Ægean potters, doubtless impressed, as were the American sculptors, with the staring eyes and the cusp-studded tentacles of cephalopods of their own seas, have pictured them in almost identically the same manner as the Copan sculptors have done. Mr. Robson will see there even circular ends to the octopus arms, about which he makes inquiry. He should also compare my Fig. 7 (August 2) with Elliot-Smith's Fig. 23 (*op. cit.*). "The position usually adopted by the resting octopus" which that author reproduces (after Tryon) on Fig. 22 supplies speaking suggestions for the cusp-studded tentacles surrounding the top of Stela B, of which two to fill suitably its front top edges, recalled from some gigantic species of the western seas, have been too confidently assumed to be elephant trunks.

Elliot-Smith's plates, 23 and 24, are interesting
fm another point of view. The Mediterranean
a ists have employed a strikingly similar method of
r esenting the octopus as the Mayan quite *inde-*
endently of each other, and at two far separated
l alities. This fact gravely invalidates the moral
p nted by the dogmatic sermons of Prof. Elliot-
S ith and his disciples, if I understand them, that
v thout contact no two minds have ever independ-
e tly "brought forth similar products whether in
s ial organisation, religion, or material culture."
] Egypt "and nowhere else" did inventions
o ginate! It is surprising that with his own plate
b before his eyes Prof. Elliot-Smith failed to recognise
t e clue to the riddle of the Mayan indigenous sym-
l lism, but wildly stumbled on so exotic a *motif* as
a mahouted elephant's trunk in America.

HENRY O. FORBES.

Active Nitrogen.

PROF. R. T. BIRGE states in his letter appearing in
NATURE of November 1, p. 642, that "active nitrogen
was discovered in 1900 by Prof. E. P. Lewis, . . . and
was found by him to have a characteristic spectrum."
I dislike discussions about priority, but can scarcely
avoid pointing out that the expression "Active
Nitrogen" was coined by me to express the facts
which I discovered in 1911—namely, that a stream
of nitrogen in a peculiar state is able to react in the
cold with certain metals to produce nitrides, with
carbon compounds to form hydrocyanic acid, and so
on. This was established by purely chemical methods.
The luminous phenomena which gave the clue to this
discovery were described by Prof. E. P. Lewis, and I
was careful to make due reference to his work.

RAYLEIGH.

November 5.

The Mass-spectra of Cadmium, Tellurium, and Bismuth.

I HAVE now succeeded in obtaining and analysing
the mass-rays of cadmium, tellurium, and bismuth.
By the use of an anode containing cadmium fluoride,
rays were obtained which, though feeble, gave satis-
factory results with long exposures and the most
highly sensitised schumannised plates. Cadmium is
a very complex element, having six isotopes: 110 (c),
111 (e), 112 (b), 113 (d), 114 (a), 116 (f). The last is
isobaric with the lightest isotope of tin. The in-
tensities of the lines are in the order of the letters
and agree reasonably with the chemical atomic weight
112·41. The most striking characteristic of the group
is its remarkable similarity to that of tin. If we
except the heaviest isotope of tin (124), which does
not seem to have its counterpart in cadmium, the
intensity relations between the isotopes of the two
elements appear almost identical. This is a most
suggestive fact and may have a deep significance in
connexion with the relative stability of the nuclei of
isotopes. The plates are not very favourable for
accurate determinations of masses, but these seem
integral with that of iodine.

The line of the latter element was extremely faint
in these experiments, so I considered it a favourable
opportunity to make another attempt on tellurium,
which had defied all attacks during the earlier dis-
charge tube work. A little pure metallic tellurium
was ground into the anode mixture and success was
at once obtained. Tellurium gives three lines of
mass numbers—126, 128, 130. The intensities of the
two latter appear about equal and double that of the
first. I have repeated this result with an anode
containing tellurium and lithium fluoride, and have
no reason to doubt that these are all genuine isotopes.
Comparison with other lines on the plates suggests
that their masses may be less than whole numbers by
one or two parts in a thousand, but it seems probable
that the mean atomic weight is actually greater than
128, whereas all the later chemical determinations
are less than that figure, the accepted value being
127·5. The element tellurium is unique among those
so far analysed, as it seems probable that *all* its mass-
numbers form members of isobaric pairs. These are
shared by xenon, the element of next higher even
atomic number.

The boiling-point of tellurium is not very different
from that of bismuth, so that it seemed possible that
the latter might yield to the same treatment. This
hope was realised with an anode containing metallic
bismuth, and a single line appeared in the expected
position—209. This line is very faint, and owing to
the great mass lies in an unfavourable part of the
plate, but there seems no reason to doubt that
bismuth is a simple element of mass number 209, as
recent determinations of its atomic weight suggest.

November 4.

Need for the Redetermination of the Atomic Weights of Uranium, Thorium, and Radium.

IT is known that the atomic weights of such radio-
elements as have been determined experimentally
agree approximately with those to be expected on
radioactive theory, and also that small unexplained
discrepancies appear when the actual instead of the
approximate values are considered. The simplest
explanation of these small discrepancies is, I think,
that one at least of these determinations is wrong,
and I give reasons below for this view in the hope
that someone versed in atomic weight work will
make fresh determinations of the masses of the
elements concerned.

The following are the experimental values of the
atomic weights to be discussed: uranium, 238·18;
thorium, 232·15; radium, 225·97; radium Ω′,
206·04; thorium Ω, between 208·0 and 208·2. If
the atomic weight of radium Ω′ be accepted as 206·04,
that of radium should be 226·08 and that of uranium
238·09, assuming that the α-particle has a mass of
4·00, and allowing for the loss of mass due to the
energy of the expelled particles. Each of these
values is nearly 0·1 different from the experimental
values. If the allowance for the loss of mass be
neglected, the calculated value for radium is within
the error of the experimental value, but the calculated
value for uranium is 0·14 smaller than the experi-
mental. Several workers, including the writer, have
preferred to accept this second view and to explain
the discrepancy between uranium's calculated and
experimental values by assuming the existence of an
isotope with a greater mass than that of uranium.
The new contribution to this discussion is that this
will not account for the discrepancy. Such an isotope
would reveal itself by its product, and it is now known
that the experimental evidence, while favouring the
existence of this isotope, is against its concentration
in ordinary uranium to an extent that would raise
the mean atomic weight more than 0·03. The close
relation between groups of radioactive isotopes and
those of inactive elements, lately pointed out by the
writer, leads also to this view. It would therefore

appear that if uranium's atomic weight is 238·18 the mass of uranium 1 is at least 238·15. This implies that in the transformations between uranium 1 and radium Ω′ a mass of 0·11 is lost in addition to the mass of the eight α-particles expelled. Whatever be the reason for this, it is probable that this small mass would be lost gradually, *i.e.* that ionium's mass would be about 230·13, radium's mass 226·11, and so on. This suggested value of radium's mass is greater than the experimental value by 0·14.

If the atomic weight of thorium is 232·15, this is also the actual mass of the radioelement thorium, for any existing or possible isotopes of greater mass-number are or would be β-ray bodies, and therefore of periods so short that their concentration in ordinary thorium could not affect measurably the mass of the principal constituent. The work of Prof. Joly on thorium haloes established in 1917 the absence of any very long-lived isotope of thorium, and confirms from an independent source this view. On present atomic weight evidence, then, there appear to be two bodies the masses of which are in excess of integers by about 0·15. So far mass-numbers in excess of integers have not been found by Dr. Aston among inactive elements. The mass of thorium Ω is uncertain to about 0·2, owing to the fact that no pure specimen of this isotope has yet been isolated.

The value of thorium's mass need have no bearing on those of uranium and radium, since thorium is a member of an independent series, unless we choose to assume that the rule discovered by Dr. Aston for the isotopes of several elements and, in particular, for those of tin, applies to the radioelements also. This rule is that differences in the masses of isotopes are approximately integral even when the masses themselves are not. Applied to thorium and ionium, it suggests the latter's mass is 230·15 if the former's mass is 232·15. This leads to masses of 238·15 and 226·15 for uranium and radium respectively. The former is within the experimental error of the accepted atomic weight, the latter is 0·18 too high.

It is, of course, obvious that there are too many uncertain factors at present to justify basing any conclusions upon these small differences. But there is a *prima facie* case, I hope I have shown, for the need of a redetermination of the atomic weights of uranium, radium, and thorium.

A New Drift Indicator.

In connexion with research on fishery problems many investigations have been undertaken to throw light upon the water movements in the North Sea and other areas.

Schematic pictures of the current regime have been obtained in various ways, for example, by studying the isohalines of salinity distribution charts, by making direct observations of the currents by means of various instruments (current-meters, log-ships, etc.), and by setting adrift floating objects and noting where they are recovered. Each method has its obvious merits and demerits, but, when all things are considered, the use of drifting objects (usually bottles containing questionnaire papers) yields, without doubt, the most useful results for the purposes of those engaged in fishery research. The bottles are put out at a selected position, and the charting of the places where they are recovered is a relatively simple matter. The information obtained is very valuable, but it does not give the actual set away from the position of liberation.

Attempts to estimate this by means of current meter observations necessitate the computation of the residual current after the elimination of the tidal stream values from the observational data, and, in order to obtain any trustworthy knowledge of the residual currents as a result of direct measurements, considerable amount of data is absolutely necessary. Moreover, the resulting calculations are very laborious —at any rate this is the case with any instrument known to me.

An attempt has recently been made at this laboratory to devise an instrument which will yield the necessary information as to residual currents without exhaustively intensive measurements or laborious calculations. The instrument combines certain features of the well-known Ekman current meter with others of the Robinson anemometer (Fig. 1).

A set of cups which rotate when the instrument is lowered into the sea, are connected through certain gearings with an arrangement which releases phosphor bronze balls from a hopper, and allows the balls to roll down a groove on a specially shaped pivoted

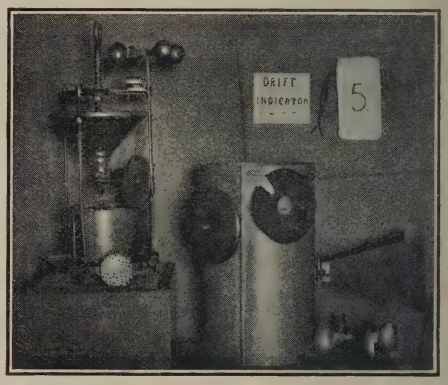

Fig. 1.—Drift indicator. To ensure that the instrument shall remain vertical when suspended in a tideway, the vanes are now shipped at the top of the cover and their after end is provided with an inclinable plane which enables the desired object to be effected.

magnet and so into a divided chamber. This chamber during the course of observations is orientated according to the current—the whole instrument being kept "in the current" by means of a vane on the cylinder which encloses the working parts. The hopper may hold many thousands of balls. The instrument which has been tested has been found to use about 700-800 balls per diem.

I am indebted to the Elder Brethren of the Trinity Corporation and to their Superintendent of the Great Yarmouth depot (Capt. G. T. Thompson) for the opportunity of carrying out the necessary tests on the St. Nicholas light-vessel which is situated about 1¼ miles off Great Yarmouth. The instrument can be worked quite well by the personnel of a light-vessel, and the results given below were obtained when the indicator was left down for 24 hours in the charge of the mate of the lightship named (Mr. T. Jay).

The sectors in the divided compartment (Fig. 2) are 20°, and the figures denote the numbers of balls in the various sectors.

The use of ordinary traverse tables enables one easily to resolve the values (numbers of balls) along the four cardinal directions and to find the magnitude and direction of the residual current if the "mileage value" of the balls be known. Calibration against log-ship observations showed that 24 balls were dropped for each mile of water that passed the ship. The necessary calibration was not an easy

natter at the time of the test. The movements of the ship at the time were not such as would allow the instrument to be kept near the surface without the risk of it being over-ridden and damaged. It was therefore used at a depth of about 7 fathoms. The log-ship time gave the rate of the surface stream, which rate was assumed to be also that of the water at 7 fathoms depth (though only pending further opportunities of testing the instrument near the surface).

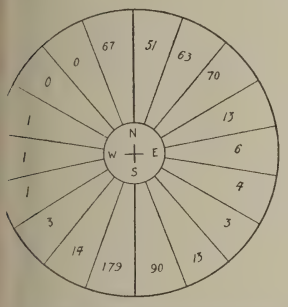

FIG. 2.—The distribution of balls in the compass box after a test of 24 hours ending 10.25 A.M., October 18, 1924.

Since the rate at the depth worked is certainly less than at the surface, it follows that the conversion factor used (24 balls per mile) is too low, and that the magnitude of the residual current calculated is too high, although the direction is correct.

The above data yield the following approximate maximal value for the residual water movement or drift :

$\frac{1}{2}$ miles per 24 hours in the direction S *ca.* 50° E. mag.

This drift indicator can be adapted to drop balls with varying frequency, and it can be left down for any length of time depending upon the size of the hopper chosen. Improvements in shape and size are to be carried out, and it is hoped that it will be possible to add considerably to our present knowledge of the water movements in areas of interest.

The Resonance Theory of Hearing.

IN reference to the recent letters of Prof. Scripture and Mr. J. Keen which have appeared in NATURE under the above heading, it seems to me that the opponents of the resonance theory rely rather too much on the assumed inherent absurdity of the theory. It is a theory which has been, and is, held by a considerable number of people whose judgment in the matter is deserving of, at all events, some consideration.

In drawing analogies from the other sense organs, Mr. Keen should bear in mind that the nature of the analysis required of them to furnish accurate information to the brain is different for each sense. To say that the retina does not analyse white light into its constituent colours is to assert what is by no means proved. It is certainly true (fortunately for our vision) that the retina does not separate these constituents of white light spacially, but that an analysis of the waves of light according to frequencies does occur is an assumption essential for the explanation of colour vision. It is generally believed that this analysis takes place in the retina and not in the brain. The analogies between tone analysis by resonance and colour vision may indeed be carried much further.

Mr. Keen's example of the senses of heat and cold seems scarcely applicable. Here temperature represents intensity, and is perceived as such. Intensity is, of course, an attribute of all sensation.

The recognition of the basilar membrane as a resonating organ is based on the regular gradation of the differentiation of its parts for length, tension, and mass, between very wide limits. So marked is this gradation, that there is no inherent absurdity in the belief that it is sufficient to account for a range of action corresponding to the audible scale, say eleven octaves. The elaboration of this differentiation is unexplained either by the telephone or the pressure pattern theory. Indeed, the differentiation that one recognises in the cochlea is sufficient to preclude entirely the possibility of such "simple" modes of action. It is better to explain the function of an organ in terms of what is actually present than to devise theories as to how it may act in spite of what is known of its structure. GEORGE WILKINSON.

Polarised Light and Starch Content of Plants.

NEARLY two years ago (NATURE, January 13, 1923, p. 49) I was able to describe the acceleration of hydrolysis of starch under polarised light *in vitro*. It may be of interest to record that I have succeeded in confirming these results in the living plant.

Under artificially polarised light, the starch in the plastids, both in the guard-cells and in the leaf-tissue, has been shown to diminish, and the appearance in its place of a reducing substance has been demonstrated. In ordinary sunlight the starch content was increased, and in darkness the quantity remained unchanged. It is hoped to publish a full account of these experiments in the near future.

I wish to express my thanks to Prof. Neilson Jones, and to Prof. Lloyd, of McGill University, for helpful advice and criticism; also to the latter for kindly placing the facilities of his Botanical Department at my service, thus enabling me to benefit by the blue skies of Canada.

The Forces which lift Aeroplanes.

PROF. BJERKNES, in his Royal Institution lecture (NATURE, September 27, p. 472; October 4, p. 508), introduces the phenomenon of "acoustic repulsion" before going on to the accepted circulation theory of aeroplane lift. Both these are discussed in Rayleigh's "Collected Papers," Nos. 52 and 53 respectively; "Note on Acoustic Repulsion" (*Phil. Mag.*, 1878, also 1902, 1905), and "On the irregular Flight of a Tennis Ball" (*Mess. of Maths.*, 1877).

The former paper shows that the mean pressure in the interior of the cavity of a resonator is in excess of the external atmospheric pressure by the essentially positive quantity $(2\gamma t)^{-1}\int(p_1/p_0-1)^2dt$. The latter establishes, for the first time, the relation, Lift = Circulation × Velocity, a quantity which may be either positive or negative.

There does not seem to be any very close analogy between the two phenomena. A. R. LOW.

London, October 25.

The Technique of Contraception.

I VERY much value the discriminating and appreciative review by Sir Archdall Reid in NATURE of October 25, p. 601, of my book "Contraception (Birth Control), its Theory, History and Practice."

About the general technique of contraception, Sir Archdall is so kind as to say: "Dr. Stopes's experience . . . is so extensive that her opinions must necessarily carry weight." For this reason I must beg the courtesy of your space to correct his criticism that my views on cervical interlocking are a "belief." On the contrary, they are based on direct observation at the Clinic of more than forty cases. Further details will be given in the report on the first five thousand cases at the Clinic, which we are at present preparing. MARIE C. STOPES.

Givons Grove, Leatherhead, Surrey,
November 6.

Dust in the Atmosphere.

IT is to be hoped that the publication last year of the collected works of John Aitken has led many physicists to renew their acquaintance with his writings. The main features of his work are widely known, but it is not so generally recognised that on a number of points which are still obscure, he has many suggestive observations. In 1880, without knowledge of the earlier work of Coulier, Aitken discovered the nuclei of cloudy condensation in the atmosphere. For nearly forty years he continued to make observations on these nuclei, which he generally referred to as "dust." He devised and constructed various forms of dust-counter,

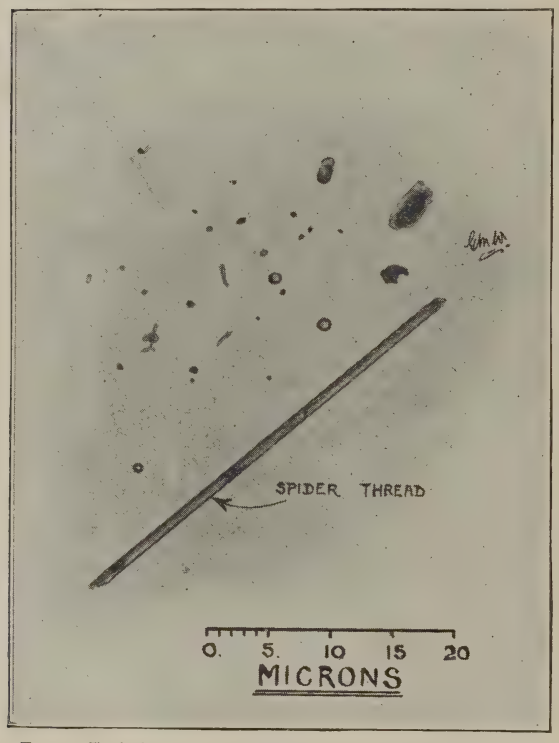

FIG. 1.—Typical smoke fog particles compared with a portion of an ordinary spider's web.

Reproduced, by permission of the Controller of H.M. Stationery Office, from the Ninth Report of the Committee for the Investigation of Atmospheric Pollution.

all characterised by ingenuity and mechanical skill of a high order, but most of them somewhat difficult of successful operation by any but the expert hand of the inventor. In his later years, writers on "large ions" caused him some uneasiness. He feared that the rôle of nuclei of cloudy condensation was being taken from his dust particles and attributed to some bodies of an electrical origin. But this fear was unfounded; what was suggested was that a certain number of Aitken's nuclei are charged and that these are the large atmospheric ions discovered by Langevin.

If this identification is correct, and it can scarcely be doubted, then we possess a considerable amount of information about Aitken's nuclei. His own work gives copious observations of the number of these bodies found under different conditions, while the experiments on large ions give us some clue as to their form and constitution. We may first note the very high values for the concentration of nuclei found by Aitken. In cities such as London, Paris, and Glasgow he obtained values of the order of 100,000 to 400,000 particles per c.c. In the pure air of the Scottish Highlands and in Switzerland his values frequently came down to a few hundred per c.c., but even on the Rigi Kulm he has observations of more than 15,000. The electrical observations on large ions suggest that the particles are, for the most part, of uniform size. If it be assumed that in the atmosphere each nucleus does not normally carry more than one electronic charge, and there is good reason for believing that this assumption is correct, then the diameter of the nucleus should be about 10^{-5} cm. The great numbers in which these bodies are found, their small and regular size, and the fact that they are produced so copiously from such a source as a Bunsen flame, suggest that they are not dust in the ordinary sense, that is, not irregular fragments of solid matter. Their behaviour and the manner in which they are produced indicate rather that they are spherules of water, each formed about some kind of primary nucleus, very often of a hygroscopic character. Assuming that the greater number of Aitken's nuclei are so constituted, in what form does the grosser mechanical impurity exist in the atmosphere? The answer will be found in the very interesting report of the Advisory Committee on Atmospheric Pollution referred to below.[1]

Three methods of estimating atmospheric impurity, representing successive stages in the development and improvement of methods of observation, have been employed by the Committee. In the method longest in use, the material precipitated by rain or otherwise on a standard area is collected. The monthly deposit is measured and analysed as soluble and insoluble, tarry, carbonaceous, sulphate, chloride, etc. The original gauges employed for this purpose were made of enamelled iron and did not prove resistant to atmospheric action. A new pattern constructed of stoneware has been employed and found satisfactory. It appears from the report that in the year which ended on March 31, 1923, there was a distinct improvement in the purity of the atmosphere as compared with the average of previous years. At 23 stations out of 27, the total solid deposited was lower than the normal, while the rainfall on the whole was about average. It is interesting to note that, comparing the deposit of chlorine in summer and winter, 19 stations show a higher figure for winter. This is in accordance with the view that the chlorine in the atmosphere is derived from sea-spray, the rougher seas in winter furnishing greater quantities of spray.

In the second method of observation, an automatic record is obtained on a sheet of filter-paper of the dusty impurity of the air by Dr. Owens' apparatus. From two to four samples of dust can be obtained per hour, and thus the variation in the impurity of the air can be followed through the twenty-four hours.

[1] Meteorological Office: Air Ministry. Advisory Committee on Atmospheric Pollution. Report on Observations in the Year ending March 31st, 1923: Forming the Ninth Report of the Committee for the Investigation of Atmospheric Pollution. (M.O. 260.) Pp. 59. (London: H.M. Stationery Office, 1924.) 4s. 6d. net.

Some striking records are obtained by means of this instrument. At night the air is very pure. In the early morning, earlier in summer than in winter, the

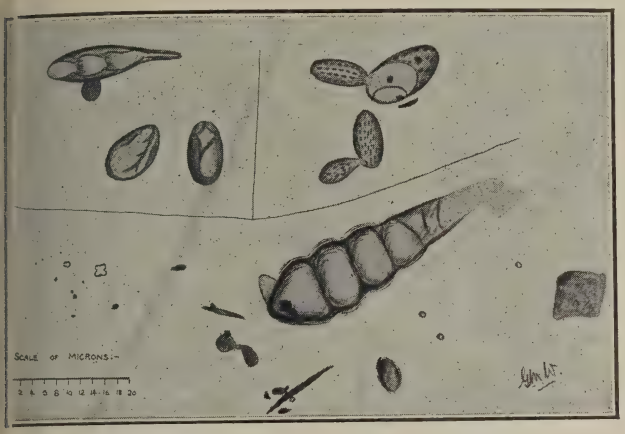

FIG. 2.—Organic particles of definite structure, collected from the air of Cheam, Surrey, on January 29, 1923, by means of the jet instrument. Reproduced, by permission of the Controller of H.M. Stationery Office, from the Ninth Report of the Committee for the Investigation of Atmospheric Pollution.

pollution recorded at the London stations increases rapidly, maintains a fairly high figure during the day with indications of a subsidiary minimum about 9 o'clock, and then falls off in the late afternoon. Here we note a distinct difference between the true dust and the Aitken nuclei. It does not appear that either Aitken or Barus, who did much work on the subject in America, took records of nucleation during the night. But it is clear from the observations of M'Clelland and Kennedy in Dublin that the large ions, that is, the charged fraction of the nuclei, are not noticeably fewer at night than during the day. Apparently the relatively large particles of true dust coagulate rapidly and are quickly deposited. The nuclei of Aitken are more persistent, but it is nevertheless surprising that, when their production has ceased, and when the air is being renewed rapidly on windy nights, they should not show a marked decrease. The dustiness shown by the automatic recorders in London is greater in winter than in summer and greater on foggy than on clear days. While in summer the atmosphere is cleaner on Sunday than on other days, there is no difference during the winter. The inference is that the greater part of the pollution in London is due to ordinary domestic fires. The same result is found to hold for the residential districts of Glasgow.

Much the most interesting part of this report is the record of results obtained with the jet dust counter. With this apparatus, the impurity in a limited quantity of air, say 50 c.c., is thrown on a glass slide, where the particles may be counted and scrutinised microscopically. The dust consists largely of irregular particles of a crystalline character, but occasionally organic bodies of a definite structure are found. A good idea of the appearance of the dust may be gathered from the illustrations, some of which are here reproduced (Figs. 1-3). The particles are of various sizes from 1 or 2μ down to the limit of visibility. A puzzling feature of some of the samples obtained has been the presence of transparent spherical bodies, for the origin of which no satisfactory explanation has as yet been obtained. Crystals of sodium chloride have been found in the air near the sea-shore, and other hygroscopic crystals have occasionally been recorded. The total number of particles found is surprisingly large considering the character of the material, but small compared with the number of nuclei found by Aitken. For example, an average figure for London would be about 10,000 dust particles per c.c. The average number of condensation nuclei is about ten times this figure. If the ultra-microscope could be employed, as has been done with success in the examination of smokes, no doubt a considerable number of particles which are beyond the optical limits of the present method would be detected. But as, according to de Broglie, the ultra-microscope fails to show up the large ions, we can scarcely anticipate that any optical method will disclose the bulk of Aitken's nuclei.

Now it is not at all clear that the Aitken nuclei may not have effects in some respects more important than those of the visible nuclei. For example, the connexion between the concentration of nuclei and haze was pointed out by Aitken. Some part of the reduction in visibility in polluted air may be due to scattering by the large

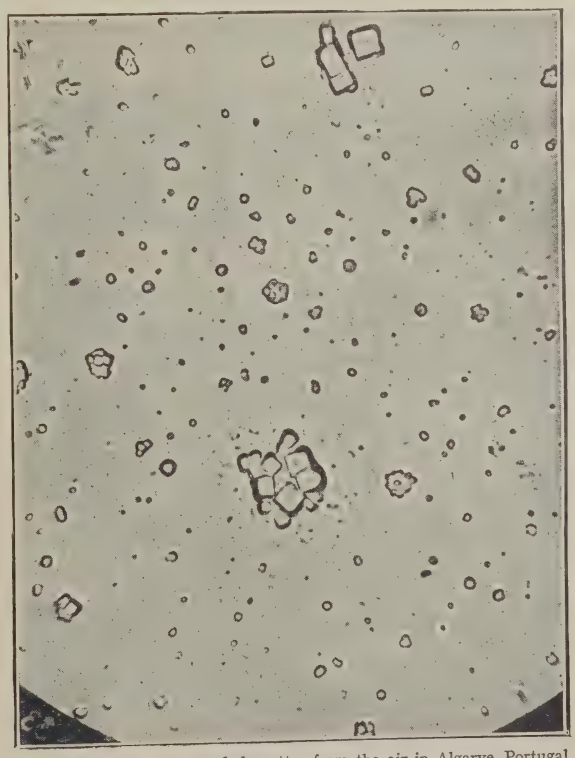

FIG. 3.—Record of suspended matter from the air in Algarve, Portugal, taken on a hot, sunny day. The particles consist mainly of crystals of common salt. Photograph. Magnification 1000 diameters. Reproduced, by permission of the Controller of H.M. Stationery Office, from the Ninth Report of the Committee for the Investigation of Atmospheric Pollution.

numbers of nuclei. Again, in the phenomena of atmospheric electricity dealt with recently in these

pages by Dr. Chree and others, the nuclei, owing to their large numbers, have possibly a greater effect than the visible particles.

The effect of impure air on visibility has been investigated by the Committee and two photometric methods of measuring the obstructive power of polluted air have been perfected. Approximate proportionality has been established between the light obstruction and the quantity of pollution present as measured by the filter and jet methods. But the Committee finds that "some factor other than the simple obstruction of area of the light source is responsible for the loss of light in passing through the air." It might elucidate this point and help to a fuller examination of the whole problem of contaminated air if observations of the total condensation nuclei were taken after the manner of Aitken. It would be unsafe to assume a proportionality between the visible dust and the nuclei. Many sources of large particles may yield few nuclei and certain rich sources of nuclei, Bunsen flames, for example, may be expected to give few large particles. In this connexion the writer noticed some months ago that during a three weeks' gas-strike in Dublin, the number of large ions was much below the normal. Irregular variations are so common that it may be difficult to decide if the reduction is a genuine effect unless a further opportunity for investigation—otherwise undesirable—should present itself. The Committee has already achieved such a high level of success in the development of methods of observation and in the perfecting of instruments that if it can be induced to undertake the observation of condensation nuclei, those of us who are interested in atmospheric nucleation may expect to see instruments developed of a far higher standard of efficiency than those available at present.

It should be stated that the automatic dust-recorder and the jet dust counter are now in use in many countries. They are available for purchase, and full instructions for their operation can be obtained. There is no doubt that they will prove of great value in dealing with a multitude of problems relating to impure air.

The chief evil of a polluted atmosphere is not the æsthetic horror of the smoke canopy, the grimy buildings and the stunted vegetation. It is not even the inspiration of dirty air—and we learn from this report that in the course of twenty-four hours of a heavy smoke fog, the dweller in London breathes in 500,000,000,000 particles of suspended matter. The real crime is the cutting off of sunlight. We have yet to learn in detail how the impure atmosphere of cities operates to abstract those elements in sunlight which appear to be necessary for health, and we have yet to test the possibility of minimising the evil. Meanwhile it is to be hoped that the Committee on Atmospheric Pollution may be enabled to extend and develop the fruitful work it has undertaken.

J. J. NOLAN.

The "Terrella."

THE name "Terrella" appears to have been first used towards the end of the sixteenth century to describe a sphere of loadstone used as a miniature replica of the earth for the study of terrestrial magnetism. Seventeenth century writers mention terrellas fairly frequently but there are not many descriptions of particular specimens, and although considerable numbers must have been in use during the seventeenth century, very few indeed appear to have survived. Rounded loadstones had been used from very early days. Peregrinus, for example, in the thirteenth century, mentions a method of making them and of finding the poles, but he does not give any particular scientific use to which they could be turned.

It was not until Gilbert of Colchester, in the prosecution of his studies in magnetism, etc., found that a miniature of the globe constructed of a suitable piece of magnetic ore would be of great assistance in his researches, that the rounded loadstone of earlier investigators was developed into a more or less scientific instrument. Dr. Gilbert, early in his great work "De Magnete" (1600), gives details for the manufacture of an instrument "Called by us a Terrella," this being described as a "physical Corpuscle imbued with many virtues by means of which many abstruse and neglected truths in philosophy burried in piteous darkness may more readily become known to men."

Many chapters of "De Magnete" are wholly devoted to details as to manufacture, graduation and the experimental use to be made of the finished article. Chapter XVII., Book II., giving details of methods of arming to "increase the virtue" of the instrument, is of special interest in connexion with the three specimens to be described. In order to show the opinion of his successors the following extract from Sir Kenelm Digby's (1644) "Two Treatises, on the Nature of Bodies: and, the Nature of the Man's Soule is looked into" will be of interest—

"But to come to some experimentall proofes and Obseruations on the loadstone by which it will appeare that these causes are well esteemed and applyed, we must be beholdin to that admirable searcher of the nature of the loadstone, Dr. Gilbert; by means of whom and of Dr. Haruey, our nation may claim euen in this latter age as deserued a crowne for solide Philosophicall learning as for many ages together it hath done formerly for acute and subtile Speculations in Diuinity. But before I fall to particulars, I thinke it worth warning my Reader, how this great man arriued to discover so much of Magneticall Philosophy; that he, likewise, if he be desirous to search into nature, may, by imitation, aduance his thoughts and knowledge that way. In short, then, all the knowledge he gott of this subject was by forming a little loadstone into the shape of the Earth. By which means he compasses a wonderful designe which was to make the whole globe of the earth maniable; for he found the properties of the whole earth in that little body; which he therefore called 'Terrella' or 'Little Earth'; and which he could manage and trye experiences vpon att his will. And, in like manner any man that hath an ayme to aduance much in naturall sciences, must endeavour to draw the matter he inquireth of, into some such modell, or some kinde of manageable methode; which he may turne and winde as he pleaseth. And then lett him be sure, if he hath a competent vnderstanding, that he will not misse of his marke."

The following references to definite instruments may be found in seventeenth-century records.

1. John Evelyn, July 1655, in his diary mentions a "pretty terrella with the circles and showing the magnetic deviations."

2. Pepys under October 2, 1662, states he "received a letter from Mr. Barlow with a Terrella."

FIG. 1.

3. A terrella, 4½ in. in diameter, was presented in 1662 by King Charles II. to the Royal Society.

4. In Grew's catalogue and description of the rarities belonging to the Royal Society, and preserved at Gresham College (London, 1681, p. 364), is mentioned a terrella contrived by Sir Christopher Wren with one half immersed in the centre of a plane horizontal table.

5. In Sir John Pettus's "Fleta Minor," London 1683, in the "Dictionary of Metallick Words" at the end, under the word "Loadstone" occurs the following paragraph:

"Another piece of curiosity I saw in the hands of Sir William Persal (since deceased also), viz. a Terrella or Loadstone, of little more than 6 in. diameter, turned into a Globular form, and all the imaginary lines of our Terrestrial Globe, exactly drawn upon it, viz. the Arctick and Antarctick circles, the two Tropics, the two Colures, the Zodiac and Meridian: and these lines, and the several countryes, artificially painted on it."

So far as can be ascertained, only three instruments which can be strictly included under the term "Terrella" can now be traced, and as all three are at present in the Admiralty Compass Department Museum at Ditton Park, a brief description of their characteristics and the little that is known of their history is possible.

1. *Compass Department Terrella.*—This is by far the most finished and efficient instrument of the three; in fact, it is the only one which might be termed a scientific instrument, and which carried out Gilbert's practice to the utmost. Its history prior to the early years of the nineteenth century is unknown, but then it hung as a curiosity in the shop window of the well-known compass makers, Messrs. Grant Preston, Barr Street, London, and is mentioned as being seen there in 1844. It came into the personal possession of Captain W. Mayes, R.N. (Superintendent of Compass Department), in 1887, and has remained in the Museum since that date.

General Description.—The instrument (Fig. 1) consists of three parts: (*a*) the terrella of highly magnetic ore 1·7 inch in diameter, (*b*) and (*c*) two brass hemispheres which when screwed together form the arming and casing. Great circles and parallels of latitude are engraved on both the sphere and its case, and a very special feature of the latter is the iron cap (⅓ inch in diameter) let into the north pole forming one piece with the projection inside; the efficiency of this arrangement in collecting the lines of force is obvious from the increased lift given below, and the results would probably be better if the pin and depression in the north pole of the terrella were not considerably worn and the fit therefore loose, and also if suitably designed weights were used. The small pin at the south pole appears to be simply intended to hold the sphere firmly in place. The terrella itself weighs 6⅜ oz., and unarmed lifts 1¾ oz.; with the case in place, however, this lift is increased to 9⅜ oz.

2. *Royal Society Terrella* (R.S. No. 80).—This is a roughly turned sphere of loadstone 4⅜ in. in diameter, and marked with a cross at each pole. No method of arming is provided. It weighs 7 lb. 2½ oz., and has a lift of 6 oz.

3. *Royal Society Terrella, 3 in.*—Sphere of loadstone (Fig. 2) slightly flattened at the south pole. Faint red markings show that meridians and equator have been roughly drawn. For "arming"—the sphere is loosely held between two iron cups joined by a silver bridge. It weighs 2 lb. 1½ oz., and lifts when armed, 3 oz.

The summary of all the available information past and present on particular instruments is remarkably meagre, and, when it is considered that many must have been in use during the seventeenth century, it is surprising that more specimens have not survived in museums and private collections; it is possible that the publication of this short article will result in bringing to light a few more of these interesting instruments.

Dr. Gilbert's work evidently aroused the interest of many of the great investigators of his time, and there appears to have arisen a demand for "armed" loadstones as scientific curiosities which fetched high

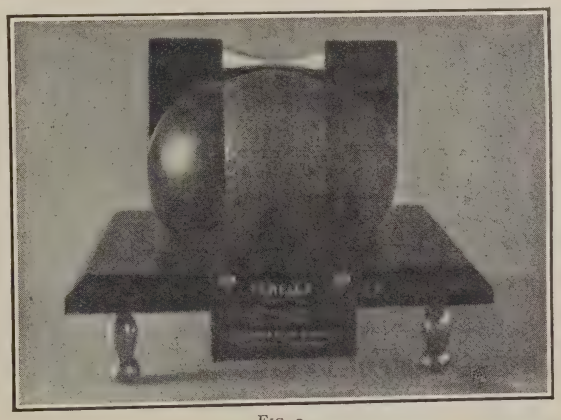

FIG. 2.

prices. Galileo especially brought their manufacture to a high pitch of perfection if the records of his achievements can be credited; his loadstones were not, however, terrellas, as is clear from the very interesting paper entitled "Galileo and Magnetism, a Study in Loadstones," by J. J. Fahie, published in the Journal of the Institution of Electrical Engineers, vol. 56, p. 246.

F. C.-O.

Obituary.

PROF. J. E. CREIGHTON.

NEWS reaches us from America of the death on October 8, after a long illness, of Prof. James Edwin Creighton, Sage professor of logic and metaphysic in Cornell University since 1895. The United States lose in him one of their most influential and deeply respected teachers. It is only a short time ago that Prof. Creighton's old pupils published a volume of essays in his honour. He was better known as a tutor and lecturer than as an author, though his "Introductory Logic" is widely used by students in Great Britain as well as in the United States. He was engaged on an important work, "The Rise of the Historical Method in Philosophy," when illness compelled him to set it aside. Outside his own university, he was widely known as editor of the *Philosophical Review*, one of the leading American journals devoted to philosophy, and representative of the idealist theories, also as American editor of "Kant-Studien."

Prof. Creighton was one of the founders of the American Philosophical Association, and its president in 1902 and 1903. He was a member of the permanent committee of the International Congresses of Philosophy and took great interest in the European meetings. It was one of his most ardent wishes to arrange an international meeting in the United States, and his death occurred just at the time when his Association is sending out its invitation to the VIth Congress to be held at an American University in 1926.

Prof. Creighton was born at Pictou, Nova Scotia, on April 8, 1861. He was educated at Dalhousie College, Halifax. The terrible explosion which occurred in that city during the War occasioned the loss of many friends and relatives, and he never completely recovered from the sorrow and shock which he suffered at that time. H. WILDON CARR.

WE learn with deep regret that Sir Archibald Geikie died on Monday, November 10, at the advanced age of eighty-eight years. The world of letters as well as that of science has thus lost a leader of the highest distinction, whose work has had a profound influence upon intellectual progress and the advancement of knowledge. A few months ago (NATURE, July 26) we published an appreciative survey of his activities in a review of his autobiography, and in our issue of January 5, 1893, his portrait appeared in the NATURE Series of Scientific Worthies, with a sketch of his career by Prof. A. de Lapparent. It is unnecessary to mention now his untiring activities in scientific fields or the many academic honours which came to him, but we are voicing the thought of the whole scientific world when we say that his death leaves a blank in the lives of all who are stimulated by human achievement.

WE regret to announce the following deaths:

M. L. E. Bertin, for many years director of naval construction in France, and an honorary member of the Institution of Naval Architects, who, in addition to his technical studies, contributed to our knowledge of the theory of waves, aged eighty-four.

Col. H. D. Love, from 1880 until 1907 principal of the Civil Engineering College at Madras, who was also a student of Anglo-Indian history, aged seventy-two.

Mr. R. W. M. Thomson, assistant lecturer in chemistry at King's College, University of London, on November 5, aged twenty-five.

Current Topics and Events.

THE following is a list of those recommended by the president and council for election to the council of the Royal Society at the anniversary meeting on December 1:—*President:* Sir Charles Sherrington; *Treasurer:* Sir David Prain; *Secretaries:* Mr. W. B. Hardy and Mr. J. H. Jeans; *Foreign Secretary:* Sir Richard Glazebrook; *Other Members of Council:* Sir Frederick Andrewes, Prof. J. H. Ashworth, Dr. F. W. Aston, Sir William Bragg, Prof. S. Chapman, Sir Dugald Clerk, Dr. H. H. Dale, Prof. F. G. Donnan, Prof. A. S. Eddington, Prof. E. S. Goodrich, Sir Thomas Holland, Prof. J. B. Leathes, Prof. T. R. Merton, Dr. G. C. Simpson, Prof. J. F. Thorpe, and Prof. F. E. Weiss. The Earl of Crawford and Balcarres and Sir Otto Beit have been elected fellows of the Royal Society under the Statute which permits of elections on the grounds of conspicuous services rendered to science.

H.M. THE KING has approved of the following awards this year by the president and council of the Royal Society:—A Royal Medal to Sir Dugald Clerk for his application of scientific principles to engineering problems, particularly to the development of the internal-combustion engine; and a Royal Medal to Dr. H. H. Dale, for his researches in pharmacology and physiology. The following awards have also been made by the president and council:—The Copley Medal to Sir E. Sharpey-Schafer, for his valuable work in physiology and histology; the Rumford Medal to Mr. C. V. Boys, for his invention of the gas calorimeter; the Davy Medal to Prof. A. G. Perkin, for his researches on the structure of natural colouring matters; and the Darwin Medal to Prof. T. H. Morgan, for his valuable work in zoology, especially his researches on heredity and cytology.

MRS. TYNDALL, widow of Prof. John Tyndall, has made a donation of 500*l.* to the Royal Society to be used at the discretion of the Tyndall Mining Bequest Committee, as a fund to meet out-of-pocket expenses incurred by the Tyndall Research Student in carrying out his investigations. This gift is additional to the sum of 1000*l.* entrusted to the Royal Society in 1910 for the purpose of encouraging and furthering research in all matters pertaining to mining, including such questions as ventilation, temperature, diseases incidental to miners, and so forth. The income of the former gift is utilised to promote research relating to mining, and much valuable work has been done in connexion with the physiological condition of miners and their safety in mines.

THE art of radio communication continues to make marvellous advances. Amateurs have now established communication with New Zealand. To Mr. Boyder, of Mill Hill School (2SZ), must be given the credit of being the first to establish two-way communication with that country. Before 1923, there was a ban on amateur radio in New Zealand, but after that date two kinds of licenses were issued. Those who have a first-class license can use 50 watts for transmission; that is the power taken by an ordinary electric lamp. Those who have second-class licenses are restricted to 5 watts. To obtain a license it is necessary to pass an examination in theory, in the Morse code, and in the regulations. The reception of the signals in Great Britain is erratic. The signal strength is weak at the start, increases gradually, and finally fades away. The period of audibility is between 6.15 A.M. and 7.30 A.M., G.M.T. One interesting fact is that the only New Zealand stations heard are two in the town of Dunedin and one about fifty miles away. The stations in the North Island have not yet been heard in Great Britain.

IN communicating with the Antipodes, the radio waves must travel in both directions round the earth. It is probable that they interfere with one another, producing nodes and loops, and it is possible that the wave-lengths of the two sets of incoming waves may not be exactly the same. It is curious that the two-way working with New Zealand has apparently not been intercepted by any of the numerous workers in America. In the *Radio Review* for Nov. 5, Mr. Orbell gives an interesting account of the phenomena he noticed in a voyage from New Zealand. For example, the United States amateur signals were constantly heard. They reached a maximum strength about halfway across the Pacific, then reached a minimum when rounding Cape Horn. Finally, near Las Palmas in the Atlantic, they regained their maximum strength. The continent of South America seemed to screen them very efficiently. The amateurs of Great Britain and New Zealand are to be congratulated on having made a notable step forward in our knowledge. We venture to predict that short wave-length transmission will play a notable part in long distance transmission in the future.

THE Tokyo correspondent of the *Times* has given in the issue for November 8 an interesting account of the scheme for rebuilding the city. The old narrow alleys, down which no fire-engine could pass, are to be abolished, practically every street is to be widened, and there will be several entirely new main thoroughfares. The total area of all the widened streets will be nearly 13 square miles, but this includes one very large market and numerous parks and open spaces. To obtain the land required for these improvements, every owner is compelled to yield up one-tenth of his present holding without compensation. Open spaces to act as refuges in case of fire are to be provided by building all the primary schools of the city within spacious playgrounds. It was proposed that there should be numerous small parks each with a pool in it to serve as an emergency water-supply, but this plan has been abandoned. Instead of this, some of the canals are to be widened and the water-mains are to be made, so far as possible, earthquake-proof. They are to be constructed on a new elastic principle and supported in conduits without coming in actual contact with the ground.

THE ground floor of the Main Hall of the new Science Museum at South Kensington is at last so far advanced that in a short time it will be thrown open to the public. The six fine old steam engines representing the work of Newcomen, Smeaton, Watt, and others, together with the historic locomotives Puffing Billy, Agenoria, Sans Pareil, and Rocket, were re-erected in the Main Hall some time ago, but now the smaller engines and models are being transferred from the older galleries. When this work is completed, for the first time in the history of the Science Museum the visitor will see the main engineering collections in a proper setting. The increase in floor space is all the more welcome inasmuch as for many years some of the finest collections in the Museum, such as the textile and mining exhibits, have had to be withdrawn from exhibition. As originally planned, the new building—which is but a third of the scheme proposed in 1911—should have been ready for occupation in 1915. The War, however, brought building operations to a standstill, and since 1918 other causes have hindered the progress of the work. With the opening of the New Hall we trust that the Office of Works will do something to improve the so-called temporary entrance as approached by the passage leading from Exhibition Road. Its present state is a standing reproach to those responsible for the upkeep of our national buildings.

ON November 5 the members of the Geological Society Club dined together as usual after the meeting of the Society. The occasion, however, was a special one, being the exact centenary anniversary of the first dinner of the Club in 1824, and a number of distinguished guests were invited to take part in the celebration of the event. Sir William Boyd-Dawkins, who was already a member of the Club fifty years ago when its jubilee was celebrated, proposed the toast of kindred clubs, which was responded to by Sir Charles Sherrington, president of the Royal Society. Sir Arthur Smith Woodward then proposed the guests, to which Sir Richard Gregory and Prof. Schaffer of Vienna responded. The latter remarked that the century of comradeship typified by the existence of the Club dinner appealed more to his imagination than anything else in the geological past. Sir William Bragg proposed the toast of the Club, and Dr. J. W. Evans, in replying, reminded those present of the great changes in geological science since the Club was founded. Then there were no Cambrian, Ordovician, Silurian, or Devonian periods, and the Tertiary had not been subdivided by Lyell, one of the founders of the Club, who survived to take part in its jubilee. There was no glacial period, prehistoric man, or evolution—no rock sections or petrological microscopes. Dr. Evans referred to the importance of the office of treasurer, and proposed the toast of past holders of that post, and more especially of the present treasurer, Mr. G. W. Lamplugh, who, in responding,

remarked his indebtedness to Prof. W. W. Watts, and on the curious coincidence that both at the jubilee and the centenary dinners the president was a John Evans. Letters expressive of good will and regret at their absence, were despatched to Sir Archibald Geikie, Mr. William Whitaker, and Mr. E. T. Newton, honorary members of the Club. They were signed by practically all those who were present at the dinner. An interesting list of the membership of the Club since the beginning was prepared by Mr. Lamplugh and presented to the members and guests.

In our issue of September 13 we dealt with the centenary of the Franklin Institute. We have now received a copy of the booklet published in connexion with the commemoration of that event. It contains a chronicle of some of the most important events in the history of the Institute, an interesting series of illustrations of Philadelphia old and new, some portraits, and also photographs of scientific apparatus, among which we notice Franklin's electrical machine, an air-pump once belonging to Priestley, and Saxton's early magneto-electric machine. The Institute has always encouraged exhibitions of inventions, and to the initiative of its members was due the inauguration of the famous Centennial Exposition of 1876 and the Electrical Exhibition of 1884, both of which had far-reaching results. "For the encouragement of invention and discovery no method is more efficacious," the authors of the booklet appropriately write, "than an exhibit of what has already been done. Two purposes are served. The exhibits stimulate interest and lead to efforts to improve upon what has been accomplished, and show those who are inclined to enter upon invention or discovery in any field what is the 'state of the art,' knowledge that saves many an hour otherwise wasted in going over ground already covered." Franklin's own work as a scientific investigator commenced about 1746, and seven years later he received the Copley Medal of the Royal Society. During his second stay in England he became the friend of Canton, Priestley, Wilson, Maskelyne, and Watson, and he had a share in placing his own lightning conductors on St. Paul's Cathedral. There are many memorials of him in Britain, in France, and in the United States, but none more worthy than the great Institute bearing his name, which was founded thirty-four years after his death.

In the *Empire Review* for November, Dr. R. P. Scott argues that the Bill to release China from further payment of instalments of the Boxer Indemnity, which has been before Parliament since May last, should be amended by defining the undertakings beneficial to both countries, to which the money is to be diverted under the provisions of the Bill, as "Educational or Cultural." Those who know China are agreed that the claims of medicine and surgery for support are valid and obvious, and that the term "cultural" should cover these chiefly, if not entirely. The Chinese national character, both in its strong as well as its weak points, indicates unmistakably the great need of assisting and supplementing the efforts made by the Chinese to reform their educational system. The co-operation of the Chinese themselves is essential, and efforts should be directed towards securing a system of education which, while thoroughly in accord with Western standards, should at the same time be national, unlike at least one of the attempts at reform from outside which has brought disillusion by denationalising the students. Existing institutions, whether Chinese or foreign, should be subsidised, and those which are outside the national system should be kept abreast of it in grade by a system of inspection and advice worked through a conjoint central and local system. It might then be possible to convince China of the value of institutions engaged in developing a Chinese stock which had assimilated Western culture without becoming denationalised. Granted an effective co-operation between British and Chinese workers, it should be possible at the end of twenty-three years, when the payments on account of the indemnity will cease, to judge the experiment on its merits. If it has been successful it should, by that time, be self-supporting.

Sir Alfred Ewing, president of the Royal Society of Edinburgh, in an address on November 3, remarked that in this, the centenary year of Lord Kelvin's birth, it was fitting that the Society should call to remembrance one who was for long its most distinguished fellow, who first became its president at the age of thirty-nine, and was repeatedly re-elected to that office, which he held for twenty-one years in all, and who used the Society as a medium for the publication of many of his most brilliant discoveries. It was to this Society, in 1849, that he gave the account of Carnot's theory which marks the beginning of his study of thermodynamics, and it was also in the Edinburgh Transactions that he published his epoch-making series of papers on the dynamic theory of heat. It was there too that he propounded the doctrine of the dissipation of energy in 1852, and in 1865 briefly refuted the doctrine of uniformity in geology. It was to the Royal Society of Edinburgh that he brought his long series of papers on vortex motion and vortex atoms and his work on the molecular constitution of matter, and his last paper of all, on the problem of a gaseous nebula, was published there posthumously in 1908.

Important and valuable as Kelvin's practical inventions were, continued Sir Alfred Ewing in the address referred to above, and the work in discovery which he continued to do to the end of his life, his very greatest contributions to science were made before he was thirty, when he was engaged in developing the science of energetics. Founding himself on the earlier work of Carnot, he gave to the world the conception of an absolute scale of temperature, and once he succeeded in reconciling the principles of Carnot with the later work of Joule, he pressed forward at an amazing pace, applying the new ideas to one group after another of physical phenomena, and showing that the first and second laws of thermodynamics together formed a master-key to unlock every door. After setting on a sound basis the theory of the pro-

ction of the motive power by the agency of heat, went on to give the principle of the reversible cycle any fruitful applications in other fields. In thermo-ectricity it led him to discover what is now known the Thomson effect. In the theory of electrolysis used it to infer the electromotive force of the lvanic cell from the known energy of the chemical tion. His next step was to discuss the mechanical lues, or as would be now said, the potential energy distributions of electricity and magnetism, and he owed how at every instant of the process of dis-arging a conductor the strength of the current ight be deduced by applying the equation of energy, id how it followed that the discharge would be scillatory, provided the resistance fell short of a rtain limit depending on the self-induction and the pacity. This investigation of transient currents as the first step towards wireless telegraphy, though was left to Clerk Maxwell to recognise, years after-ards, that Thomson's equation omitted one term, amely, the energy of electromagnetic waves, which, as a nsequence of the oscillation, are radiated into space.

MR. T. MARK HOVELL delivered a Chadwick Public ecture on November 10 on "The Rat Menace: its al significance and how it may be minimised." was stated that although rats are costing Great ritain alone 1,000,000*l.* per week, continuous war is ot waged against them. There is a Rats and Mice Destruction) Act, 1919, which authorises fines to the tent of 20*l.*, but it is not put in force. "Rat eeks" do a great amount of good, but there will be o decided diminution in the number of rats until ntinuous trapping is enforced. The presence of a few" rats is usually disregarded; it is not always alised that a pair and their descendants, at a low mputation, will produce in eleven months 1130, and thirteen months 3050 individuals. Farmers usually llow their stacks to be rat-infested, but in six months 132 rats will eat and waste wheat to the equivalent f 2329 quartern loaves, 306 bushels of sharps and 23 bushels of bran. Mr. Mark Hovell also stated hat rats convey trichinosis (measly meat), foot-nd-mouth disease, infectious jaundice, mange, ring-orm, distemper, rat-bite fever, and last, but not ast, plague, which during last March in the Punjab lone caused 25,000 deaths. Plague is conveyed to uman beings by the rat-flea, and, contrary to general elief, the flea of the brown rat transmits plague as eadily as the flea of the black rat. Careful supervision t the ports prevents serious outbreaks of plague in Great Britain. For destroying rats, it appears that irus has no advantage over the recognised poisons, and ts use is strongly deprecated because it disseminates irulent microbes which the medical profession is rying to eradicate. The next Chadwick Public Lecture will be delivered by Prof. J. B. Cohen on Wednesday, November 19, at 8 P.M. in the Gallery of he Royal Institute of British Architects, 9 Conduit Street, on "Smoke: Cause, Nature, Effects and Methods of Prevention." Further particulars of Chadwick Public Lectures may be obtained of the Secretary, Mrs. Aubrey Richardson, at the offices of he Trust, 13 Gt. George Street, Westminster.

SIR OLIVER LODGE has been elected an honorary member of the Institution of Electrical Engineers.

THE Huxley memorial lecture of the Royal Anthropological Institute for the present year will be delivered at 8.30 on Tuesday, November 25, at the Royal Society, by Prof. Réné Verneau, who will take as his subject "La Race de Néanderthal et la race de Grimaldi: leur rôle dans l'humanité."

NOTICE is given that applications for the Government grant for scientific investigations must be sent to reach the Royal Society, Burlington House, London, W.1, not later than January 1, on a form obtainable from the clerk to the Government Grant Committee, c/o the Royal Society.

PROF. E. P. CATHCART, professor of physiological chemistry in the University of Glasgow, has been appointed to the vacancy in the membership of the Medical Research Council caused by the retirement of Prof. D. Noël Paton.

WE learn that Senatore Marconi has returned to London after an absence of about three months, during which time he has been further developing his new beam system. He is now able to state that this system will be effective for efficient telegraph service over any distance by day as well as by night.

THE first of the Christmas Lectures at the Royal Institution, "Concerning the Habits of Insects," to be delivered by Mr. F. Balfour Browne, will be given on Dec. 27, and will be concerned with insect collecting and what it leads to. Succeeding lectures will deal with the habits of bees and wasps (Dec. 30), habits of caterpillars (Jan. 1), habits of the dragon-fly (Jan. 3), habits of the water-beetle (Jan. 6), and the habits of insects and the work of man (Jan. 8).

PROF. WILLARD C. THOMPSON, head of the Poultry Division of the New Jersey State Agricultural Experiment Station, U.S.A., has been appointed Director of the National Poultry Institute (Harper Adams College Section), and has agreed to act in that capacity for two years. Prof. Thompson has done work that has greatly benefited the industry in America, and brings to his new task considerable experience in teaching and research, and a wide knowledge of the problems that confront practical producers.

A TEMPORARY inspector is required by the Ministry of Agriculture and Fisheries mainly for work in connexion with the Young Farmers' Club Movement. Candidates must have a general knowledge of agriculture, and the possession of a University degree and acquaintance with county organisation and educational work is desirable. Application forms (returnable by November 22 at latest) can be obtained from the Secretary to the Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1.

APPLICATIONS are invited for the post of an experimental physicist at the Building Research Station of the Department of Scientific and Industrial Research. Candidates must be honours graduates in physics with research experience, and have a sound general

knowledge of physics, with, preferably, specialised acquaintance with heat and properties of matter. Applications, on a form supplied upon request, should reach the Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1, by, at latest, November 24.

THE Home Secretary has appointed a committee to consider and report whether any, and if so what, modifications of the existing statutory regulations governing the use of artificial humidity in cotton cloth factories are desirable and practicable. The members of the committee are: Mr. J. Jackson (chairman), Mr. L. Bates, Mr. J. Cross, Dr. A. W. Crossley, Mr. G. Green, Prof. Leonard E. Hill, Mr. J. Hindle, Mr. H. Roberts, Mr. F. Scarisbrick, Mr. C. Speak, Mr. John Stuttard, and Mr. D. R. Wilson. The secretary of the committee is Mr. T. P. Threlkeld, of 72 Bridge Street, Manchester, to whom any correspondence should be addressed.

ON October 18, Sir Archibald Garrod delivered the Harveian Oration before the Royal College of Physicians. His subject was "The Debt of Science to Medicine." Like all Sir Archibald's work, his Oration was distinguished by great accuracy and wide learning. He traversed the field from Hippocrates to Sir Edward Sharpey-Schafer and strove to show that science in the pure sense has been greatly enriched by medical men in different ages. Sir Archibald thinks that the marvel is that medical men have contributed so much, not that they have failed to contribute more, considering that clinical medicine is an art as well as a science and that the successful practice of medicine calls for qualities which are often unconnected with science. He pleaded for greater unity between science and practice for those who have the beneficent aims of medicine at heart. The Oration, which will be found in the *British Medical Journal* for October 25, is well worth a careful perusal.

WE have received from the British Museum (Natural History) ten recently issued sets of postcards of butterflies and moths. They are all admirable reproductions by the three-colour process, made from actual specimens, and are among the most perfect examples of that art which have come to our notice. The series of British Butterflies (Nos. 2 to 7), together with their accompanying letterpress, form an excellent guide to those insects which will enable any one readily to identify the various species found in the British Isles. The series No. 2 of British Moths illustrates some of the less common and other species, including the recently detected *Anaitis efformata*. Series Nos. 4 to 6 of Exotic Moths include a number of striking or otherwise remarkable forms. The cards are sold in sets of five (with separate explanatory letterpress) at the low price of 1*s*. per set, and are to be specially commended to all interested in nature study and insect life in particular.

APPLICATIONS for grants from the Chemical Society Research Fund must be received, upon a prescribed form, by the Assistant Secretary of the Society not later than December 1. The Selection Committee of the Harrison Memorial Prize will meet shortly to consider the award of the prize, which is of the value of about 150*l*. The award will be made to the chemist of either sex, natural British born and not more than thirty years of age, who, in the opinion of the committee, has during the previous five years conducted the most meritorious and promising original investigations in any branch of pure or applied chemistry and published the results. Applications must reach the president of the Chemical Society, Burlington House, Piccadilly, W.1, not later than December 1.

Our Astronomical Column.

CALENDAR REFORM.—Mr. G. Marvin, of the U.S. Weather Bureau, read a paper on this subject at the Madrid meeting of the Geodetical and Geophysical Union. He dwelt chiefly on the need of more uniform months for the purpose of meteorological records, and the desirability of keeping the date of the equinox as nearly as possible the same. He recommends the system of 13 months of 4 weeks each, and one day each year (two in leap year) outside the month and week.

Taking account of the shortening of the year due to solar acceleration (Mr. Marvin does not give any details of the amount that he adopts or its source), he notes that the best rule would be to drop 4 leap years in 500 years, instead of 3 in 400 as at present, or 7 in 900 as in the new rule of the Greek Church. He suggests making 1928 a common year to bring the equinox back to March 21, and then to make the centennial years leap years only when divisible by 500: thus 2000, 2500, 3000, etc., would be leap years, the other years ending in 00 common years.

THE BAADE PLANET.—The arc of observation for this planet is now sufficient to deduce approximate elliptical elements, which result as follows:

T	1894 Sept. 27·7609 G.M.T.
ω	130° 0′ 24″
Ω	217 4 35
i	25 27 32
ϕ	30 0 9
Period	3^{y}·8047
log q	0·0858.

The perihelion distance is somewhat greater than that of Eros, and the eccentricity much greater, the aphelion distance being 3·66. The orbit is of the same type as those of Albert and Alinda; the brightness is, however, much greater.

The planet is getting fainter, but is still an easy object for ordinary telescopes. It will be too faint for easy detection at aphelion oppositions, so it is important to observe it over a long arc to secure its recovery in 1928.

EPHEMERIS FOR GREENWICH MIDNIGHT.

Research Items.

MOUND EXPLORATION IN CALIFORNIA.—Observations made in the course of levelling two mounds for city improvements at Richmond, Ca., have afforded several additions of interest to the accumulating evidence relating to the early culture and history of man on the American continent, which is being obtained from archæological investigations in California. The two mounds in question, the Stege mounds, are situated on the Oakland-Richmond beach immediately opposite the outlet of San Francisco Bay in an area about 6 miles long and 3½ miles wide, which includes some of the largest shell mounds of the region, and where the shallow waters provided a favourable ground for fishing in primitive times. The objects found in the course of the demolition of the mounds are described by Mr. Ll. L. Loud in vol. 17, No. 6, of the University of California Publications in American Archæology and Ethnology. They included human remains, some showing signs of incineration, implements of bone and stone, net sinkers, pestles and mortars, the former of several types, hammer stones, and charmstones. The larger of the two mounds afforded abundant evidence that it had been the site of manufacture of objects made of greenstone schist, for which no doubt it had acquired a reputation, and had become a manufacturing and distributing centre according to what appears to have been Indian custom. Of greater interest, however, is the distinction in culture to be drawn between the two mounds, which distinctly points to somewhat different modes of subsistence and may indicate a difference in date.

EARLY DEVELOPMENT OF THE HUMAN EMBRYO.—Prof. T. H. Bryce's "Observations" on this subject have just been published as a separate memoir in the Transactions of the Royal Society of Edinburgh (vol. 53, Part 3, 1924). They should be studied in conjunction with Prof. Teacher's paper on the implantation of the ovum, which was recently noticed in NATURE (Sept. 6, p. 367). Indeed the two memoirs deal largely with the same material, but from different points of view, and so supplement one another. Prof. Bryce, however, besides describing the two Teacher-Bryce ova, includes an account of an entirely new early embryo obtained by Dr. Donald M'Intyre from a uterus removed surgically by sub-total hysterectomy. The memoir contains a number of important observations, some of which are confirmatory of former discoveries and some of which are new. In dealing with the primitive extra-embryonic mesoderm, it is shown that this is primarily an angioblastic tissue. All round the young chorion the formation of vascular channels has begun in it (in the second Teacher-Bryce ovum) before there are any vessels in the yolk-sac and apart from the formation of blood corpuscles. The embryo is afterwards linked up with this system of vascular channels through vessels developed in the allantoic stalk. The author also describes the primary connexions of the yolk-sac and chorion, and points out that the observations support the view that the small size of the yolk-sac in the primates is a secondary condition, its recession being very precocious, but agreeing essentially with what occurs at a later stage in many of the lower mammals. The yolk-sac duct, which is described, is regarded as a vestigial structure reminiscent of a phylogenetic phase when the organ was of larger size. The memoir contains also new and interesting facts relating to the amnion and its duct, the primitive streak and the archenteric canal. It is illustrated by nine plates containing nearly fifty well-executed figures.

OBSERVATIONS ON COLEOPTERA.—*The Entomologist's Monthly Magazine* for October 1924 contains several short articles and notes of interest to coleopterists. Mr. Horace Donisthorpe discusses the European species of the genus Euryusa, the species of which are mymecophilous and live in trees inhabited by ants of the genus Acanthomyops. The exact relations between these beetles and their hosts is still in need of elucidation. Mr. Donisthorpe admits five species and provides a key for their identification. Messrs. J. W. Allen and G. W. Nicholson add a new beetle, *Tachys micros* Fisch., to the British fauna on the strength of taking a considerable number of examples near the coast in Dorsetshire. They also record the occurrence of *Chlaenius schranki* Dufts. in the same situation: this insect was thought to have become extinct since its disappearance from its habitat in the Isle of Wight many years ago. Notes on two beetles recently added to the British list are also included in the same issue of the journal. Mr. B. S. Williams records *Anthicus bifasciatus* from Wicken: it may be added that the insect was first recognised as British in 1914 from Chatteris. Messrs. Allen and Nicholson record *Sitones gemellatus* from Branscombe, S. Devon, where it occurred in some numbers under shoots of *Ononis arvensis*. This insect has only recently been recorded as British, the first examples being found at Sidmouth.

HETEROTHALLISM IN PHYTOPHTHORA.—This problem is carried one step further (see NATURE, Vol. 111, p. 61, 1923) by a paper by C. H. Gadd in the Annals of the Royal Botanic Gardens, Peradeniya, vol. ix. Part I., which gives the results of a comparative study of strains of Phytophthora isolated from cacao, papaw, Hevea, Dendrobium, Odontadenia, and breadfruit in Ceylon. All these strains are regarded by the author as biological varieties of *P. Faberi*. None of them formed oospores so long as grown in pure culture, but they could be divided into two groups, + strains on cacao and papaw and − strains on the other hosts, and oospores were formed when any representatives of these two groups were mingled in cultures. Gadd also confirms the curious earlier result reported by Ashby, that oospores are formed when a pure culture of a strain of *P. Faberi* is mixed with a pure strain of *P. parasitica*. These oospores are of the size characteristic of *P. Faberi* and not of the other species.

THREAD BLIGHTS.—Under this title Mr. T. Petch, botanist and mycologist to the Department of Agriculture, Ceylon, describes (in the Annals of the Royal Botanic Gardens, Peradeniya, vol. ix. Part I.) a number of fungi which have the habit of forming well-defined, narrow strands of mycelium like coarse white threads ramifying over the branches and leaves of plants to a considerable height above the ground. These fungi are frequently seen in the tropics, attention having naturally been attracted to them when they are found on economic plants, as most of them seem to be parasitic, though usually doing little damage except to leaves and young stems. In two or three examples of these thread blights the hyphæ belong to a Corticium. In this case, the hyphæ usually remain thin-walled, and the threads composed of them are more transparent and less conspicuous; but in the majority of the specimens examined by Mr. Petch, in which the hyphæ are derived apparently from gill fungi, apparently species of Marasmius, though adult fructifications have only been described for two species, the bulk of the hyphæ in the threads of the superficial strands are thick-

walled or even solid, so that the threads are white and solid-looking and can withstand desiccation.

BREEDING EXPERIMENTS WITH ANTIRRHINUM.—Prof. Erwin Baur has now published a very full account of his studies of the different races of *Antirrhinum majus*, which he has had under investigation since 1904 ("Untersuchungen über das Wesen, die Entstehung und die Vererbung von Rassenunterschieden bei Antirrhinum majus." Von Erwin Baur. Bibliotheca Genetica, Band 4. Pp. iii + 170 + 8 Tafeln. Leipzig: Gebrüder Borntraeger, 1924. 39*s*. 6*d*.). The large number of forms of this species available in cultivation and the self-fertility of these garden forms have enabled the author to pay especial attention to the origin of mutations in progeny which had remained fixed in type for several generations of selfed parents. Many cases of such mutations are described at length, and Prof. Baur concludes that many of the distinct forms of Antirrhinum occurring in Nature are to be regarded as forms in which a number of different single-factor mutations occurring at different times have been accumulated, environment having then provided the opportunity for the isolation of such as local races. On the other hand, Baur points out that the forms selected in horticulture, on the contrary, usually show a single rather striking mutation that has appealed to the grower, and has been selected and maintained by the efforts of the breeder to keep it genetically pure.

FIXATION OF ATMOSPHERIC NITROGEN BY GREEN PLANTS.—This much-discussed problem comes to the fore again with the publication by Messrs. C. B. Lipman and J. K. Taylor of a full report of their Californian experiments, in the Journal of the Franklin Institute (October 1924, pp. 475-506). It will be recalled that, following in recent years close upon the paper by the late Prof. Benjamin Moore and his colleagues (Proc. Roy. Soc. 91B., 1920), in which nitrogen fixation by Algæ was claimed, but the significance of associated bacteria ignored, Wann published (*Amer. Jour. Botany*, 8, 1921) a series of chemical data which seemed to establish the same fact. Recently, however, the Rothamsted workers Mrs. Roach (Dr. Muriel Bristol) and H. J. Page, working with pure cultures of Algæ, have shown that Wann's claims are invalidated on questions of experimental method, whilst their own careful experiments give negative results. Messrs. Lipman and Taylor have worked with water cultures, especially of wheat and barley, and whilst it will be conceded that their chemical data leave no doubt that plants grown with no other nitrogen supply or with known additional amounts of nitrogen have gained further nitrogen when all other sources except gaseous atmospheric nitrogen seem to be excluded, yet at the same time critics will still argue that the inability to keep the culture solution sterile opens the door to alternative explanations. The writers, however, argue their case very cogently for rejecting the assumption that the gaseous nitrogen is assimilated and handed on to the green plant by bacteria.

PERMIAN INSECTS.—Hitherto few insects have been found in deposits of Permian age, but Sellards and Dunbar (*Amer. Journ. Sci.* vii., 1924, p. 171) have now discovered some thousands of specimens, many in a remarkably perfect state of preservation, in the Lower Permian (Artinskian) of Elmo, Kansas. They include may-flies, cockroaches, dragon flies, etc. This discovery is likely to be of great importance in phylogeny, since during Permian times the later orders of insects seem to have developed out of the more ancient Palæodictyoptera. The collection is being worked out by Dr. R. J. Tillyard. Up to the present he has described a new genus, Dunbaria, which is closely allied to forms found in the Upper Coal Measures of Commentry and is the first example of the Palæodictyoptera to be recorded from the Permian. Protohymen is the type of a new order, the Protohymenoptera, which is ancestral to the Hymenoptera, known first in the Upper Jurassic (*Amer. Journ. Sci.* viii., 1924, p. 111). The insects are found in a marly limestone and are associated with abundant land-plants and with the merostomes Palæolimulus and Eurypterus. The deposits underlying the insect bed contain thick layers of rock salt and other evidence of arid conditions, but the climate became ameliorated during the formation of the insect bed, which seems to have been the marly deposit of a freshwater lake.

LANDSLIPS IN ITALY.—The second number of the new journal *Matériaux pour l'étude des calamités* contains an interesting article by R. Almagia on landslips in Italy. They occur throughout the country, but especially in the sub-Apennine districts, Calabria, etc. The geological formations in which they are most prevalent are the clay strata of the tertiary period. They are most frequent during, or immediately after, periods of exceptionally heavy rainfall, the effect of which may be increased in spring by the melting of the snow, though some landslips may also be due to earthquakes and to deforestation. Some idea of the seriousness of landslips as a calamity may be gathered from the fact that more than three hundred villages in Italy are threatened. The Government has already voted funds for the protection of nearly half of these villages, but for many it is recognised that no adequate protection can be given, and that the only alternative is the removal of the inhabitants. This transfer seems inevitable in as many as seventy-seven villages in Calabria.

NATURE OF ISOSTATIC COMPENSATION.—A paper of interest to students of isostasy has recently been issued by the United States Coast and Geodetic Survey (Isostatic Investigations and Data for Gravity Stations in the United States established since 1915, by William Bowie, Spec. Pub. 99, 1924). Gravity determinations have been made at 94 new stations in addition to the 219 already completed at the beginning of 1916 (Spec. Pub. 40). In the light of all the results now accumulated, Bowie presents his matured views on the nature of isostatic compensation, the processes involved and the geological problems associated with them. He points out that the depth of compensation is not necessarily the same everywhere, but that for the United States the best average value is 96 km. The conclusion recently reached by Nansen in his book "The Strandflat and Isostasy," that movements restoring and maintaining equilibrium can take place within areas only a few hundred kilometres wide, is accepted, and a mechanism suggested. Briefly, the depression of geosynclines in which long-continued sedimentation takes place is ascribed to contraction and consequent increase of density of the block beneath the sinking area. Presumably diagenesis and pressure metamorphism, tending to the production of minerals of small specific volume, is the underlying physical cause. At a later stage, however, rising temperatures gradually reverse the volume changes, and the area begins to be uplifted owing to the expansion of the material of the underlying column. Few geologists are likely to agree with Bowie in his further deduction that mountains have been produced almost wholly by vertical uplift, and not by regional horizontal thrusts. The latter are said by Bowie to be inconceivable from an engineering point of view. Field evidence is nevertheless conclusively in favour of horizontal thrusts;

id for the geologist the two types of movement—ertical uplift and lateral thrusting—are by no vals. Both are required to explain the facts, and oth are probably due to temperature changes in the epths, expansion providing the local uplift, and ne concomitant weakening and fusion of the crust calising the forces of lateral compression set up by he general contraction of the earth.

CLIMATOLOGY OF THE INDIAN OCEAN.—An interesting series of charts of the Indian Ocean showing atmospheric pressure, winds, and currents has been compiled by Dr. P. H. Gallé and published by the Royal Dutch Meteorological Institute (*Mededeelingen en verhandelingen*, 29 *a*). The data have been obtained from the log-books and meteorological registers of the Dutch Navy and Dutch merchant vessels. The author has entered the mean values for January and July in one degree squares. In view of the number of observations, the results in most cases are fairly satisfactory, but Dr. Gallé admits that more accurate mean values could be obtained by further data, and one of his objects in publishing the charts is to invite wider co-operation. Observations are very scanty in some areas, particularly about lat. 30° S., between long. 60° and 90° E., and in winter about lat. 50° S. A comparison of mean values for pressure at land stations around the Indian Ocean, as given by Hann, Lockyer, Braak, and others, with the oceanic pressures, shows a fair agreement, but in places there are striking differences. These the author thinks are due in cases to prevailing local onshore winds and in other cases to a failure to apply accurate corrections for altitude on shore stations. In some of the coast regions two values are given where the divergence was found to be considerable. In regard to winds, these observations show that in the west wind belt of the "forties," the strength and stability of the air currents is not so marked as generally supposed. Further papers in this series are promised.

THE INVERSE STARK EFFECT.—Dr. R. Ladenburg, in the *Zeitschrift für Physik* of September 20, describes the behaviour of the D absorption lines in a strong electrical field. A new form of quartz sodium lamp enables the D lines to be produced with great intensity, and with a breadth of only 0·1 Å, without reversal, so that, using a large Lummer Gehrcke plate, broad interference maxima are obtained. The light from the lamp is passed through an absorption bulb, between two parallel metal surfaces a short distance apart, across which an electric field so high as 160,000 volts per cm. can be produced. The bulb is evacuated in an electric furnace, and pure sodium vapour is introduced. The D_1 and D_2 absorption lines then appear on the continuous background of the interference maxima, and when the light passes perpendicular to the lines of force, the absorption lines are shifted by the field towards the red. The shift amounts to 0·025 Å at 160,000 volts per cm., and is proportional to the square of the field intensity. The phenomena form a typical example of the purely unsymmetrical quadratic effect, which is to be expected according to Bohr's theory with lines unlike those of hydrogen, when the external electric field is small compared with that due to the electrons of the atomic kernel.

SPECTROSCOPY AND ATOMIC STRUCTURE.—The progress made during the past three or four years in the endeavour to discover a structure for the atom of each element which would, on the quantum theory, give a spectrum identical with that found experimentally, has been so rapid that none but specialists have been able to follow it in detail. An article of forty pages in the September and October issues of the Journal of the Franklin Institute by Dr. Paul D. Foote, of the Bureau of Standards, giving an account of the atomic models which have been suggested, will be welcomed by many who have not the opportunity to consult the original memoirs. He deals in turn with the "hydrogenic" atoms, the atoms with several electrons, the assignment of quantum numbers, *i.e.* integers, the necessity for the introduction of "effective" quantum numbers not integral, the orbital and precessional frequencies, and the representation of the orbits of luminous and X-ray frequencies. Figures of the orbits conceived by Bohr for helium, lithium, neon, sodium, argon, copper, krypton, xenon, and radium are reproduced with the warning that they are based on questionable assumptions.

VISCOSITY OF GLASS.—In a recent note on the viscosity of glass (*Comptes rendus*, Paris Academy of Sciences, 1924, p. 517) M. Henry Le Chatelier has shown that the law of the phenomenon can be represented as a function of the temperature by the very simple formula $\log(\log \eta) = -Mt + P$, where η is the viscosity, t the temperature, and M and P constants for a particular glass. Fifteen days later, S. English published in the Journal of the Society of Glass Technology (1924, p. 205) an extensive paper giving numerous viscosity data for different kinds of glass for temperatures ranging from 500° to 1500° C. Applying the formula given above to these data, M. Le Chatelier (*Comptes rendus*, 1924, p. 718) shows that for each glass the results can be expressed by two straight lines meeting at an obtuse angle, the temperature of inflexion varying from 750° C. to 950° C. according to the nature of the glass. To explain these facts, it is assumed that there are two allotropic varieties of each glass possessing different laws for the viscosity variation. This hypothesis was put forward by M. Le Chatelier in his first paper as affording the best explanation of his experiments: it explains equally well the results given by English, which are more numerous and cover a wider range of temperatures.

THALLOUS THALLIC HALIDES.—In the Proceedings of the Cambridge Philosophical Society, vol. xxii, part 3, Mr. A. J. Berry describes some experiments on the sesqui-halides of thallium, $TlX_3,3TlX$, no definite proof of the individuality of which had formerly been given. Solutions of thallous and thallic chlorides containing the two halides in varying proportions were prepared and the composition of the crystals deposited from such solutions determined. It was found that while the composition of the liquid phase could be varied over a wide range, the composition of the solid phase deposited was practically constant. The solution of thallic chloride was prepared by dissolving thallic oxide, obtained from the recrystallised sulphate by oxidation with alkaline potassium ferricyanide, in normal hydrochloric acid. After prolonged heating, the excess of thallic oxide was removed by filtration, and the ratio of thallium to chlorine found to be 1 : 3·1. The compound $TlBr_3,TlBr$ was easily obtained, but $TlBr_3,3TlBr$ was difficult to prepare in a state of purity. $TlBr_3$, $3TlCl$ was prepared. No evidence of the existence of complex ions was found. The substances, mostly red, become very much lighter in colour on cooling in liquid air, and the phenomenon is very strongly marked.

ERRATUM.—In the paragraph referring to "A Biochemical Basis to Disease Resistance" in NATURE of November 1, p. 657, line 11, the sentence "immune forms are comparatively high in total nitrogen and total ash" should read "susceptible forms are comparatively high in total nitrogen and total ash."

Effect of Artificial Light on the Growth of Plants.

THE effect of light on plant life has been the subject of many scientific investigations. So long ago as 1880 Siemens showed that continuous exposure to arc lamps promoted luxuriance of foliage, greater intensity of colouring, and more rapid ripening of fruit. It is common knowledge that plants grown in partial shade are apt to be weakly, and that the flowers, if produced, have in general a fainter shade of colour. Other examples were mentioned by Schübeler in a communication to the British Association in 1881. The extraordinary rapid growth of vegetation in the Arctic regions during the period of uninterrupted daylight has been the subject of comment; likewise the rapid ripening of corn in regions of Norway and Sweden where the summer does not exceed two months, but where, during this period, the sun scarcely sets.

It therefore seems somewhat surprising that greater use has not hitherto been made of the use of artificial light in horticulture. There have, in the past, been intermittent experiments, but results have been somewhat discouraging, and the probable reason is not far to seek. It is only within recent years, when convenient methods of measuring light have become general, that the great disparity between the intensity of full daylight and artificial light has come to be properly understood. The illumination derived from direct sunlight in summer may attain 10,000 foot-candles, and even with a cloudy sky a value of several thousand foot-candles is quite usual. On the other hand, the average illumination in an artificially lighted building is frequently less than three foot-candles; a general illumination of ten foot-candles would be considered exceptionally bright. The marvellous power of adaptation of the eye enables it to utilise these extreme variations in illumination. But it can be readily appreciated that unless an artificial illumination of at least several hundreds of foot-candles can be provided, the effect on the growth of plants would not be marked.

Until a few years ago there were few sources of light that could be conveniently applied to produce such high intensities, and the cost was commercially prohibitive. But the advent of such sources as the electric gas-filled lamp, furnishing 1000 c.p. or more, and capable of being equipped with suitable reflectors to concentrate the available light within a narrow area, has improved the position considerably. For some time experiments have been in progress at various agricultural experimental stations in the United States, and some results of these researches were recently summarised in a series of papers read before the American Illuminating Engineering Society.

The light was provided by electric gas-filled lamps, and values of illumination varying from 300 to 1500 foot-candles were furnished. The exposure to artificial light was supplementary to the natural lighting and had a material effect in hastening the growth of seedlings. Provided that proper attention was paid to the conditions which are ordinarily observed in horticulture—for example, the provision of sufficient space for normal development of each plant, proper soil, maintenance of correct conditions in regard to moisture and temperature, etc.—the more rapid growth was not attended by weakness. On the contrary, the plants were exceptionally robust and, it is stated, less liable to the ravages of fungus and other diseases.

The most striking effect of the increased light, however, was in hastening the time of blooming. On the average, flowering plants came into bloom eight days earlier than when no artificial light was used. Mr. R. B. Harvey, recording tests made at the Minnesota Experiment Station, mentions that the effect of continuous illumination is to cause the accumulation of large quantities of starch in the plants; thus, buckwheat was so full of starch that the grains may be pulverised in the hand. Apparently the desirable illumination varies for different plants. Strawberries, for example, did not bloom at 500 foot-candles, but set fruits at intensities of more than 1500 foot-candles. Prof. H. Findlay, of Columbia University, reports similar experience. The development of bloom in most plants was accelerated by about eight days; marguerites came into bloom eighteen days after the lights were turned on, when similar plants, grown only under sunlight, were scarcely showing bud.

Another question, apart from effect of intensity, is the influence of *colour* of light. It would seem that light from the electric gas-filled lamp may, as regards its effect on vegetation, be regarded as broadly similar to daylight, and probably the same would apply to other illuminants giving continuous spectra and approximately white light. Early experiments on the effect of colour seem to have been somewhat inconclusive, owing to uncertainty regarding the relative intensity. Thus, the effect of inserting a pane of blue glass is naturally to diminish the brightness of the light very considerably, besides restricting the rays to the blue end of the spectrum. Some remarkable results have, however, been recorded by M. Camille Flammarion,[1] who attempted the culture of the sensitive mimosa plant under light of different colours. Plants placed in blue light scarcely gained in growth at all, and also appeared to be in a comatose state, showing none of the sensibility to touch characteristic of the mimosa. Plants grown under red light were, on the other hand, four times as big as those grown under white light, developed well-marked flower balls, and were in an extremely sensitive state. From these and other experiments the conclusion has been drawn that red, orange, and yellow rays, by building up complex organic chains of molecules, stimulate plant life, whereas blue rays have an arresting effect. Ultra-violet rays, when present in excess, undoubtedly may have a prejudicial effect, causing shrivelling of the leaves and ultimately the death of the plant. In judicious proportions, they may, however, prove beneficial, as is believed to be the case in regard to the human body. Instances of their use to destroy greenfly and similar pests have been recorded.

Here, therefore, is a good field for experiment. We have still much to learn regarding the effects of sustained exposure to strong white light, whilst the effect of light of specific wave-lengths has been only very imperfectly studied. It would be very desirable for corroborative investigations, similar to those conducted at research stations in the United States, to be undertaken by leading horticulturists in Great Britain. At present it is not anticipated that artificial light could be economically applied to the production of common foodstuffs on a large scale; but it is believed that its use may prove extremely valuable for the purpose of raising scarce fruits and flowers out of season. It is even possible—though apparently this requires confirmation—that the work might be conducted entirely by artificial light in a well-heated and ventilated cellar in cases where no garden is available, thus bringing this field of investigation within the scope of the town-dweller in congested districts.

[1] Bulletin de la Société Astronomique de France, Aug. 1897.

The Origin of Limestones.

LIMESTONE takes high rank among those common things the proper understanding of which leads one into a wide circle of the sciences. In a British Association lecture at Norwich in 1868 "On a piece of chalk," Huxley declared that any one who acquired a knowledge of the history of a piece of chalk had a far truer conception of the universe, and man's relation to it, than one well-read in human records and ignorant of those of nature. This statement by Huxley concerning a piece of chalk applies with added force to the natural history and uses of limestones as a whole; for it should be emphasised that the use of limestone contributes very largely, and in ways too numerous to mention, to the well-being of civilised communities. It was therefore fitting that, in his recent presidential address to the Washington Academy of Sciences (Journal, 1924, vol. 14, No. 14), Dr. T. W. Vaughan gave a prominent place to a consideration of the origin of limestones.

Limestones occur among the sedimentary rocks, and must have been comparatively scarce, in the bedded form in which we know them, during the early stratigraphical history of the earth. R. A. Daly, indeed, thinks that the ocean-waters of pre-Cambrian times were limeless, and to that condition attributes the absence of fossil remains of calcareous organisms in strata of pre-Cambrian age. It is more probable, however, that any precipitation of calcium carbonate that took place in the earth's primeval ocean-waters left the ocean far from limeless; and it seems more reasonable to attribute the absence of calcareous fossil remains in pre-Cambrian strata either to the evolution time-factor, or to metamorphism of the limestone, rather than to the limeless condition of pre-Cambrian ocean-waters.

Igneous rocks represent the ultimate source from which the lime now found in limestones has been largely derived. The average igneous rock of the earth's crust contains about 5 per cent. of lime. The disintegration of rocks by atmospheric agents is accompanied by the solution of the lime in surface waters, chiefly as bicarbonate and sulphate. The precipitation of calcium carbonate in the sea is effected chiefly by the action of calcareous organisms such as foraminifera (especially globigerina), corals, molluscs, and calcareous algæ.

The importance of globigerina as limestone builders was amply proved by the *Challenger* Expedition, from the results of which it was estimated that globigerina ooze covers an area of about 50 million square miles of the ocean floor, *i.e.* about a quarter of the total surface of the earth. The globigerina ooze passes gradually at greater depth into the red-clay deposits which also cover an area of about 50 million square miles. The globigerina ooze itself contains on an average only about 65 per cent. of calcium carbonate, and incorporates within itself a considerable amount of "colloidal mud" similar in character to the red clay of greater depths. Dr. Vaughan enumerates four sources from any or all of which this "colloidal mud" of globigerina ooze and other oceanic deposits may be derived, namely, (1) outwash from the land; (2) volcanic and other dust precipitated from the atmosphere; (3) the residue from the tests of dead pelagic organisms after these tests have been more or less completely dissolved while falling to the bottom; and (4) the mineral residue from the decomposed soft parts of organisms, some of which may be plankton.

Recent analyses of bottom samples of globigerina ooze collected off the American coasts show that the percentage of calcium carbonate decreases as the depth increases, a fact established previously, in a general way, by the work of the *Challenger* Expedition. The rule is not invariable, however; for, as shown by J. Chumley in a recently published paper (Trans. Roy. Soc. Edin., 1924, vol. 54, pt. 1), the amount of calcium carbonate increases with the depth in some areas. In this connexion, Dr. Vaughan emphasises the fact that limestone of a high degree of purity, containing 95 per cent. or more of calcium carbonate, is usually formed either in shallow or only moderately deep water, and states that the purest limestone is deposited in very shallow water. The statements made in some text-books to the effect that globigerina ooze consists of pure calcium carbonate, and that pure limestone is a deep-sea deposit, are misleading.

The degree of purity of shoal-water limestones depends on the amount of outwash from the land. Where there is no outwash of terrigenous material, a beach deposit may contain more than 95 per cent. of calcium carbonate. The oolites of Key West and the Bahamas, which have been formed in shallow water, contain more than 99 per cent. of calcium carbonate. According to Dr. Vaughan, none of the deep-sea oozes approximate to this degree of purity; but J. Chumley records in one instance 97 per cent. at a depth of 2492 fathoms.

Pure shoal-water limestones appear to be chemical precipitates. They are deposited extensively as particles of "colloidal" size in the vicinity of Florida Keys, where storms give rise to a milky appearance in the water, due to the stirring up of the calcareous precipitate. The calcareous matter of the precipitate consists chiefly of fine particles and aggregates of aragonite. Some coarser foraminifera and molluscan shelly matter are present, but it is characterised chiefly by its minute acicular crystals of aragonite.

Such chemically precipitated calcium carbonate is formed only under peculiar conditions. It is deposited in shallow and relatively stagnant water which is at times heated by the sun above the normal temperature of the freely circulating ocean-water. A sample of water from the west side of Andros Island, Bahamas, showed a salinity more than two parts per thousand higher than that of the normal ocean-water of the region; and there is a considerable amount of organic matter in the mud. An analysis by E. T. Erickson of the calcareous mud at this locality showed the presence of 89·62 per cent. of calcium carbonate, 1·39 of magnesium carbonate, 0·93 of strontium carbonate, and 0·68 of calcium sulphate. The presence of such a considerable amount of strontia (0·63 per cent.) is a feature worthy of special mention.

Efforts have been made by various workers to prove that the calcareous muds of Florida Keys, and other such deposits, have been precipitated by the action of bacteria. The investigations of Drs. G. H. Drew, K. F. Kellerman, and N. R. Smith appear to have established the fact that bacteria are present and very active in the muds of the Great Bahamas Bank and Florida Keys. These bacteria include *Pseudomonas calcis*, which is denitrifying in its action, and vibrios, some of which are strong ammonifiers, the latter being regarded as the more important as agents of precipitation. Dr. Smith inferred from his elaborate investigations that calcium carbonate is formed from calcium sulphate as a result of the growth of bacteria; and that calcium carbonate is formed in natural sea-water by pure cultures if organic matter is added.

It seems reasonable to admit, as Dr. Vaughan does, that the association of ammonifying bacteria with others producing carbon dioxide may result in the formation of ammonium carbonate, which, reacting with calcium sulphate in solution, causes the precipitation of calcium carbonate. Dr. Vaughan points out, however, that the surface layer of ocean-water in tropical and subtropical regions is saturated with calcium carbonate, and that evaporation during the summer months is sufficient to account for the precipitation of calcium carbonate, without the agency of bacteria. Taking the evidence as a whole, it seems legitimate to infer that, although bacterial precipitation is possible, it is quite unimportant as a cause of deposition of calcium carbonate even under the most favourable conditions, and that bacteria cannot compare with foraminifera, corals, molluscs, and nullipores as limestone builders. THOMAS CROOK.

The German Scientific and Medical Association Meeting at Innsbruck.

THE German Scientific and Medical Association —Gesellschaft deutscher Naturforscher und Ärzte—held its eighty-eighth meeting in Innsbruck, Austria, on September 21-27. Many former members are now technically foreigners, domiciled in places once Germany, now called by other names. Hence a curious sort of superimposed internationality on a German-speaking basis, a formal recognition of foreign members, and a need for passports. The Austrian embassies and consulates offered visas free of charge from Berlin, Rome, Prague, Belgrade, Budapest, Buckarest, Bern, Danzig, Copenhagen, Stockholm and Christiania. A very emphatic welcome was given in Innsbruck by the Austrian President, Dr. Hainisch, in the name of the republic, and by Dr. Schneider, Minister of Education, for the Government and by others. There were more than 7000 ticket-holders, including a very few Englishmen, among whom were Prof. G. H. Hardy from Oxford and Prof. G. Barger of Edinburgh. The organisation arrangements seemed excellent. The programme was a pamphlet of 24 quarto pages with a very long list of papers, well cross-referenced to joint sessions, and mutual invitations between the 33 separate sections. The ground covered was similar to that of a British Association plus a British Medical Association meeting. The professors of the University of Innsbruck have fitly inaugurated their new buildings. All who co-operated with them, not forgetting the schoolboys who handed out programmes or wore ribbons and met travellers at the station, are to be congratulated highly on the success of their efforts.

The more popular addresses, corresponding to British Association evening lectures, were taken on the first three mornings of the week. These included Dr. Penck on the aspect of the Alps, Dr. Sommerfeld and others on the Bohr atom model, Dr. Porsch on the pollination of flowers by birds, and Dr. von Frisch on the senses and "language" of bees. Experiments have been made in training bees to feed on coloured paper. They appear to recognise colours, including violet, but scarlet is as black to them. The flower-birds visit bird-flowers with the same range of colours as their own plumage; these include red, yellow, and blue. Dr. Knoll has been watching the humming-bird hawk-moth by a proboscis-track method. He finds that after visiting one flower it leaves tiny traces of sugar water on the next object it touches. Dr. Frisch has followed the bees more exactly in an observation hive where each separate insect was marked and numbered consecutively. He says that bees finding honey report their luck to the hive by a special waddling dance. Their comrades are then stimulated to go out and hunt for flowers with the same scent as the honey brought home.

Among numerous communications to the sections were papers on cellulose, the rôle of alkaloids in the life of plants, sweet taste and chemical constitution, fractional distillation and the non-separation of chlorine isotopes, electrolytic conduction in molten alloys, the fine structure of fibre stuffs, on cyanamides, cyanogen compounds, the electric iron industry in the Tyrol, rapid telegraphy in ocean cables, the Siemens band-microphone, electric conductivity in rock salt and calc spar at high temperatures, quantitative spectrum analysis, the measurement from aeroplanes of radioactive decay products in the air, the formation of nitric oxide in the electric arc, the structure of the earth at different depths deduced from earthquake wave velocities, earth currents in mountains, deformation of individual crystals, microchemical detection of complex iron compounds in living plant tissues, and so on.

A joint meeting of Section I., Mathematics, and Section XV., Mathematical and Scientific Instruction, has considered the Denkschrift (Memorandum) of the Prussian Ministry of Education on the reorganisation of higher school education in Prussia. The Union of German Mathematical Societies and the German Committee for Mathematical and Scientific Instruction have also assisted. The hours allotted to mathematics and science, out of a weekly total of 29, are, in the higher forms of the Gymnasium, 3 and 2; in the Real-Gymnasium, 3 and 4; in the Reform-real-gymnasium, 3 and 3. A minimum of 4 hours weekly for mathematics is demanded. Since the days of Kant, a Weltanschauung without mathematics is impossible; it is a training in conscientiousness and fidelity in detail. Science is not merely necessary for all higher specialised work, but is a necessary element of culture. It is a discussion about hours in the curriculum such as we knew in England a generation ago. In Berlin the history teachers are also perturbed about the Memorandum. It is a matter of rescuing humanity in the largest sense from the humanities in their narrowest meaning. Both aims and methods in education need humanising.

The interest of the meeting was intensified by simultaneous gatherings of other societies in association with particular sections. Such were the German Mathematikervereinigung, the Gesellschaft für angewandte Mathematik und Mechanik, the Gesellschaft für Epidemiologie, the Kolloid-Gesellschaft, the Gesellschaft für Kinderheilkunde.

A long series of excursions, especially for geographers and geologists, had been arranged for the days before and after the meeting. For some of these, early notice had to be given, as numbers were limited and clear instructions necessary—"only for good walkers . . . 7 hours a day . . . bring food . . . climbing boots . . . hotel meals only in evening . . . perhaps only hay-shed."

There were several exhibitions, the exhibits being chiefly by German and Austrian firms, a large collection of new scientific books, scientific and medical apparatus especially for Röntgen rays and synthetic drugs. The schools showed some exceptionally good geometrical drawing, a subject to which great importance is attached. The most attractive exhibit was a film showing the movements of growing plants by the Badische Anilin- und Soda-Fabrik. Photo-

graphs had been taken at 20 minutes' intervals and the film speeded up. There are plotted diagrams in Darwin's "Movement in Plants," but none of us had ever seen such extraordinary gesticulations before.

Funds did not allow of printed abstracts in advance, but very successful arrangements were made by the Press Bureau. Proof sheets containing the more popular parts of the day's work were ready at the end of the afternoon and were widely distributed to the press. More technical papers were represented by typed abstracts.

The Chemist and the Fermentation Industries.

STREATFEILD MEMORIAL LECTURE.

THE annual Streatfeild Memorial Lecture was delivered at the Finsbury Technical College on Nov. 6 by Mr. Julian L. Baker, who selected as his subject "The Chemist and the Fermentation Industries." It was pointed out that the revenue from beer and spirits accounts for about one-sixth of the total expenditure, and the materials from which beer and spirits are made are almost wholly derived from agriculture and for the major part from materials grown in Great Britain. It will, therefore, be apparent that the commercial products of fermentation are derived from biochemical industries of vast extent and of enormous economic value. The very small amount of exact knowledge concerning the changes which starch and proteins undergo during the preparation of malt from barley and the mashing process was referred to, also the difficulties which underlie such investigations. An outline was given of work being conducted under the auspices of the Research Scheme of the Institute of Brewing. Much of this is being done at the Rothamsted, Wye and East Malling Research Stations under the direction of Sir John Russell, Mr. Salmon and others. Prof. Pyman, of the Municipal School of Technology, Manchester, is responsible for the chemical work on the constituents of hops, and the direction of other researches is entrusted to certain other college laboratories.

It is not easy to convince the principals of an industry which is essentially empirical in character that, as knowledge increases, the old order *pari passu* changes. The British instinct is to leave well alone. The endowment of research should be regarded by manufacturers as an insurance. Neither is it reasonable for an industry to expect results from scientific researches which will affect immediately manufacturing operations, or an improvement of output. The success of a brewer is gauged by his product, and, as he is essentially a craftsman, his reluctance to experiment on anything but a small scale can be understood. Such considerations as these militate in no small degree against the generous financing of research.

Reference was made to the manufacture of alcohol and to the "Amylo" process, which cannot be used in England owing to regulations enforced by the Board of Customs and Excise; also to the products, such as glycerol, formed by *S. cerevisiæ* from sugar under certain abnormal environmental conditions, and the production of lactic and butyric acids from sugar by bacterial fermentation. The industries based on the activity of micro-organisms are of profound importance to the community, and the fields of investigation both academic and technical in such industries are limitless.

At the conclusion of his lecture, Mr. Julian Baker referred to the recent decision of the City and Guilds of London Institute to close the College in 1926. The withdrawal of the London County Council grant of 10,000*l*. per annum, to take effect in 1926, was largely responsible for the position. He thought the decline in the number of students, given as a reason for the grant withdrawal, had been unduly exaggerated and was no greater than might be anticipated in view of the action taken in 1920 to close the College and admit no new students in the session 1920–21. Immediate action was necessary on the part of those who valued the real and practical educational facilities offered by the College for the last 46 years, due in the first instance to the curriculum provided in chemistry and engineering by its first teachers, Armstrong, Perry and Ayrton. The practical courses unfettered by any particular examination syllabus should be continued, and it was to be hoped that an influential deputation of manufacturers and educationists would find a way to enable the College to continue its work.

Mr. A. Chaston Chapman considered that the sound practical training, with freedom from examination syllabuses, the great tradition of its past students and teachers, and the service it has rendered should assure the continuance of Finsbury, while Prof. G. T. Morgan pointed out that the goodwill of the College and traditions associated with it could not be continued elsewhere.

Prof. H. E. Armstrong gave an account of his early work at Finsbury with Perry and Ayrton, and emphasised the value which the training had always had in promoting the application of science to industry. The College started under the influence of men like Sir Frederick Bramwell, Lord Halsbury and Sir Owen Roberts, and the courses for training chemists and engineers were unique. Chemical engineering was no new subject at Finsbury. All its chemists received training in the principles of engineering as part of the ordinary course.

Prof. F. G. Donnan, who was unable to be present, sent a letter, in the course of which he said: "The whole cause of higher education in London is suffering at present from the want of autonomy in the principal colleges as regards the examination for the B.Sc. Degree. The old Finsbury system was and is the only one which produces good results, and is in fact the method employed by other civilised countries with the exception of England." Mr. F. H. Carr, who also spoke, agreed that the training offered at Finsbury was of great value to the industries. He considered that we are suffering greatly from what he termed the respectability of degrees.

Mr. A. J. Chapman, president of the Old Students Association, gave an interesting account of the work now being done by the Association to save the College.

University and Educational Intelligence.

CAMBRIDGE.—The Botanic Garden Syndicate reports that with the aid of a further generous gift from Mr. Reginald Cory, it is proposed to provide a house for the Director of the Garden. The Local Lectures Syndicate has presented its fifty-first and last report, it having been superseded by the new Board of Extra-Mural Studies. The report makes reference to the loss suffered by the cause of adult education through the death on Mount Everest of Mr. Leigh-Mallory, Assistant Secretary for Lectures, and also through the death of Prof. H. V. Stanton and Prof. R. G. Moulton.

The Lees-Knowles lectures on military science are being given by Lieut.-Col. F. Nosworthy, on Russia before, during, and after the Great War.

Mr. D. R. Hartree and Mr. E. A. Watkins have been elected to fellowships at St. John's College.

The following have been elected to serve on the

Council of the Senate :—The Master of Corpus Christi and the Master of Sidney Sussex, Sir Ernest Rutherford (Trinity) and Prof. A. E. Brooke (King's), Mr. J. F. Cameron (Gonville and Caius), Mr. F. A. Chase (Trinity Hall), Mr. J. M. Keynes (King's), and Dr. P. H. Winfield (St. John's).

For the fifth year in succession Trinity College announces the offer of a Research Studentship open to graduates of other universities who propose to come to Cambridge in October next as candidates for the degree of Ph.D. The value of the studentship may be so much as 200*l.* a year if the pecuniary circumstances of the successful candidate require so large a sum. Applications must reach the Senior Tutor of the College by July 25, 1925. The College is also offering, as usual, Dominion and Colonial Exhibitions of 40*l.* or (in cases of special need) about 72*l.* to students of Dominion and Colonial universities who wish to come to Cambridge next October as candidates for the degree of B.A., M.Litt., M.Sc., or Ph.D. Candidates must apply through the principal authority of their University, and applications should reach the Senior Tutor of the College (from whom further particulars may be obtained) by July 1, 1925.

GLASGOW.—Prof. H. H. Dixon, whose appointment by the Crown to the Regius chair of botany in the University was recently announced, has intimated to the Secretary for Scotland that, for private reasons, he is unable to accept the appointment. The chair is therefore still vacant, and steps will be taken in due course to make another appointment.

OXFORD.—On November 4, Convocation approved the nomination of Dr. H. Eltringham, New College, as a Curator of the Hope Collections.

A decree has passed Congregation authorising the expenditure of 3000*l.* towards the expense of providing a joint lecture-room, library, and workshop for the Departments of Physiology and Biochemistry.

ST. ANDREWS.—At a meeting of the University Court on October 31, Mr. A. M. Adamson was appointed assistant in the Department of Zoology at St. Andrews, in succession to Mr. D. R. R. Burt.

APPLICATIONS are invited by the Birmingham Education Committee for the headship of the Engineering Department of the Birmingham Municipal Technical School. The necessary form of application, with particulars of the appointment, may be had from the principal of the school, or the Chief Education Officer, Education Office, Margaret Street, Birmingham.

AN article on "Safeguarding the Health of University Students in Europe," by Jean Willems, Secretary of the University of Brussels, appears in the July number of the Review of that University. Brief accounts of what is being done in this matter in other countries are followed by a somewhat fuller description of the work of the German university students' mutual-aid associations and other organisations with which they co-operate. One of the questions they have taken up is that of annual medical examinations. In Dresden, Tubingen, Giessen, Heidelberg, Stuttgart, and Münster-in-Westphalia, schemes for promoting such examinations have been established, generally on a voluntary basis. Students whose health has suffered through being obliged to engage in manual work in order to support themselves while studying, have been sent during the past year to the number of some hundreds for rest cures to rest-homes established for the purpose, where they are treated free of charge by the local physicians. Tuberculous students have been the object of special solicitude. In the autumn of 1923, 160 were lodged in sanatoria for consumptives at the expense of mutual-aid associations and with the collaboration of the German Red Cross Association.

THE Calendar for 1924–25 of University College, London, includes in a thirty-page section devoted to post-graduate courses of lectures a prospectus of work in the new Ramsay Department of Chemical Engineering, the object of which is "to enable young graduates in Chemistry *or* Engineering, who have already obtained a good training in the fundamental sciences of Chemistry, Physics and Mathematics, to direct their studies and investigations towards the application of the principles of Physical Chemistry to the scientific design and operation of the apparatus and processes of chemical industry in general." The second year of the two-year course will be devoted to original research in the laboratories or at industrial works, and will include lectures dealing with the lay-out of plants and factories, factory administration, and industrial economics. The Provost's report mentions that a record of the achievement of a hundred years of work is being prepared for the celebration to take place in 1926. Some strong comments are made by the Dean, of the Faculty of Medical Sciences, and endorsed by the Provost, on the present organisation of medical examinations in the University of London: "We are fettered by a rigid system of examinations which was devised to ensure the attainment of a least common standard in a number of different schools unfortunately this system, with even greater certainty checks any advance beyond such a minimum standard." A movement within the University for bringing these examinations more closely into line with modern teaching is in progress. Appended to the report is an address by the Rt. Hon. Edward Wood on the effect of education on public opinion.

WRITING on "Pioneer Medical Women" in the *Fortnightly Review* for November, Mrs. Fenwick Miller recalls the fact that when the first British Register of Medical Practitioners was established by Act of Parliament in 1858, there was no medical examination open to women in Great Britain, and that the one woman whose name appeared in that register, Elizabeth Blackwell, had obtained her medical education in the United States, at the University of Geneva in the State of New York. After taking her degree she came to England to study at St. Bartholomew's Hospital, where she was admitted to all departments except that of the diseases of women, the professor of which subject "entirely disapproved of a lady studying medicine." She returned to the United States and founded a hospital there and a medical school for women. Miss Elizabeth Garrett (Mrs. Garrett Anderson) qualified for the Licentiate of the Apothecaries Society in 1865, but shortly afterwards the Council of the Society took measures to prevent any other women from following this example. The true pioneer of medical women in Great Britain was Sophia Jex-Blake, born in 1840, and the greater part of the article is devoted to an appreciation of her career—one which fulfilled de Vigny's definition of "une grande vie," namely "une pensée de la jeunesse exécutée par l'âge mûr." She early formed a determination "not to seek a medical career for herself alone, but to open the road to an equal medical standing with men for all other women who wished to follow." The story of her indomitable persistence in pursuing this aim is a stirring one—painful, too, by reason of the discreditable character of much of the opposition she encountered. Her greatest achievement was the establishment of the London School of Medicine for Women, which has this year celebrated its jubilee.

Early Science at the Royal Society.

November 16, 1664. The Secretary produced a small French book, written by father Charles Burgonis against Monsieur Pascal's treatise of the equilibrium of liquors and the weight of the air. The president took it home for his perusal, in order to give an account of it to the society.

1667. Mention being made, that a security might be provided for such inventions or notions, as ingenious persons might have, and desired to secure from usurpation, or from being excluded from having a share in them, if they should be lighted on by others; it was thought good, if any thing of that nature should be brought in, and desired to be lodged with the society, that, if the authors were not of their body, they should be obliged to show it first to the president, and that then it should be sealed up both by the small seal of the society, and by the seal of the proposer; but if they were of the society, then they should not be obliged to shew it first to the president, but only to declare to him the general heads of the matter, and then it should be sealed up, as mentioned before.

1676. Mr. Oldenburg communicated a third letter to himself from Signor Cassini, acquainting the society with some of the astronomical observations made in 1672, by Mons. Rocher, at Cayenne in America, whither he had been sent by the Royal Academy of Sciences at Paris.

1681. The president (Sir Christopher Wren) discoursing concerning the library of the Society, promised to give five pounds to be expended on books of geometry.

November 18, 1663. Mr. Palmer presented the society with a very artificial gun of Caspar Calthof's contrivance, lodging at a time seven bullets and powder in proportion, and discharging them at seven several times. He had the thanks of the society; and it was ordered, that he should be registered as a benefactor. Sir Robert Moray mentioned, that prince Rupert had contrived a gun exceeding all that had hitherto been invented of that kind, discharging several bullets with ease and without danger. Sir Robert Moray was desired to request prince Rupert to send his powder-tryer with a loose and fixed ferrel to the society, to try his experiments of the force of powder therein.

November 19, 1662. Dr. Charlton gave an account of making the powder for embalming birds, and preserving them and their feathers to the life. He was desired to communicate in writing the whole process, according to the relation made by him.

1668. Mr. Oldenburg read a letter from the vice-chancellor of the university of Oxford to Mr. Boyle, importing, that he would endeavour to procure an exchange of the manuscripts now in the possession of the society, for such books as were proper for their purpose. — Mr. Oldenburg produced the curiosities sent from the Bermudas which he had lately retrieved, after having been missing for several weeks, the captain of the ship, to whom they had been recommended, not remembering what was become of them.

November 20, 1673. The lord bishop of Salisbury acquainted the Society, that those eminent citizens of London, who had been formerly deputed by the City and the Mercers' company to invite the Royal Society to return to Gresham College, viz., Sir John Laurence, Sir Richard Ford, Sir Thomas Player, and Mr. Rowland Wynne, had, upon occasion expressed, that they should esteem it as an honour to be elected into the Royal Society: whereupon his lordship now proposed them all four as candidates.

Societies and Academies.

LONDON.

Royal Society, November 6.—T. R. **Merton**: On ultra-violet spectro-photometry. A "neutral wedge" of platinum can be used for measurements of radiations so short as $\lambda = 2100$A. These "wedges" require to be calibrated, both as regards the thickness of the platinum as a function of the distance from the thin end of the wedge, and as regards the density gradient for a given change in the thickness of the platinum as a function of the wave-length. The density gradient is sensibly constant from $\lambda = 4000$A to $\lambda = 2500$A.—W. L. **Bragg** and S. **Chapman**: A theoretical calculation of the rhombohedral angle of crystals of the calcite type. The structure of calcite found by X-ray analysis is built on a series of rhombohedral cells, the edges of which meet at an angle of 101° 55′. Other carbonates and sodium nitrate have a very similar form. The rhombohedral angle of about 102° which is present in all cases is not fixed by the symmetry. The angle has been calculated by a consideration of the equilibrium of the calcite structure. It is assumed that the electrostatic forces correspond to those between a charge of $+2e$ at the centre of the calcium atom, $-2e$ at the centre of the oxygen atom, and $+4e$ at the centre of the carbon atom, and that the force of repulsion is directed from the electrostatic centre of each atom. The crystal is given a deformation which does not alter the distance between neighbouring atoms, so that the forces of repulsion do no virtual work. The electrostatic energy for each configuration is then calculated and a value for the rhombohedral angle found which makes the energy a minimum. This is the condition for equilibrium. The rhombohedral angle so calculated differs by 3° or 4° from the observed value. The alteration in rhombohedral angle, when one metal is substituted for another, is very exactly explained.—O. W. **Richardson** and T. **Tanaka**: (1) The striking and breaking potentials for electron discharges in hydrogen. There are three types of discharge from a thermionic electron-emitting cathode in hydrogen at pressures below 1 mm. The striking and breaking potentials for the discharge which sets in at the lowest voltages have the following properties: (*a*) They fall to a limit as the electron emission of the cathode increases; (*b*) these limiting values have a minimum for a pressure which depends on the electrode distance; (*c*) as the electrode distance is diminished the minimum values of the breaking potential approach a lower limit asymptotically. This limit coincides with the strongest ionisation potential of hydrogen. Spectroscopic evidence is adduced in favour of the view that the type of ionisation which occurs at this point is the splitting of an electron from the hydrogen molecule with the formation of ionised H_2. A considerable number of the lines in the secondary spectrum are selectively affected as regards intensity in the different types of discharge. (2) On a P, Q, and R combination in the many-lined spectrum of hydrogen. Starting from a study of the lines of the secondary hydrogen spectrum which are selectively weakened in a thermionic discharge tube at pressures less than 1 mm., we have been able to arrange 24 lines of this spectrum as members of series, with the designations $P(1) \ldots P(9)$, $Q(1) \ldots Q(5)$ $Q(7)$ $Q(8)$, $R(1) \ldots R(9)$; 15 of the lines satisfy the combination principle

$$P(m+1) + R(m\ 1) = Q(m+1) + Q(m)$$

to within 0·38 wave-number or less. Two others satisfy it to within 0·86. One of these is known to be a blend, and probably the other is also. The

term numbers are not accurately represented by the theoretical formulæ of Kramers and Pauli. The calculated initial and final values of the moments of inertia of the emitters of these lines are $6{\cdot}24 \times 10^{-41}$ and $4{\cdot}80 \times 10^{-41}$ gm. cm.^{2} respectively, and it is probable that the emitter is something heavier than H_2, perhaps H_3.—J. D. **Bernal**: The structure of graphite. The structure of graphite has been examined by the method of the rotating single crystal. The structure is essentially that of Hull, but with all the carbon atoms lying in the cleavage plane, as in the Debye and Scherrer model.—P. L. **Kapitza**: α-ray tracks in a strong magnetic field. Photographs by the Wilson cloud method of α-ray tracks have been taken in magnetic fields of 40,000 to 80,000 gauss. The tracks are curved, and give values for the ratio of the average charge to the velocity of an α-particle at various points along its range. The differences in curvature between individual tracks are probably due to the natural curvature of α-particle tracks.—C. N. **Hinshelwood** and R. E. **Burk**: The homogeneous thermal decomposition of nitrous oxide. The bimolecular nature of the thermal decomposition of nitrous oxide into its elements has been confirmed by a more conclusive method than that previously used by Hunter. The reaction is homogeneous from 838° abs. to 1125° abs. and uncatalysed by platinum or rhodium. The observed rate of reaction can be interpreted in terms of simple thermal activation of the molecules by collision.—C. N. **Hinshelwood**: The kinetics of the interaction of nitrous oxide and hydrogen. The rate of interaction of hydrogen and nitrous oxide has been investigated in the absence of catalysts and in the presence of platinum. The rate of reaction on a platinum wire was followed by measuring the change in the thermal conductivity of the gas mixture as the reaction proceeds. Hydrogèn forms a film on the platinum which retards the reaction. Nitrous oxide reacts with hydrogen when it enters the gaps in this film. The latent heat of evaporation of the film of adsorbed hydrogen, inferred from the effect of temperature on the rate of reaction, is about 25,000 calories per gram molecule.—A. T. **Doodson**: Perturbations of harmonic tidal constants. An examination of the results of analyses of tidal records, as expressed in the so-called "harmonic constants," shows the influences of tidal friction, while one of the perturbations examined has importance in connexion with the dynamical theory of tides in oceans. Some secular changes show that the tides are diminishing in range at some places and increasing in range at other places; changes in the basins of the seas are suggested in explanation.—K. R. **Ramanathan**: The structure of molecules in relation to their optical anisotropy. Pt. I.—R. W. **Wood**: Controlled orbital transfers of electrons in optically excited mercury atoms. Mercury vapour, *in vacuo* at room temperature, is optically excited by illumination by radiation of wave-length 2536. This raises the electrons from the $1S$ orbit to the $2p_2$ orbit. Simultaneous illumination by one or more monochromatic radiations raises the electrons to high levels. From these levels they return to the inner orbits, the vapour radiating wave-lengths corresponding to the orbital transitions involved. By comparing the intensities of the spectrum lines obtained in this way, statistical data regarding the probability of definite transitions under specific conditions may be obtained. Remarkable effects have been observed when helium, nitrogen, and other gases are mixed with the mercury vapour. The addition of nitrogen at 2 mm. pressure causes a thirty-fold increase in the intensity of the green light ($\lambda = 5461$) emitted by the vapour. In this case the phenomenon was found to be associated with the absorption of the line 4046, which is not absorbed at all by optically excited mercury vapour *in vacuo*. The nitrogen apparently brings the electrons on to the $2p_3$ orbit (instead of $2p_2$), for all lines corresponding to transfers from outer orbits to $2p_3$ are powerfully absorbed by the mercury vapour when it is simultaneously illuminated by the 2536 line. Other lines and bands appear with the arc lines of mercury, when other gases are present, notably the great "water-band" in the vicinity of the mercury lines 3125-3131.

Aristotelian Society, November 3.—Prof. A. D. Lindsay, president, in the chair.—Presidential address: What does the mind construct? Many attempts have been made to describe knowing as a process in which the mind is passive, but all have broken down before the fact that at least in error there is something which the mind itself has brought into being. There is, however, a type of mental constructing done in the service of knowledge which alters neither knower nor what is known. The map of a country is a physical reality in the same meaning as the country it represents, and apprehended in the same way, yet it is a mentally constructed thing. This kind of mental construction is possible because there are parts of reality, our bodies, for example, which we control and vary, and other parts over which we have little or no control. These mental constructions which aid us to understand are not copies of the reality they represent; they are diagrams containing in an apprehensible form the elements we want to study. The same is true of mental images, which are the work of constructive imagination. They are of the same kind as models or maps or words. Images involve for their existence a body with a mind and objects external to and acting upon that body. Wherever there is anything of which we can ask whether it is true or false, there is something made by the help of our body, of which we can be aware in the same way as we are aware of the reality to which it refers and to which, if true, it corresponds.

SHEFFIELD.

Society of Glass Technology, October 15.—Col. S. C. Halse, president, in the chair.—Prof. W. E. S. **Turner**: The present position of the glass industry in North America. The cut glass industry has almost entirely died out in America, but coloured glass is growing more important. Pot furnaces are disappearing in favour of tank furnaces. The latter are now being used even for the manufacture of green and blue signal lights, and for selenium ruby glass. Electric light bulbs are practically all made by machines fed from tank furnaces, the glass being the soda-lime-magnesia type. The tubing required for the completion of the lamp is still of the lead glass variety. An epoch-making process for the manufacture of sheet glass is that developed at the glass works of the Ford Motor Company. The glass is melted in tanks, and there is continuous rolling between a pair of rollers, the sheet passing down a lehr about 440 ft. long and afterwards, in sheets, traverses long tables on a continuous belt, where the grinding and polishing are done. The average life of a tank furnace operated by machines is 11 to 13 months. Several factories can show a ratio of fuel consumed to glass produced so low as 0·6.

PARIS.

Academy of Sciences, October 20.—M. Guillaume Bigourdan in the chair.—Henry Le **Chatelier**: The allotropy of glass (p. 731).—Jules **Andrade**: The hypothesis of practical chronometer makers and the method of Résal-Caspari.— **Berloty**: The total

xpse of the moon of August 14, observed at the Kura Observatory (Libau). Details of results ɔlained with the 20 cm. equatorial and with an r cm. telescope.—Edouard **Imbeaux**: The great esian basins of the United States.—Johs **Schmidt**: e immigration of the larvæ of the eel, in the Mediterranean, by the Straits of Gibraltar (*v.* NATURE, January 13, 1923, p. 51, and January 5, 1924, p. 12). —ules **Drach**: The movement of a heavy solid with point fixed. Determination of the group of rionality of the differential equation of the problem. —René **Garnier**: The uniform functions defined by inversion of total algebraical differentials.—G. Viron: Complements to the Picard-Borel theorems. —Serge **Bernstein**: The quasi-analytical functions of Holmann.—Bertrand **Gambier**: A generalisation of the polygons of Poncelet.—J. **Grialou**: Plane vertical vement of liquids possessing viscosity, the state ng permanent.—Benjamin **Jekhowsky**: The ments of the planet Algiers N (1924 QL).—J. Gillaume and Mlle. **Bloch**: Observations made at the Lyons Observatory during the eclipse of the on, August 14, 1924.—W. **Abbott**: The breaking- of the southern polar cap of Mars.—J. **Guillaume**: servations of the sun made at the Lyons Observa- ry during the first quarter of 1924.—R. **Jouaust**: e amplification of the current of photoelectric ls and its application to precision astronomy. It possible with simple arrangements to determine a photographic recorder the time of transit of a ght star if the telescope is of sufficient size. If ry sensitive photographic galvanometers are used, ch as a string galvanometer, smaller telescopes may used for observations on less bright stars.—Nicolas Frrakis and Pierre **Bedos**: A law connecting the isation potential of an element with its boiling int. A formula is given for the relation between e ionisation potential and boiling point and the lues calculated for fifteen elements. The calculated d experimental values are in fair agreement, with e exception of the two elements oxygen and nitrogen. -A. **Dufour**: The wave-length of maximum energy the sound spectrum of an explosion. Analysis of e records of the sound wave of the Courtine explosion ves results in agreement with the theory of M. llard, that the wave-length of maximum energy i the sound spectrum of an explosion varies with the ass of explosive employed.—Mlle. Irène **Curie** and bbuo **Yamada**: The distribution of the length of e α-rays of polonium in oxygen and in nitrogen. om the results described, it follows that the difference form between the Bragg curves in oxygen and in trogen must be attributed to the law of variation ionisation along an α-ray.—Georges **Chaudron** ad Hubert **Forestier**: The allotropy of the oxides iron, chromium, and aluminium.—C. G. **Bedreag**: hysical system of the elements.—A. **Duboin**: The icate compounds of cadmium. The compounds $_2O$. CdO . $4SiO_2$, 2CdO . SiO_2, and 3CdO . SiO_2 ve been isolated.—M. **Risco**: Spectrum analysis the meteorite of June 19, 1924. The meteorite as shown to contain magnesium, aluminium, silicon, otassium, calcium, titanium, vanadium, chromium, anganese, iron, cobalt, nickel, strontium, and ossibly barium.—David **Rotman-Roman**: Some olcanic rocks of the Yémen. Analyses and descrip- ons of comendite and plagitrachyte.—Gustave ivière and Georges **Pichard**: Contribution to the udy of the immediate principles contained in apple aves and the epidermis of apples. The *malol* tracted by Sands from the skin of apples is an id-alcohol, and is re-named by the authors maloloic id.—F. **Picard**: Contribution to the study of the nysiological rôle of the tannins. Their importance the ripening of the shoots of the vine.—Marc **Bridel**: The fermentation hydrolysis of gentiacauline. Preparation of a xylo-glucose, primeverose. Two ferments have been prepared capable of hydrolysing gentiacauline, one prepared from the seeds of *Rhamnus utilis*, the other from *Monotropa Hypopitys*. Both give the same products, gentiacauleine and a new xylo-glucose probably identical with the primeverose of Goris, Mascré, and Vischniac.—H. **Lagatu** and L. **Maume**: A remarkably regular evolution of certain physiological ratios (lime, magnesia, potash) in the leaves of a well-manured vine.—L. **Léger**: An organism of the parasitic Ichthyophone type in the digestive tube of *Lota vulgaris*.—G. **Guittonneau**: The utilisation of mineral nitrogen by the Microsiphoneæ of the soil.—Auguste **Lumière**: Contribution to the study of normal sera.

SATURDAY, NOVEMBER 15.

BRITISH MYCOLOGICAL SOCIETY (in Botany Department, University College), at 11.—Dr. W. Robinson: Conditions controlling Growth and Reproduction in Sporodinia.—A. W. Exell: Hymenial Structure in Three Species of Stereum.—W. J. Dowson: A Die-back of Rambler Roses caused by *Gnomonia Rubi* Rehm.—Miss Clara A. Pratt: The Staling of Fungal Cultures.—J. Ramsbottom: Fragmenta Mycologica.

PHYSIOLOGICAL SOCIETY (at London Hospital Medical School), at 4.—I. Sands: Self Oxidation in the Blood of the Earthworm.—Dr. J. M. H. Campbell, G. O. Mitchell, Dr. M. S. Pembrey, and A. T. W. Powell: The Effect of Muscular Work upon Digestion.—Dr. M. S. Pembrey: The Weight of the Heart in Different Conditions.—Dr. W. Cramer: Self Control and Inhibition in the Adrenal.—Dr. A. V. Anrep and Prof. E. H. Starling: Central and Reflex Regulation of the Circulation.—Prof. H. E. Roaf and W. A. M. Smart: Some Equations based on the Application of the Mass Law to Oxyhæmoglobin Dissociation Curves.—J. R. Marrock: Comparison of Chloride and Iodide Excretion in

Nephritis.—I. de Burgh Daly: A Closed Circuit Heart-Lung Preparation.—Dorothy Patrick: Some Effects produced by the Hooding of Birds.—N. Burgess: The Comparison of Maternal and Fœtal Blood Sugar after the Second Stage of Labour.—Dr. C. S. Myers: A Theory of Sensory Adaptation.

MONDAY, NOVEMBER 17.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.—J. D. Cockcroft, R. T. Coe, J. A. Tyacke, and Prof. Miles Walker: An Electric Harmonic Method of Analysis.

INSTITUTION OF AUTOMOBILE ENGINEERS (Scottish Centre) (at Royal Technical College, Glasgow), at 7.30.—Major E. G. Beaumont: The Maintenance of Commercial Vehicle Fleets.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—H. Bagenal: Planning for Good Acoustics.

SOCIETY OF CHEMICAL INDUSTRY (London Section, Joint Meeting with the Institution of the Rubber Industry) (at Engineers' Club, Coventry Street, W.), at 8.—Dr. A. van Rossem: Latex: its Chemistry and the Development of its Industrial Applications, followed by a discussion opened by B. D. Porritt.

FARADAY SOCIETY (at Chemical Society), at 8.—R. W. E. B. Harman and F. P. Worley: The Hydrolysis of Alkali Cyanides in Aqueous Solution.—Prof. A. P. Laurie: Note on the Expansion of Water while freezing.—S. S. Joshi: The Viscosity of Reversible Emulsions.—D. B. MacLeod: (*a*) The Viscosities of Liquids at their Boiling Points; (*b*) The Kinetic Theory of Evaporation.—J. T. Howarth and F. P. Burt: New Design for Apparatus to measure the Coefficient of Deviation from Boyle's Law, and the Determination of this Coefficient for Acetylene.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Capt. M. W. Hilton-Simpson: The People of the Aures Massif.

TUESDAY, NOVEMBER 18.

ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5.15.—G. Udny Yule: The Growth of Population and the Factors which control it (Inaugural Address).

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Secretary: Report on the Additions to the Society's Menagerie during the month of October 1924.—L. C. Bushby: Exhibition of Specimens from the Caird Insect House.—A. N. Rankin: Exhibition of Photographs taken during the Oxford Spitsbergen Expedition.—M. Burton: A Revision of the Sponge Family Donatidæ.—P. R. Lowe: The Anatomy and Systematic Position of the Madagascan Bird Mesites.—Sir Frederick Mott: Notes on the Gibbon Larynx made during Dissection.—Dr. Ekendra Nath Gosh: The Anatomy of *Parallelipedum* Klein (Mollusca).

INSTITUTION OF CIVIL ENGINEERS, at 6.—W. J. Hadfield: Notes on Modern Practice in Road-making.

ROYAL SANITARY INSTITUTE, at 6.—Miss J. B. N. Paterson and others: Discussion on the Economic Value of the Healthy Infant and the New Zealand Welfare Work to the State.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—J. McGovern: The Influence of Internal Combustion Engines on the Design of Merchant Ships.

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub-Centre) (at the College, Loughborough), at 6.45.—W. Lawson: General and Technical Ideas from the Experience of a Meter Engineer.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at 17 Albert Square, Manchester), at 7.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—A. P. H. Trivelli, E. P. Wightman, and S. E. Sheppard: Note on the Relationship of Photographic Emulsion Fog to Grain Size.—S. E. Sheppard: Grain Size and Distribution in Emulsions.—L. F. Davidson: Conditions governing the Behaviour of the Silver Bromide Grains during Development.—Cambridge Instrument Company, Ltd.: Demonstrations of the Cambridge Photographic Ophthalmoscope and the Cambridge Record Measuring Machine.

INSTITUTION OF AUTOMOBILE ENGINEERS (Wolverhampton Centre) (at Star and Garter Hotel, Wolverhampton), at 7.30.—Major E. G. Beaumont: The Maintenance of Commercial Vehicle Fleets.

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7.30.—Discussion on paper entitled A Proposed Form of Bow Construction, by E. F. Spanner.—G. Austin: A New Electric Drive for Ship and other Auxiliaries.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—Reports on Important Events during the Vacation (World Power Conference, Conference on Illuminating Engineering at Wembley, Meeting of International Illumination Commission, International Conference on Industrial Hygiene, etc.), and Developments in Lamps and Lighting Appliances.

ROYAL ANTHROPOLOGICAL INSTITUTE (at London School of Economics, Houghton Street, W.C.), at 8.15.—Capt. M. W. Hilton-Simpson and J. A. Haessler: Native Life in the Algerian Hills.

WEDNESDAY, NOVEMBER 19.

SOCIETY OF GLASS TECHNOLOGY (at Leeds), at 2.30.

BRITISH CAST IRON RESEARCH ASSOCIATION (at Institution of Mechanical Engineers), at 3.30.—Annual Meeting.

MEDICAL SOCIETY OF LONDON, at 5.—Dr. H. Spencer: The Renaissance of Midwifery (Lloyd Roberts Lecture).

ROYAL METEOROLOGICAL SOCIETY, at 5.—Sir Gilbert Walker: Note on Bjerknes's Contribution of 1921 to the Mechanics of the General Circulation.—W. H. Dines: The Correlation between Pressure and Temperature in the Upper Air, with a suggested Explanation.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.

INSTITUTION OF CIVIL ENGINEERS (Students Meeting), at 6.—P. W. Thomas: Address.

INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.

ROYAL SOCIETY OF ARTS, at 8.—L. B. Atkinson: The Scientific Principles of Artificial Incubation.

INSTITUTE OF CHEMISTRY (London Section), at 8.—Dr. J. J. Fox and V. Stott: Discussion on the Standardisation of Scientific Glassware, with Particular Reference to Units of Volume.

INSTITUTE OF CHEMISTRY AND SOCIETY OF CHEMICAL INDUSTRY (at Caledonian Station Hotel, Edinburgh), at 8.—Prof. G. G. Henderson: The Profession of Chemistry.

C.B.C. SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND PROGRESS (at Essex Hall, Essex Street, W.C.), at 8.—Dr. C. W. Saleeby: Heredity and Degeneracy—some New Discoveries (to be followed by discussion).

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

ROYAL MICROSCOPICAL SOCIETY, at 8.—G. R. de Beer: Comparative Histology and Cytology of the Pituitary Body.—Miss J. Latter: The Development in Lathyrus.—Dr. W. N. F. Woodland: Some Remarkable Caryophylloids from Siluroid Fishes of the Sudan.

THURSDAY, NOVEMBER 20.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IR... (at 11 Chandos Street, W.), at 2.30.—Dr. G. de M. Rudolf: M... Treatment of General Paralysis—some Psychological and Ph... Observations.

ROYAL SOCIETY, at 4.30.—Prof. J. Barcroft, M. L. Anson, A. E. M... and S. Oinuma: The Correlation between the Spectra of v... Hæmoglobins and their Relative Affinities for Oxygen and C... Monoxide.—H. R. Hewer: Certain Abnormalities occurring ... Pituitary of the Frog.—*To be read in title only*:—A. Howard: The ... of Grass on Trees.—Dr. J. W. Pickering and Dr. F. E. Taylor: ... Coagulation, Anti-Coagulants and Hæmolysis.—R. J. Ludford: ... Distribution of the Cytoplasmic Organs in Transplantable T... Cells: with special reference to Dictyokinesis.—E. Ponder: The Ba... like Structure of the Mammalian Erythrocyte.—V. B. Wigglesw... Uric Acid in the Pieridæ: a Quantitative Study.—Dr. G. Li... Johnson: Contributions to the Comparative Anatomy of the Re... and the Amphibian Eye, chiefly based on Ophthalmological Examin...

LINNEAN SOCIETY OF LONDON, at 5.—Prof. F. W. Oliver: Then and ... Photographs taken after Several Years' Time.—C. J. Wills: Eobu... a Fossil Scorpion.—J. R. Norman: Blind Cave Fishes.—Miss ... Blackwell: *Cytisus Adami*.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at ...

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—G. Rogers: Auto... and Semi-Automatic Mercury-Vapour Rectifier Substations.

INSTITUTION OF AUTOMOBILE ENGINEERS (London Graduates Me... (at Watergate House, Adelphi), at 7.30.—D. S. D. Williams, ... Harris, and others: Discussion on the Motor Cycle Show.

CHEMICAL SOCIETY, at 8.—F. Challenger, J. R. A. Jinks, and J. Ha... The Sulphur Compounds of Kimmeridge Shale Oil. Part ... Challenger and T. H. Bott: The Interaction of Thiocyanogen a... Hydrogen Sulphide with Insaturated Compounds. Part II.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at London S... of Hygiene and Tropical Medicine, Endsleigh Gardens) (Labor... Meeting), at 8.15.—Demonstrations by Major Austen, Dr. Broug... Alcock, Dr. H. B. Day, Capt. W. H. Dye, Dr. Drbohlav, Dr. ... Hanschell, Dr. W. E. Haworth, Col. S. P. James, Col. Clayton ... Mr. Ll. Lloyd, Dr. Manson-Bahr, Dr. H. B. Newham, Col. M... Perry, Dr. J. Harvey Pirrie, Dr. H. H. Scott, Surgeon Comm... T. B. Shaw, and A. L. Sheather.

INSTITUTION OF MECHANICAL ENGINEERS (Birmingham Section ... Birmingham).—F. W. Suffield: The Design of an Up-to-date Facto...

INSTITUTION OF MECHANICAL ENGINEERS (Manchester Section) (at ... chester).—W. S. Burge and P. J. Chittenden: Reducing or Pa... Turbines.

FRIDAY, NOVEMBER 21.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (at Liverpool ... versity), at 6.—J. L. F. Vogel: Notes on Alloy Metals used in ... Steels.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Report of the M... Oil-Engine Trials Committee.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), ...—W. H. Ashbee: Photographic Exhibitions and the Public.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—J. G. Hopcraft: Sta... Steel.

INSTITUTE OF METALS (Sheffield Local Section) (at 198 West S... Sheffield), at 7.30.—A. Marks: Non-Ferrous Metals in the Foundr...

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUI... (Middlesbrough Graduate Section) (at Cleveland Institute, Mid... brough), at 7.30.—R. H. Dealtry: Motor-Cycle Carburation.

INSTITUTION OF MECHANICAL ENGINEERS (Liverpool Section) (at I... pool).—W. S. Burge and P. J. Chittenden: Reducing or Pas... Turbines.

PUBLIC LECTURES.

SATURDAY, NOVEMBER 15.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. H. S. Harr... Evolution and Darwinism.

TUESDAY, NOVEMBER 18.

ROYAL BOTANIC SOCIETY OF LONDON, at 3.—Prof. Bickerton: ... Forces of Nature.

KING'S COLLEGE, at 5.30.—Miss Hilda D. Oakeley: The Philosoph... the Absolute in English Thought (1). Bosanquet's Philosoph... Reality and Value.

GRESHAM COLLEGE, at 6.—A. R. Hinks: Astronomy. (Succe... Lectures on November 19, 20, 21.)

WEDNESDAY, NOVEMBER 19.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—Prof. J. B. Co... Smoke (Chadwick Lecture).

THURSDAY, NOVEMBER 20.

BEDFORD COLLEGE FOR WOMEN, at 5.15.—Dr. J. S. Edkins: The Caus... of Sex.

KING'S COLLEGE, at 5.30.—O. V. Salomón: Peru, Old and New (1). ... Ancient Civilisation of Peru.

FRIDAY, NOVEMBER 21.

KING'S COLLEGE, at 5.30.—Prof. E. G. Coker: Scientific Method.

SATURDAY, NOVEMBER 22.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—F. Balfour-Browne: S... Life among Insects. II. Butterflies and Moths.

Science, the Church and Disease.

THERE appears to be little or nothing recondite in the widely advertised dispute concerning missions of "spiritual" healing which has developed within the Church of England. The point at issue was expressed with great clearness and ability by a committee of the Lambeth Conference at the beginning of the year. That committee was at great pains to define its attitude towards the problem which had been submitted to its consideration. It strove boldly and without equivocation to set forth its view of what "spiritual" meant or could mean in relation to the cure of disease. It was to mean primarily and principally a healing of the "spirit"—and the committee explicitly set aside the claims of spiritual healers to any power not evidenced as strongly in ordinary medical practice by persons who professed no religious belief. The committee emptied the ritual of all meaning save as a suggestive technique, but recommended its use.

It is clear, however, from recent events at Bradford and London, that the situation is one of grave concern to many highly placed members of the Church. The Bishop of Manchester says the cures among those who attended the Bradford Mission were "rather few in proportion to the number of cases attending." Dean Inge, in the course of a vigorous protest against "the craze for miracle-mongering, which is part of a widespread recrudescence of superstition among the half-educated," says "only those who have attempted to sift the evidence for a miraculous cure know the shuffling and prevarication with which they are met. In nine cases out of ten the evidence breaks down utterly." Other dignitaries of the Church have uttered warnings which sound merely gloomy and indistinct beside the ironical sentences of the Dean. Their conjoint testimony is sufficient to lead us to the conclusion that a superstitious tendency is being combated by enlightened and informed leaders.

In so far as respect has been shown for the method and results of science, there is no cause for complaint but rather some for satisfaction. If we minimise it, we do so because we are aware that science does not advance either in discovery or in its place in the life of the people merely in proportion to the applause or even the popular assent which it receives, but because each of its revelations constitutes itself at its birth part of man's environment. If any one believes that in certain circumstances of miraculous intervention there are no limits to the suggestibility of the individual human being, positive knowledge will soon come to correct him unless he is right.

Faced with the astounding evidence of credulity which newspaper discussions and public conferences

afford, it is not easy to get near to those aspects of the matter which are important. One of the chief seems to us to be the connexion which undoubtedly exists between the present outbreak of "submerged belief"—to use Dean Inge's phrase—and the so-called "new" psychology. At least one physician of repute has expostulated with even the more sympathetic groups in the Church on the ground of their too ready assumption that Freudian psycho-analysis means modern psychology and neurology. It remains to be seen whether the imposing verbiage now current under the description of Freudian psychology will yield up a single significant fact concerning the mental or physical behaviour of human beings. It spread widely and wildly in Great Britain in company with other "psychical" teachings like Jung's and those of the Nancy school during and after the War because those who very nobly rescued certain of our troops, in the teeth of a reluctant War Office, from the stigma of asylum treatment, had to invoke the authority of a "new" psychology to do so. The recognition of suggestion as a therapeutic agent amounts to little more than the conversion of its unconscious use into a conscious and premeditated use with possibly diminishing success. Technically no resource of the psychotherapist could surpass the "healing" mission in the creation of a favourable atmosphere. If, as the Bishop of Manchester says, the cures are few, we have at least some evidence of the scope for this treatment.

The discussion of "healing" missions brings home the wide interest in psychology albeit ill-informed and misdirected. May it not be, however, that many of the extravagances of the present time might be avoided if sound scientific knowledge were more accessible not to the public alone but also to the medical profession itself? Much has been done of late to bridge the gulf between the medicine of the body and the medicine of the mind; but much remains to be done. Surely it is now time that the science of behaviour should be taught by those who know what is known concerning the organism that behaves. Yet we believe there is not more than one school in London where that could be done soundly and thoroughly.

The interposition of a pseudo-science between biology and its practical application in medicine would, at this stage in the age-long and arduous fight for the liberation of medicine from magic, lead to disaster. It is such an interposition that we are witnessing in the practice of medicine by laymen whether under a religious or a "psychical" guise. The extrusion of such doctrines from scientific medicine and the elaboration of a sound medical psychology can be secured only by giving to psychology its rightful place in the hierarchy of the biological sciences.

Origin and Structure of the Earth.

The Earth: its Origin, History, and Physical Constitution. By Dr. Harold Jeffreys. Pp. x+278. (Cambridge: at the University Press, 1924.) 16*s.* net.

DR. JEFFREY'S book on the earth will be very welcome to the many who are interested in the larger dynamical aspects of our planet, in its present and past states. The book may be divided roughly into three nearly equal parts, dealing respectively with the origin and past history of the earth (considered as a basis for conclusions about its present condition), the theory of isostasy and of the surface features, and finally, various miscellaneous subjects—seismology, the figures of the earth and moon, tidal friction, and the variation of latitude. Despite the generality of the title given to the book, many branches of geophysics are not touched on at all—terrestrial magnetism and electricity, general tidal theory, and meteorology. This was almost inevitable in a book of comparatively small size, particularly since its aim is not to be merely descriptive, but rather to give in some detail the mathematical reasons for the hypotheses adopted.

The first part of the book, on the origin of the earth, overlaps to some extent with Dr. Jeans's recent "Problems of Cosmogony and Stellar Dynamics." The two writers are not in accord on all points, but the degree of agreement is more important than the differences considering that their work has been independent. The earth and other planets are supposed to have been formed by condensation from a gaseous fragment of the primitive sun, torn off from the nearer of the two tidal protuberances raised on the sun during the close passage of a much more massive star. The reasons for rejecting the theory of break-up under the influence of rotation alone are given in a chapter on Laplace's nebular hypothesis.

Jeans has shown that, in order to explain the relatively small mass of the planets compared with that of the sun, the disrupted body must have been highly condensed towards its centre. This seemed to necessitate that the primitive sun must, at the time of the break-up, have been in the giant stage, and on this basis the author sets, as a lower limit to the radius of the sun at that epoch, a distance equal to one-seventh the radius of the present orbit of the earth. He supposes, in fact, that the sun, though far larger than now, was well within the present orbit of Mercury. Jeans, on the other hand, supposed that it extended beyond the present orbit of Neptune; the author gives his reasons for preferring the smaller size. Since the book was written, however, Eddington has cast serious doubt on the view, hitherto tacitly accepted, that the substance of dwarf stars is not in the state of a perfect

gs; if it is, then a dwarf star is as highly condensed wards its centre as a giant star, and the above method fixing a lower limit of size for the sun at the time of eak-up seems to fail.

The further history of the earth is described as llows: it probably became solid near the surface ithin 15,000 years, but remained too hot for the ndensation of water vapour until much later, when ie sun had cooled through the giant stage and become dwarf, probably of type Fo. Geological time starts about this point, when the oceans were formed: and extends over the period of cooling of the sun from ype Fo to its present type Go. Astrophysical reasons e given for supposing that this second period is perhaps n times as long as the pre-geological period, so that ie duration of geological time is nearly equal to ie whole age of the earth. Various methods of stimating this age are given, which roughly agree in dicating a period of a few thousand million years. he most trustworthy method is that based on the anium-lead ratio in the earth's crust.

The thermal history of the earth is worked out on he assumption that the conductivity and other thermal roperties of the rocks affected are independent of epth, that is, of changes of pressure and temperature. Experimental evidence is inconclusive on this point. he result thus arrived at is that below a depth of 00 km. no appreciable cooling has yet occurred, hile at about 300 km. it amounts to between 200° nd 300° C. These figures refer to the part covered by and, the cooling under the oceans being somewhat reater. The physical state of the matter at great epths has therefore probably remained unaltered ince the earth first condensed, that is, it is liquid, nable to transmit distortional waves, and indefinitely eformable by long-maintained shearing stresses. At ntermediate depths, such as 300 km., the rocks will e rigid but probably not "strong," that is, they may e capable both of vibration and flow, like shoemaker's ax. At 100 km. depth the rocks are likely to be ery rigid in the ordinary sense of the term. The earing of these conclusions on the theory of isostasy is considered in detail.

In his discussion of the very controversial question of the method of formation of mountains, the author definitely concludes that the thermal contraction of the earth's crust is a sufficient cause. He estimates the probable reduction of the crust surface by contraction at four thousand million square kilometres, and the reduction necessary to account for the known mountains at half this area. The contraction is supposed to have proceeded gradually until the compressive stresses reached the yield point, mountains then being formed by surface fracture and crumpling. The fractures got sealed up and a period of quiet ensued until further contraction again raised the stresses to the breaking point. Periods of mountain formation thus alternated with quiet periods, and the author estimates, on the basis of his theory, that about six such alternations have occurred hitherto.

Owing to the greater cooling beneath the oceans (which is estimated as being 300° more, at 100 km. depth, than at the same depth under the land, while the sub-oceanic surface of the crust is maintained at a uniform temperature), it is suggested that the crust must have buckled beneath the oceans, the edges being bent downwards. In this way the ocean deeps are explained: in almost all cases they occur near the edges of the great oceans. The rise of extensive areas of sedimentation is also connected with the same phenomenon: the sediments will be deposited round the edges of the land masses, accentuating the tendency of the edges of the sub-oceanic crust to sink, and thereby also increasing the strain at the boundary between the ocean bed and the continental part of the crust. If fracture occurs, the oceanward side of the crust will be more free to bend downward further, but on the landward side of the fault the weight of the sediment may be insufficient to hold down the crust, which may therefore rise and bring the sediments above sea-level.

In the chapter on seismology the theory of earthquake waves is developed directly from the theory of elastic waves in a solid, assuming that the rigidity of the material of the crust increases considerably at a moderate depth (the discussion of the cooling of the crust had already suggested such a change, by indicating that at 10 to 20 km. depth the outer layer of acidic granitic rocks gives place to heavier basic rocks of greater rigidity); and that the underlying strata are sufficiently heterogeneous to cause a good deal of internal reflexion. But the velocities and paths of earthquake waves are still very uncertain, largely because the depth at which earthquakes originate is unknown.

The influence of tidal friction on the rate of rotation and orbital motion of the earth, moon, and other planets and satellites affords one of the most interesting and successful chapters in the theory of planetary dynamics. In the case of the earth, the subject has been put on a really satisfactory footing by Prof. G. I. Taylor's discovery of the paramount importance of tidal friction in shallow seas, supplemented by the author's discussion of the dissipation of energy in the various shallow seas of the globe. The relative unimportance of bodily tidal friction is shown by the persistence of the Eulerian nutation (modified by elastic yielding), as evidenced by the 14-monthly component of the variation of latitude. But the

variability of the amplitude of this component suggests that some damping exists, and also, consequently, some yet unexplained source of regeneration. The variation of latitude also has an annual component which is not adequately accounted for.

The book ranges over so wide a field of knowledge that probably no one critic can be competent to assess the probability of the many hypotheses adopted by the author as a result of his discussions; the process of sifting or confirmation must be left to the efforts of many workers over a long interval. The book might have been improved if Dr. Jeffreys, by means of references to further literature at the end of each chapter, had made it easier for his readers to examine for themselves the sources of observational evidences and the opinions of other writers. Again, some discussion might have been given of the probability of differences of internal motion in the earth, either as set up in the fragments initially torn off from the sun, or induced afterwards through unequal yielding of the earth to tidal retardation, as recently suggested by Eddington; such internal motions would, it is known, be very slowly dissipated by viscosity, and they might have important geophysical effects. But a desire for more information on the subjects discussed in the book must be regarded as a compliment rather than a criticism of the author, whose able and interesting exposition is likely to stimulate further investigation into the problems upon which his own work enables him to write with so much authority and insight.

The Protection of Timber in the Sea.

Marine Structures: their Deterioration and Preservation. Report of the Committee on Marine Piling Investigations of the Division of Engineering and Industrial Research of the National Research Council. By William G. Atwood and A. A. Johnson; with the Collaboration of William F. Clapp, of Robert C. Miller, and of H. W. Walker, H. S. McQuaid and Marjorie S. Allen. Pp. vi + 534 + 14 plates. (Washington, D.C.; National Research Council, 1924.) 10 dollars.

THE deterioration of engineering structures exposed to the action of the sea is at present being investigated by two important research organisations. In Great Britain, a committee of the Institution of Civil Engineers, acting under the Department of Scientific and Industrial Research, was established in 1916 and has issued three interim reports which have already been noticed in NATURE (October 21, 1920, p. 235; December 30, 1922, p. 878; and November 17, 1923, p. 741). In the United States a committee was appointed in 1922 by the National Research Council, following an inquiry by a local committee on a d vastating outbreak of shipworm in timber structur in San Francisco Bay in the years following 1914. Th report of this American Committee, now publishe records a great mass of observations and experiment ably digested and summarised by Col. Atwood, M A. A. Johnson, and their collaborators. While th general scope of the inquiry is the same in both case the American investigators have given less attentio than have their British colleagues to the corrosion c metal structures and have devoted themselves mor particularly to the problem of protecting timber fro the attacks of marine boring animals.

The Committee has realised the need for precis systematic determination of the animals causing dam age, and considerable space is devoted in the repor to the description and illustration of the numerou species of wood-boring Mollusca and Crustacea foun in American waters. Of the molluscan shipworms about two dozen species are named and a number o other forms are recorded which may prove to b distinct species. It is of interest to note that th European *Teredo navalis* is recognised as "one of th most widely distributed as well as one of the mos destructive," occurring both on the Atlantic and or the Pacific coasts of the United States. This is no in agreement with the views of Dr. Bartsch, of th United States National Museum, who has stated tha no shipworm found on the coast of the United State can be identified with any species occurring in othe parts of the world. The zoologists of the Committee appear less inclined to apply the Monroe doctrine to systematic zoology, and they acknowledge a number of immigrants among the Teredinidæ.

The point is not without some practical as well as theoretical interest. It is a characteristic feature in the biology of the shipworms that from time to time they make their appearance in numbers in places where they had not previously been noticed; and it is no less characteristic that, when this happens, "practical men" always begin by attributing their appearance to importation from abroad. Thus Linnæus, when he called the shipworm "Calamitas navium, ex Indiis in Europam propagata," was expressing the common opinion of the eighteenth century, and, quite lately, the destructiveness of *Teredo navalis* in the United States has been attributed to its recent importation from Europe. Perhaps, in some cases, the practical men were right, especially in the old days when wooden ships came home from long voyages with timbers "almost spongy with decay." It is very likely, however, that, more often, excessive multiplication has merely directed attention to a pest that had lurked in odd corners unnoticed because harmless. Sometimes

it s possible to trace the cause of this multiplication in some change of the physical conditions, as the San Francisco outbreaks were found to follow years of deficient rainfall leading to increased salinity of the harbour waters. For many outbreaks, however, no obvious cause can be assigned. Perhaps, as in many other cases, it has been too readily assumed that the increasing or decreasing abundance of a species must be due to man's interference with Nature or to the mutability of weather. It is easy to forget that a fauna is not a fixed unchanging thing but a swaying balance of opposing forces in which now one and now another species may have the higher hand.

The business of the engineer, however, is to find some means of defending his handiwork against possible disaster, and a great part of the report is occupied by an exhaustive discussion of methods that have been used or suggested for warding off the attacks of marine timber-borers. Some kinds of wood are much more resistant than others, but the numerous records here collected and tabulated do not encourage hope that any will be found permanently immune. Methods of protecting timber by means of paints and other surface applications have been investigated, as well as more elaborate and expensive processes of casing the piles with metal or concrete, some of which have given good results. Many processes of impregnating wood with various substances have been tested, and much study has been devoted to creosote impregnation, the most efficient of the methods actually in use. It is pointed out that "after the shipworms have become established and their development has proceeded beyond the larval stage, they seem to work only little less freely in creosoted than in uncreosoted timber," so that the protective value of creosote is due to its action on the larvæ.

In the United States, as in England, the investigators have turned the experiences of warfare to account in their search for poisons that may be used to impregnate wood, and a long and interesting section of the report is contributed by the Chemical Warfare Service. The toxicity of some 45 compounds was tested on larval and adult shipworms and on the crustacean Limnoria. It may be recalled that the British investigators obtained the best results with a substance which they termed phenarsazine, the "D.M." of poison gas warfare. If this be the same as diphenylaminechlorarsine, which the American report identifies with "D.M.," it is remarkable to find that it is here rated very low on the scale of toxicity. It is not included in the list of seven compounds of which it is stated that "between these solutions and all the others there is a decided increase in effectiveness." Experiments are in progress to test the degree of protection given by these and other substances when used for impregnating wood, but these experiments have not yet gone far enough to give conclusive results.

The Committee records two authentic instances of concrete being seriously damaged by rock-boring mollusca. One of these was in the Panama Canal zone, and the damage was mainly due to Lithophaga, a borer which appears to disintegrate the concrete by chemical action. At Los Angeles, on the other hand, the chief agent was a species of Pholadidea, belonging to a family of mechanical borers, which rasp away the rock with their shells. In this case it is not surprising to learn that "a sample of the best mortar in which the borers were found could be readily cut with the thumb-nail."

The report concludes with a bibliography extending to 61 pages closely printed in double columns. It is admirably done and will be of great assistance to future workers. It appears to approach completeness as nearly as any bibliography can; the industry of the compilers has even extended to quotations from the Septuagint and the Vulgate, but the relevance of the passages quoted is not apparent, at least in the Authorised Version. W. T. C.

Laws and Customs in Central Africa.

(1) *The Laws and Customs of the Yoruba People.* By A. K. Ajisafe. Pp. vi+97. (London: G. Routledge and Sons, Ltd.; Lagos: C.M.S. Bookshop, 1924.) 3*s.* 6*d.* net.

(2) *The Bagesu and Other Tribes of the Uganda Protectorate: the Third Part of the Report of the Mackie Ethnological Expedition to Central Africa.* By the Rev. Canon John Roscoe. Pp. xiv+205+32 plates. (Cambridge: At the University Press, 1924.) 20*s.* net.

(3) *White and Black in East Africa: a Record of Travel and Observation in two African Crown Colonies.* By Hermann Norden. Pp. 304+18 plates. (London: H. F. and G. Witherby, 1924.) 15*s.* net.

THE authors of the three books under notice approach their subjects from three entirely different points of view. Mr. Ajisafe is a Yoruba native who puts forward a treatise upon the laws and customs of his own people: Canon Roscoe and Mr. Norden write as foreigners visiting Africa, but, again, their points of view differ. Canon Roscoe is a trained ethnologist; his expedition was organised for the purpose of obtaining information useful to anthropological science. Mr. Norden writes as a tourist, relating the experiences of a pleasure trip in Kenya and Uganda.

(1) The work of Mr. Ajisafe is an extremely useful compendium of the legal and social system of his countrymen; the ordinances of the Yoruba, based upon

age-long tradition, appear to be both just and merciful. Take as an example the following :

" A child's mother being a slave or captive, the child inherits in greater proportion than those children whose mothers are free-born, for the children of the free-born have maternal sides to inherit from while the child of a captive or slave wife has none."

The Yoruba king was, apparently, by no means absolute, and his ministers were responsible to the people for his conduct. In certain cases they could depose him, requesting him to " sleep," that is, to die. The king had " power to declare war, and even send and commission any of his military subjects to wage war against a certain town or tribe." If, however, his subjects were defeated, it seems that it was necessary for him to " sleep " before the unsuccessful expedition returned home. Some of the laws seem strange to us ; for example, the wearing of socks except by " Egungun " was forbidden by native law ; an offender was liable to a heavy fine, imprisonment, or even death.

No less strange was the ordinance " Should a cock in transit crow at the town gate, it is seized and confiscated by the toll collector, the owner in addition to this paying 1*s.* 1*d.* Both the cock and the fee belong solely to the collector."

The book is useful as a record of native customs in a country where European influence is fast increasing. The scientific reader will regret that there is no index, and no adequate vocabulary of native terms.

(2) Canon Roscoe's book is a collection of notes on various tribes, chiefly in the neighbourhood of Mount Elgon, about which, even now, little is known. The first seven chapters deal with the Bagesu, one of the most primitive tribes in Africa. Chapters viii.-xiii. deal with the semi-pastoral Basabei. A chapter is next devoted to the Nilotic Bateso, concerning whom Canon Roscoe has already given us some information in his book " The Northern Bantu." The following four chapters are concerned with the Basoga, with whom the above-mentioned work also deals in part. Further chapters treat of the Bakonjo, the Bambwa, the Bakuntu, and Batuse.

Perhaps the most interesting section of the book is constituted by the chapters on the little-known semi-pastoral Basabei, living upon the north and north-east slopes of Mount Elgon. This tribe observes a system of compensation for murder which is highly unusual. In the case of a fight between two members of the same clan resulting in the death of one, no compensation could be claimed by the parents of the dead man ; but if the deceased were married, his wife's parents were entitled to a cow and a sheep.

" Should the murderer and his victim be of different clans, the clan of the murdered man would demand compensation. The murderer brought to an appointed place ten cows, and two bulls, and members of bo clans met there. One bull and one sheep were kill for the men, and the same for the women, and the cla ate a meal together and were smeared with the co tents of the stomach and some of the blood of t animals. The spear, shield, and knife of the murder man were brought and given to his brother, who al took the skin of one bull and one sheep, while t brother of the murdered man's wife took the rest."

As the tribe practised clan exogamy, the clan of t murdered man obtained next to nothing, and the cl of the victim's wife were the chief gainers. This see inexplicable, unless a husband worked for his wife family, and on his death the latter required a indemnity. Further study of this tribe may affo an explanation.

It would be of interest to have a medical accou of the very drastic form of circumcision perform during the initiation ceremonies of the youths of th tribe. It seems incredible that, immediately after severe an operation as Canon Roscoe describes, t boys should be able to engage in a dance.

It is much to be regretted that folklore relating domestic animals amongst primitive people has be rarely collected. Although in Europe much has be recorded concerning bees and bee-keeping, little h been written by ethnologists on the subject of be culture, and the taboos connected therewith among primitive tribes. Therefore, the information recorded pages 171-2, concerning the taboos observed before t collecting and eating of honey amongst the Bakyiga, very welcome. Canon Roscoe is to be congratulated up the completion of a series of extremely useful report

(3) Mr. Hermann Norden's book is readable a illustrated with good photos. It covers his journ through Kenya and Uganda on the way to the Cong and we hope to hear of his further adventures, aft leaving British territory, in a later volume. T author had perused the records of hunters, missionari and explorers and determined upon obtaining firs hand impressions of this part of Africa. Accompani by his friend Lewis, he entered by way of Zanzibar a Nairobi, and, striking inland, visited the famo troglodyte natives of Mount Elgon for one hou finding this survey sufficient. Many tribes were aft wards visited, and the travellers record their presen at many dances, in most of which the transatlan eyes of Mr. Norden beheld indecency. A fuller accou of the Ja-Luo people, the Nilotic branch of the Ka ondo, is given than of any other tribe, and it is evid that a special study of these folk is needed.

Mr. Norden was appreciative of the work of t British white officials, and seems to have enjoy himself thoroughly. LOUIS C. G. CLARKE.

Our Bookshelf.

Handbuch der biologischen Arbeitsmethoden. Ed. Prof. Dr. Emil Abderhalden. Abt. XI.: *Methoden zur Erforschung der Leistungen des Pflanzenorganismus.* Teil 1, Heft 7 (Schluss), Lieferung 134. *Experimentelle Physiologie der Pflanzenzelle.* Von Ernst Küster. *Serum-Reaktionen zur Feststellung von Verwandtschaftsverhältnissen im Pflanzenreich.* Von Carl Mez. Pp. 961-1123 + xxiv. (Berlin: Urban and Schwarzenberg, 1924.) 6·75 gold marks.

An almost uncanny ingenuity seems to have been shown by the distinguished editor of this series in devising the subjects for monographic treatment, and in attempting the discussion of the experimental physiology of the plant cell, the author has almost inevitably taken refuge in banalities. There is a brief section upon material, which may be summarised as stating that unicellular organisms are more convenient for use and that tissue culture experiments with plants have so far been singularly unsuccessful.

Under the section upon testing material there is a brief discussion of the use of plasmolysis, staining, etc., to determine the vitality of the material under examination. The main part of this monograph may be useful as bringing together data upon a number of different technical methods scattered widely through the literature and including the isolation of microscopic organisms for examination, measurements of growth of single hyphæ, plasmolysis, following the internal movements of certain cell constituents or chloroplasts, the influence of light, centrifugal force, narcotics, etc., upon the cell and its component parts. Micro-dissection methods are briefly referred to, but more space is given to a number of out-of-the-way experimental methods which would certainly be buried in the literature but for this monograph.

The brief monograph upon serum diagnosis is confined strictly to a practical account of the method as employed by Mez, who has injected plant extracts into dogs and afterwards, by the use of precipitin and agglutinin reactions with serum from the animal, investigated extracts of other plants as to their biochemical similarity, relying upon the specific nature of the protein chemistry of these reactions as shown by the experience of animal physiology. This biochemical method is thus employed as a test of relationship as embodied in the current classification of the plants. Work of this nature has filled many pages of German and Japanese botanical journals in recent years, but so far has been left alone by British workers.

Pighude (*Echinodermer*). Af Th. Mortensen. (Danmarks Fauna: Illustrerede Haandbøger over den Danske Dyreverden med Statsunderstøttelse udgivne af Dansk Naturhistorisk Forening.) Pp. 274. (København: G. E. C. Gads Forlag, 1924.) 7·50 Kr.

This little book on the echinoderms of Denmark, by a well-known investigator of the group, is part of a Danish series comparable with the "Faune de France." Considerable progress has been made since the Trustees of the British Museum published the late Jeffrey Bell's "Catalogue of British Echinoderms," but British naturalists will now find their needs almost completely supplied by Dr. R. Koehler's "Echinodermes" and Dr. Mortensen's "Pighude." Between them they cover the English Channel and the greater part of the North Sea. One would have liked some general discussion of the echinoderm fauna as a whole, with its relations to Arctic, Atlantic, and southern faunas, but this book, like Dr. Koehler's, is almost purely descriptive. Two points in which it differs from any previous work of the kind are the description of the larval forms of the species wherever known, and the inclusion of the chief Danish fossil echinoderms. The latter course is practicable for Denmark, because examples are virtually confined to the Chalk. Another useful and unusual feature is the indication of the tonic accent in systematic names, thus: *Soláster éndeca.*

In view of the author's recognised competence it were superfluous to praise the exactitude and clarity of his descriptions, though British readers may get more use from the clear diagrams and photographs with which the book is liberally provided. One does not, perhaps, look in a work of this kind for its author's views on classification; one assumes that a somewhat conservative attitude is adopted for the sake of a wide public. This no doubt explains the retention of Phanerozonia and Cryptozonia as the two orders of starfish, and of Ophiuræ and Euryalæ as the two orders of brittle-stars. Under the sea-urchins we are glad to see the old ordinal name Diadematoidea. In this, as in other features, the book is thoroughly well suited to the working naturalist. F. A. B.

Air Ministry: Meteorological Office. British Meteorological and Magnetic Year Book, 1915. Part 5: *Réseau Mondial,* 1915. *Monthly and Annual Summaries of Pressure, Temperature, and Precipitation at Land Stations, generally Two for each Ten-degree Square of Latitude and Longitude.* M.O. No. 222g (Tables). Pp. xviii+115. (London: H.M. Stationery Office, 1924.) 24*s.* net.

The outstanding feature of this work, gathered from a rough examination, after realising the immense labour in its production, is the valuable step made by the publication of the several annual results towards interpreting aright the causes which influence the weather and its changes in different parts of the globe. The monthly and annual means afford much material for study, especially now that results are available for six years, 1910–1915, and year by year the data are accumulating. For the present volume, observations are utilised for 434 stations. It is to be regretted that so far data from the sea have not been included; over the Atlantic, and somewhat in other oceans, where daily synchronous charts are or can be prepared, observations could be fairly easily obtained. Monthly charts for the several elements would facilitate immensely the study of the material.

The following are typical of some facts to be gathered from the work: the mean pressure results for the year show that the highest mean pressure is 30·22 in. at Tanana in 65° N. and 152° W., the lowest 29·28 in. on the *Endurance* in 73° S. and 44° W. The highest mean temperature for the year is 86° F. at Khartoum in 16° N. and 33° E., the lowest 13° F. at Markovo-sur-Anadyr in 65° N. and 171° E. The greatest annual precipitation is 12,875 mm. (507 in.) at Cherrapunji in 25° N. and 92° E., the bulk of which falls in the four

months May to August. This is more than 20 times greater than the normal for London. A summary is given of the winds at selected stations in the tropics, and notes are inserted on the state of the ice in the Arctic seas and in the North Atlantic Ocean.

Agrikulturchemie. Bearbeitet von Prof. Dr. F. Honcamp; in Gemeinschaft mit Dr. O. Nolte. (Wissenschaftliche Forschungsberichte: Naturwissenschaftliche Reihe, Band 10.) Pp. viii+160. (Dresden und Leipzig: Theodor Steinkopff, 1924.) 0·95 dollar.

THIS small paper-covered volume is a review of the more important investigations in agricultural chemistry published during the years 1914–1920. It is specially intended to help workers who were, perforce, unable to keep in touch with their subject during those years and have not time to go through back numbers of journals. It seems a little late to bring out a summary down to 1920 only; but, in explanation, the editor states that much foreign literature has reached him quite recently.

There are four sections—soils; plant nutrition and manuring; animal nutrition and feeding stuffs; and agricultural chemical methods. Dr. O. Nolte is responsible for the first and last sections. Individual papers are for the most part dealt with very briefly, and the book is written somewhat after the manner of the annual reports to the Chemical Society and the Society of Chemical Industry. Full references are included. The authors show a patriotic bias in their selection of material for mention; but the decision as to what to include in a brief survey of this sort, dealing with a very large amount of literature, must in any case involve a strong personal factor and it is perhaps unreasonable to complain of omissions.

So far as the writer has tested them, the references are accurate and the discussions in the text adequate for the purpose. The book is a painstaking compilation which will prove useful to research workers and teachers of agricultural chemistry.

Manual of Cultivated Plants: a Flora for the Identification of the most Common or Significant Species of Plants grown in the Continental United States and Canada for Food, Ornament, Utility, and General Interest, both in the Open and under Glass. By L. H. Bailey. Pp. 851. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1924.) 31*s.* 6*d.* net.

PROF. L. H. BAILEY has again placed horticulturists in his debt by the publication of his "Manual of Cultivated Plants," in which he has set down the plants commonly grown in N. America, both for use and for their horticultural interest. The book is furnished with keys by which the various species can readily be identified, which are of very great value. The descriptive portion is prefaced by a very useful general account of herbarium methods, terms and names used in botanical science, and a valuable list of the botanists who have given to the plants their specific names. This is followed by a key to the families of the plants referred to in the manual.

The various families are then treated in detail, and concise but adequate descriptions are given of the genera and species. The more important genera or families are illustrated with very useful text figures, which are of considerable value to the plant lover w may not be a professional botanist.

Though the book is written for N. American a Canadian readers, it is not without value to students Great Britain, where most of the plants recorded c be cultivated. It is a model of what such a bo should be to enable plant lovers easily to determi the plants under cultivation in gardens or for econor purposes.

Kant und Einstein: Untersuchungen über das V hältnis der modernen Erkenntnistheorie zur Relativitä theorie. Von Dr. Alfred C. Elsbach. Pp. viii+3 (Berlin und Leipzig: Walter de Gruyter und C 1924.) 8*s.*

THIS book is a study of the important problem of t relation between the space-time theory of Kan "Critique of Pure Reason" and the relativist theo of Einstein. The author, who is of Dutch nationali has already written essays on the subject in his nati language. The present extensive study in German based on the works of the late Hermann Cohen a Paul Natorp, and more especially on the recent wo of Prof. Ernst Cassirer, to whom the book is dedicate Cassirer's "Substance and Function" was reviewed NATURE of August 9, p. 187. The transcendent æsthetic theory of Kant was founded on the classi mechanics of Newton, and intended to give the phi sophical basis of Newton's concepts of absolute spa time, and velocity. There is no more importa problem in contemporary philosophy than to determi whether and how far Kant's doctrine can be adapt to the new physics.

(1) *Immanuel Kant*, 1724–1924: *Gedächtnisrede z Einweihung des Grabmals im Auftrag der Albert Universität und der Stadt Königsberg in Preussen g 21 April 1924 im Dom zu Königsberg gehalten.* V Adolf von Harnack. Pp. 14. (Berlin: Juli Springer, 1924.) 0·25 dollar.

(2) *Immanuel Kant und seine Bedeutung für die Natu forschung der Gegenwart.* Von Prof. Johannes v Kries. Pp. iv+127. (Berlin: Julius Spring 1924.) 0·95 dollar.

THESE two works are issued in connexion with t bicentenary of Kant's birth, recently celebrated in h native city of Königsberg. They were both referr to in our note concerning that event (NATURE, May 1 p. 723). They are now issued separately and convenient form.

Descriptive Labels for Botanic Gardens. By Humphre Gilbert-Carter. Pp. 80. (Cambridge: At the Un versity Press, 1924.) 1*s.* 6*d.* net.

THE booklet of descriptive labels drawn up by th Director of the Cambridge University Botanic Garde is a very useful publication, and it is interesting to se that the practice started at Kew many years ago fo trees has been extended by Mr. Carter to other plants o economic or botanical importance. It may be though that the labels are rather on the "learned" side, bu the inclusion of Arabic and Hindustani words will n doubt be appreciated at Cambridge. Mr. Carter give some very useful suggestions as to methods of prepara tion of these labels in a cheap and lasting manner.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Earth Tides, Ocean Tides, and Local Geology.

I HAVE read with interest Dr. Lambert's letter in ATURE of October 18 with reference to the earth ides observed by means of Hecker's horizontal endulums at Potsdam. These indicated a greater igidity on the earth in a direction a little north of est and south of east. I connected this with the evailing west-north-west and east-south-east strike the folds of the rocks to the south, and probably also those underlying the point of observation.

Dr. Lambert, however, points out that the earth ides are the result of the summation of the effects of ie attraction of the moon and sun on the different oncentric zones of which the earth may be conceived be made up, and contends that as the influence of eological structure does not extend to any great epth, it would not seriously affect the result. It is, n the other hand, possible to show that a higher zone as a greater effect on the tidal movement at the rface than one of the same thickness at a lower level. is easily seen that the direct distortional stress, f, of nar or solar attraction on a zone of the earth's crust proportional to the distance, r, of the zone from the ntre. It is also proportional to the density, ρ, of the ne and inversely proportional to its rigidity, μ. We n therefore write $f = Cr\rho/\mu$ . . . (1), where C is a nstant. But the resulting effect at the surface, F, ill be diminished in the ratio of the area of the zone that of the surface, namely, in the ratio of r^2 to R^2 here R is the radius of the earth. Accordingly $= Cr^3\rho/\mu R^2$. Let C/R^2, which is a constant, be equal to D; then $F = Dr^3\rho/\mu$ . . . (2). But if v is the velocity f the propagation of distortional waves in the zone, e know that $v = \sqrt{(\mu/\rho)}$. Hence $\mu = v^2\rho$. Substituting n (2) we have $F = Dr^3/v^2$ . . . (3). Hence the total ffect of all the zones at the surface $= D\Sigma r^3/v^2$.

Mallet found the velocity in sand to be 0·25 km. er second, and Fouqué and Lévy, that in the Fontainebleau sandstone to be 0·3 km. Dr. Jeffreys and Dr. Vrinch, calculating from the records of the Oppau xplosion, concluded that the velocity of distortional ibrations in typical sedimentary rocks was 0·8 km. nd for the underlying crystalline acid rocks 3·1 km. elow these is a basic magma which extends, it is elieved, down to a depth of nearly 1500 km., and he velocities at different depths have been worked ut by Zoeppritz and Geiger in Germany, and more ecently and accurately by Knott at Edinburgh, from he times of transit of distant earthquake shocks. Knott gives a fairly uniform increase from 3·98 km. er second at the surface to 6·88 at a depth of 1449 km. t is probable, however, that these figures do not pply to sedimentary and acid crystalline rocks near he surface.

Below 1449 km. the velocity varies but little down o 4449 km. This is probably not because the rigidity s constant but because the density increases. The listortional waves cannot be traced to greater depths, ut the effect at the surface of tidal action in this egion must be comparatively unimportant.

We do not know the composition of the rocks at lifferent depths at Potsdam, but to form a general idea of the probable effect at the surface of tidal ction in different zones, we may make a reasonable ssumption of their thickness.

The surface formation at Potsdam consists of unconsolidated sand, and this and similar materials probably extend down to a considerable depth. The velocity near the surface would be about 0·25 km. per second. Let us assume that in the first 2 km. it averages 0·3 km. and that in the next 3 km. of more consolidated sedimentaries 0·8 km. per second, and then for 15 km. in acid crystalline rocks, 3·1 km. per second. Below 20 km. the velocities are taken to be those given by Knott.

The following table shows the velocities at different depths on the above basis and the values of r^3/v^2 indicating the relative tidal effects, at the surface of the earth, of the lunar (or solar) attraction on zones of equal thickness at each depth.

EFFECT ON SURFACE OF TIDAL ACTION IN CONCENTRIC ZONES.

Depth in km.	Radius in km.	Velocity of Distortional Waves, in km. per sec.	r^3/v^2 divided by 10^2.
0* to 2*	6,378 to 6,376	0·3	2,883 to 2,880

6,378	0,000	unknown	0·000

* Depths down to 20 km. are assumed.

If we assume that the influence of the folds extends down to a depth of 80 km., that from a depth of 20 km. to one of 1449 km., dv/dr is constant and equal to $-0{\cdot}00196$, and that from this depth to the centre of the earth v is constant and equal to 6·83, the ratio of the effect at the surface of the earth of the tidal action on the zones influenced by the folding to the effect of such action on the lower zones down to the centre will be about 55 to 78. If, as is usually supposed, the sedimentary and acid rocks as well as the folding extend to greater depths, the former figure will be increased and the latter diminished. In any case, these figures are sufficient to show that tidal action on the upper zones of the earth must exercise a very considerable influence on the movements of the surface, and that differences of direction of structures in the earth's crust cannot be disregarded in explaining the apparent difference of rigidity which has been observed.

As a matter of fact, we have not at present the materials for a definite conclusion. What is urgently needed is a systematic series of observations in a number of localities differently situated with reference to the more important features of the surface of the earth. JOHN W. EVANS.

The Electrodeless Discharge.

IN the electrodeless ring discharge, the type of spectrum produced depends largely upon the voltage drop per mean free path. This is in general only a few volts, under ordinary operating conditions. A comprehensive survey of the entire subject has been given recently by Mierdel (*Phys. Zeit.* 25, pp. 241-55, 1924). As discussed in this article, spark spectra may be excited by increasing the voltage or by reducing the pressure. Both methods have been employed effectively; the former especially by L. and E. Bloch. We have used the latter method with potassium. At high vapour pressure the arc spectrum alone is observed. When the pressure is reduced, the spark lines appear. Observations on the stages in the excitation of known spectra furnish a trustworthy means for estimating the potential gradient in the electrodeless discharge.

The presence of several differently coloured, concentric rings of discharge has been often noted. The voltage gradient is a maximum at the circumference of the bulb and approaches zero at the centre. This effect is beautifully marked with bulbs 25 cm. or more in diameter, especially with the vapour HCl.

We have operated the electrodeless discharge at extremely low pressures. Mercury at 0·002 mm. and iodine cooled to $-50°$ C. are sufficient for a brilliant and uniform luminosity throughout the bulb. In the spectrum of the latter the line at 2063 A is strongly developed.

On disconnecting one terminal of the ring, a "capacity discharge" fills the entire vacuum system and a uniform glow appears in the bulb. The spectrum of this glow from a molecular vapour is usually almost free from atomic lines.

Because of the low pressures under which the electrodeless discharge may be operated with high intensity, it should rival the low voltage arc for the production of sharp, unreversed lines, and by proper adjustment for low field strength, might be desirable as a source in fine structure analysis. It does not appear, however, to be satisfactory for exciting resonance radiation in mercury.

It was thought that this type of discharge should be especially suitable for the production of the hydrogen Balmer lines. At a pressure of a few thousandths of a millimetre, the probability of two dissociated atoms colliding and recombining is small, so that, once the gas is dissociated, further excitation should give the atomic lines. To our surprise only five or six members of the Balmer series were observed. This is probably due to the fact that collisions of electrons having velocities comparable with the ionisation potential, with hydrogen molecules, usually result in excitation or ionisation without dissociation. Franck has recently given some attention to a theoretical discussion of this phenomenon (cf. "Ergebnisse der Exakten Naturwissenschaften," vol. 2, p. 120, 1923, Julius Springer).

If a liquid air trap is sealed directly to the large bulb, and moist hydrogen is streamed through the system, a rapid "clean up" is observed, so that a considerable amount of hydrogen disappears. On removing the liquid air, a momentary, brilliant red flash occurs. We did not determine whether this is due to condensed monatomic hydrogen or simply water vapour.

When a bulb containing mercury vapour at roo temperature is first operated, before the glass wal have warmed appreciably, a beautiful mercury mirr ring is deposited on the glass, concentric with th metal conducting ring. This is due to the tangenti velocity impressed by the circular field upon th mercury ions formed. Under the conditions of o experiment magnetic forces upon the ions may b neglected. Such a large deposit of mercury occu that possibly the method could be modified for th separation of isotopes.

The ring discharge with a large bulb is an effecti means for producing the activated form of nitrog observed by E. P. Lewis. There can be little doul that active nitrogen consists of N_2 molecules in metastable condition. First, evidence in favour this view was the observation by Fowler and Stru that the spectrum of active nitrogen consists of selection of the positive bands, while L. and E. Bloc as well as Foote, Meggers, and Mohler (Cf. "Origin Spectra," p. 190) found these bands to be excite well below the ionisation potential of the molecul Further evidence may be drawn from Strutt observation that no appreciable current flows betwee sounding electrodes (unless these are in actual conta with the luminous vapour), indicating that glowin active nitrogen is not ionised. The production current when the active nitrogen is in contact wit the electrodes, appears to be a confirmation of th Holst-Oosterhuis hypothesis (*Phil. Mag.* 46, p. 111 1923) that excited molecules upon encountering metal surface may liberate electrons. This phen menon might be useful in fixing superior limits f thermionic work functions or for critical potentials.

Saha and Sur (*Phil. Mag.* 48, p. 421, 1924) ha discussed the data of Lewis, Strutt, and Fowler c the excitation of the spectra of gases and met vapours in contact with active nitrogen, and assumin the observed effects to be due to collisions of th "second kind," have estimated the energy of activ nitrogen to be slightly less than 8·8 volts (incorrect computed as 9·4 volts).

We have found that mercury lines requiring 9 volts for their excitation are strongly developed. does not appear that these may be attributed t molecules or atoms having abnormally high tran lational energy. PAUL D. FOOTE.
ARTHUR E. RUARK.

Bureau of Standards, Washington, D.C.

Pyramid and Prophecy.

IN the notice in NATURE of October 25 of the wor entitled "The Great Pyramid: its Divine Message, by the late Dr. H. Aldersmith and myself, the reviewe by a careful selection of remotely secondary feature of the book, convinces himself he has proved the wor to be of the "assertionist class." He represents tha I have obtained the length of the Pyramid base fro the positions of the sockets, which is not the case. H also represents that I have obtained the Pyramid bas side by adding ten inches to the longest existin socket base side, which is also not the case. Si Flinders Petrie's survey has shown that the cor masonry surfaces are hollowed in up the centre, an that the base casing stones still exist in the centre o each base side. With the casing surfaces hollowed i to the same extent as the core masonry surfaces ar hollowed in to receive them, we obtain the Pyrami base circuit of the same dimension as the ancien Egyptian literature shows it to have been, namely

524 units, the unit being of the value 1·0011 British inches.

The reviewer confuses our historical treatment with our treatment of the fictitious chronology of the Egyptians and our treatment of the Jewish chronological forgeries. These are dealt with as separate considerations in our book. The two latter have been moved successively in every stage of evolution, together with the reasons prompting the various changes. They are not, therefore, brought into operation to show the fiction and forgery at a stage in our historical treatment when, as the reviewer alleges, we had "the records are not convenient." The real fact is that the proofs of the said fictions and forgeries are found to be inconvenient for the historical theory our reviewer has adopted.

It is also alleged that our proof of the fixed calendar year in early Egypt is a matter of assertion. An attempt is made to justify this by a misrepresentation. The reviewer selects what he deems to be an exception to a general rule established in the first chapter of the book, and advances this alleged exception as typical of the application of the general rule. Other authorities have already recognised the importance of the data establishing this general rule—as graphically collected on our Plate IX., as proving the fixed year in Egypt. This element is the real disturbing feature of the book to your reviewer, and while it is a remotely secondary feature of the book itself, it is made almost the entire point of criticism.

The whole range of the reviewer's criticism is entirely covered and satisfied by the graphical analyses of our Plates IX., XVI., and XVII. An unbiassed critic, whether an Egyptologist or not, can really satisfy himself, by the examination of these three plates, as to which statements, the reviewer's or our own, "belong to the assertionist class." I am content to let the whole construction of our work rest upon these three plates as a definite basis, if for no other reason than that your reviewer has summarily dismissed all the other really essential features of the work in the last six lines of his criticism.

I would emphasise, in conclusion, that our work throughout has been based on the very trustworthy archæological and metrological *facts* of Sir Flinders Petrie, but that our co-ordination of these and other related *facts* has compelled us to reject his elaborate Egyptological *theories*. Unfortunately, your reviewer evidently considers a thesis to be "devoted to confusing the public mind" if it fails to accord with the *theories* of the Petrie school of Egyptology.

D. DAVIDSON.

47 Park Square, Leeds,
November 5.

THE review referred to the physical statements, which were suitable because they could be dealt with on ground familiar to the readers of NATURE. They were not "remotely secondary," but are put in the forefront of the volume, in the first 64 pages, and are referred to as a basis for other assertions. The assumed curvature of the casing of the pyramid is contradicted by the mark of the edge of the casing, which is now exposed at the north-east corner; it was straight within an inch. The length of the sides is asserted to have been 9141 inches, and this involves disregarding the sockets, and adding 10 inches to the longest socket side. The intricate assertions about chronology could not be discussed in a year of NATURE; but it is a safe method in all treatment of complex matters to look at the product; if that is physically impossible it is of no effect to argue about the detail. Now the proposed contemporaneousness of the Dynasties XII. and XIII., and the blank left between 1477 and 1216 B.C., are impossibilities in any view held by any scholar familiar with the monuments. Such a sample, of fundamental importance, relieves us from discussing how such results are reached. All that a discussion could prove would be the untrustworthiness of its material or method. There are well-known equations proving that $a=2a$, but they do not convince.

THE REVIEWER.

Spectrum Observations on the Copper Arc.

DURING some work in this laboratory with the copper arc, certain pole effects were observed. The arc was formed by two rods of pure copper, 4 mm. in diameter. The length of the arc was 6 mm. and the current strength 3 amp. on a 220-volt circuit. An image of the arc was projected on to the slit of a Hilger quartz spectrograph (size E.1), the arc being in line with the slit.

Above λ2800, practically no effects were observed, but below this wave-length a number of lines showed a change of intensity between the centre of the arc and the two poles. Lines at the positive pole were more intense than at the negative pole, while a few lines were seen in the positive pole only. Table I. was drawn up according to the notification of Merrill (*Astro. Jour.*, v. 56, p. 475).

TABLE I.

λ.	Group.	λ.	Group.	λ.	Group.
2824·378	1	2276·244	3	2192·236	3
2544·85	5	2263·09	1	2189·599	4
2489·659	4	2246·984	3	2181·68	1
2442·625	1	2242·599	4	2179·37	3
2406·661	1	2230·071	1	2148·93	4
2403·327	5	2228·845	4	2135·92	4
2400·102	3	2227·74	1	2125·978	5
2369·877	3	2218·079	3	2122·916	5
2303·109	2	2210·240	4	2112·023	4
2294·353	4	2199·65	2		

Group (1) slight observable increase, (2) small increase, (3) considerable increase (about twice), (4) great increase, (5) very great increase.

The following lines showed a greater reversal towards the negative pole: 2293·832, 2263·09, 2230·071, 2227·74, 2225·665, 2215·65, 2214·56, 2199·65, 2181·68, 2178·91.

Among the lines found by Shenstone (NATURE, v. 114, p. 501 (No. 2866)) in an 8-volt copper arc, 2293·832 was the only line showing an appreciable change of intensity. The wave-lengths given above are Hasbath's as given in "Handbuch der Spectroscopie" (Kayser and Konen), vol. 7. Basing a Hartmann formula on the lines 2148·93, 2112·023, and 2054·88 (Hasbach's Values), the wave-lengths of the following four lines were interpolated: 2138·49 (Hasbach, 2138·44; Huppers ("Handbuch der Spectroscopie," Kayser and Konen, vol. 7), 2138·54); 2105·03; 2104·70 (Hasbach gives one line at 2104·717); 2079·53 (Pina, *loc. cit.*, 2079·47). The line given by Hasbach at 2085·22 was not found. The dispersion of the instrument in this region is 0·7 mm. per angstrom.

The Molecular Weight of Glycogen.

RECENTLY Mr. W. K. Slater has prepared glycogen in a high degree of purity, and has commented on the difficulty of obtaining the polysaccharide in an anhydrous form (*J. Physiol.* 58, 163, 1923; *Biochem. J.*, 18, 621, 1924). This observation may be of significance in connexion with the molecular weight of the higher polysaccharides for a reason which I have not hitherto seen discussed, although it is probably familiar to some of your readers.

When the general formula for the complete hydrolysis of a lower polysaccharide, such as *raffinose* or *stachyose*, is considered, it will be seen that the saccharide on being converted into n molecules of hexose requires only $(n-1)$ molecules of water:

$$\underset{\text{Raffinose.}}{C_{18}H_{32}O_{16}} + 2H_2O = 3C_6H_{12}O_6,$$

$$\underset{\text{Stachyose.}}{C_{24}H_{42}O_{21}} + 3H_2O = 4C_6H_{12}O_6.$$

Applying this equation to the hydrolysis of a higher polysaccharide, such as *glycogen*, it would appear either that (1) the higher polysaccharide exists in some stage of the hydrolysis as a cyclic compound requiring the addition of two molecules of water in order to produce two derivative molecules; or that (2) the simple equation for the hydrolysis of a polysaccharide is not quantitatively correct, and instead of being:

$$(C_6H_{10}O_5)_n + nH_2O = nC_6H_{12}O_6$$

it should be:

$$(C_6H_{10}O_5)_n + (n-1)H_2O \rightarrow nC_6H_{12}O_6.$$

Now, if n molecules of hexose be formed from the hydrolysis of one molecule of a polysaccharide by the addition of $(n-1)$ molecules of water, the formula for a polysaccharide must be:

$$(C_6H_{10+2/n}O_{5+1/n})_n$$

and the equation becomes:

$$(C_6H_{10+2/n}O_{5+1/n})_n + (n-1)H_2O = nC_6H_{12}O_6.$$

Consequently, from a percentage analysis of a pure polysaccharide the value of n may be obtained by calculating the difference between the observed value for the hydrogen $(H_{10+2/n})_n$ and the theoretical value $(H_{10})_n$ found from the $(C_6H_{10}O_5)_n$ formula.

The Uniform Development of Photographic Plates.

IN the issue of NATURE for April 5 we directed attention to the limit of accuracy which is imposed on all methods of photographic photometry, by lack of uniformity in the manufacture, or development of photographic plates. In most cases these errors are much larger than any other errors, and, as the photographic method of photometry is so much used at present, it is very desirable that these errors should be removed.

From various considerations it appears that by no ordinary method of development can fresh developer be supplied to the surface of the plate as fast as the plate can use it, (or, alternatively, the products of development cannot be removed so quickly that they do not remain in appreciable concentration). The result is that any local increase in eddy motion in the developer gives rise to a darker image. If, however, the eddy motion close to the plate could be made so great that fresh developer could be supplied more quickly than it could be used, any small change in turbulence should cause no change in the development.

With this in view, we have tried a developing tank in which the plates are held against the vertical wall and a piston nearly fitting the tank is moved up and down past the plates. Thus the developer is caused to flow at a high velocity through the narrow opening between the piston and the plates. The violent eddies produced effect very thorough mixing.

Developing ordinary commercial plates in this way we have obtained much greater uniformity of density than we can get by any other method, and the results are better than any others published which are known to us, including those obtained with specially prepared plates on flat glass.

Aquarium Technique.

MAY I claim the hospitality of your columns to publish a method of getting rid of blue-green algae from aquarium cultures for biological teaching? In procuring inoculation material for starting Amœba, Actinosphærium, Rotifer, etc., cultures (see NATURE vol. 102, p. 166; vol. 105, p. 232), blue-green algal spores are frequently included in the "catch." These latter develop quickly, the resulting filaments becoming troublesome inhabitants of the cultures, binding down the other contents and interfering generally with the well-being of the micro-organisms.

I have been experimenting for some time with various chemicals, and have found that ferrous sulphate is an excellent poison for the blue-green algæ, while at the same time it appears to be a "tonic" for the amœba, actinosphærium, and rotifer. In a bad case of infection it was necessary to add 1 gram to a bulk of 2 litres of liquid (June 5). At the time of writing this note, November 1, the rotifer culture so treated is in a flourishing condition.

While awaiting the publication of a paper on *Amœba proteus* (where the subject of hydrogen ion concentration and amœba cultures is dealt with more fully) it may be of interest to the many people who have applied to me for assistance in starting cultures to know that ferrous sulphate has also been used with success for restoring the optimum P_H of the water of an amœba culture that had departed too far from that value for the well-being of the amœbæ.

British Actiniaria.

I AM preparing a monograph on British Actiniaria which the Council of the Ray Society has undertaken to publish shortly. Certain little-known species of vague systematic position have never reappeared since their first discovery, this usually dating prior to 1860. In such a case it is very desirable that all described forms should be procured before the appearance of a new monograph, so that an accurate species-list and correct details of distribution may be included. If any one who would care to collect living material during 1925 will communicate with me, I shall be glad to supply a list of desiderata and localities, to defray cost of postage, etc.

Some Recent Researches on X-Rays: the J-Phenomenon.[1]

By Prof. C. G. BARKLA, F.R.S.

A FEW years ago there appeared to be two, and only two, X-ray phenomena—scattering and fluorescence. One was due to the tremor, the forced vibration, set up in electrons when matter was traversed by X-rays; the other was due to the ejection of electrons from certain atoms and the subsequent free vibration of electrons within those atoms. One was governed by classical laws, the other by quantum laws.

For some years now, what is apparently a third phenomenon has been coming to light. This phenomenon has many of the characteristics of fluorescence (with the emission of characteristic X-rays). As it was found to occur at frequencies higher than those associated with the K-radiations, it was called the J-phenomenon. It has also frequently a close association with scattering, an association which led to what has been called a quantum theory of scattering. The phenomenon is, however, neither X-ray scattering nor X-ray fluorescence, as these terms have been understood; and it seems undesirable to use either term to denote what is quite distinct from both. It is almost certainly governed by quantum laws, and it is possible that its investigation will lead to some solution of the whole problem of the quantum relationships.

THE J-PHENOMENON.

The effects described as the J-phenomenon are briefly these:

As the frequency of an X-radiation gradually increases, though there is in general an increase in the penetrating power of the radiation, under certain conditions the absorption in a given substance exhibits a discontinuity, rising abruptly to a higher level, and afterwards diminishing as previously with increasing frequency of the radiation. This is very similar to the rise in the absorption in a substance accompanying the emission by that substance of a characteristic radiation.

This absorption discontinuity occurs at higher frequencies (higher penetrating powers) the higher the atomic number of the absorbing element. The discontinuities have been observed in carbon, nitrogen, oxygen, aluminium, sulphur, copper, gold, and platinum.

The sudden increase in the absorption of the rays is accompanied, when the absorbing substance is in the gaseous state, by a sudden increase in ionisation in that substance. When in the solid state, the absorbing substance emits an additional corpuscular radiation. The ejected electrons are apparently slowly moving electrons.

All these phenomena are suggestive of the emission of characteristic radiations of another series, the J series.

There are, however, a number of characteristics which distinguish the J-phenomenon very clearly from the phenomena associated with the emission of characteristic radiation of the now well-known K, L, M series. These may be briefly summarised:

1. The phenomenon is conditional on some unidentified factor or factors (possibly of intensity or superposition), whereas the only condition essential to X-ray fluorescence as previously known is that expressed by Stokes's fluorescence law.

2. The sudden changes in absorption and in ionisation appear to be absolutely abrupt, even when a *heterogeneous* primary beam is used.

3. The point at which the discontinuity occurs appears to be more closely connected with the rate of absorption of energy than with a critical wave-length (though the former, of course, depends upon wave-length).

4. The series of critical wave-lengths in the various elements cuts right across the well-known K series.

5. The change of critical frequency with atomic number is very small.

EXPERIMENTAL EVIDENCE.

The experimental facts illustrating 3 (above) are so remarkable and so entirely new, that they are worthy of description even in a short summary.

(*a*) Two beams proceeding from the same X-ray tube at the same time in different directions may have different penetrating powers. (There are various possible reasons for this; though it may be suggested that the obvious ones are not necessarily correct.) As the tube hardens up, the discontinuity in the absorption of each beam occurs, not when a particular state of the tube is reached, but when each beam, independently of the other, reaches the critical penetrating power for the substance used as the absorber.

(*b*) A heterogeneous beam direct from an X-ray tube in some cases shows no absorption discontinuity as the tube becomes harder, whereas when the same radiation is filtered and so brought to a higher average penetrating power, the discontinuity in absorption occurs at the correct critical penetrating power for the absorbing substance used. Thus the absorption of a complex beam is not the sum of the absorption of its constituents.

(*c*) Again, in some experiments, if the radiation is passed through a thin filter, as the tube hardens the absorption discontinuity does not appear; whereas when a thicker filter is used, the absorption of the transmitted radiation shows a well-marked discontinuity, and at the correct critical penetrating power.

(*d*) Further, and confirming the above, in some experiments the absorption discontinuity does not appear when *thin* absorbing sheets (absorbing only a small fraction of the radiation) are used; whereas the discontinuity appears when the absorption is measured by means of *thick* absorbing sheets.

(*e*) Transmission of a given heterogeneous radiation through successive very thin sheets of absorbing material, shows (as might be expected from the above results) that at a certain critical thickness there is an abrupt drop in the intensity of the transmitted beam; that is, the exponential law of absorption evidently breaks down and there is a sudden extinction of the primary beam. After this the absorption differs little, if at all, from what is normally expected. Whether or not the transmitted beam is truly transformed is not shown by these experiments; in experiments of another kind, however, when the sudden extinction occurs, the transmitted beam is definitely of a more absorbable type than previous to the abrupt change.

These results naturally suggest such inquiries as the

[1] A summary of the Silvanus Thompson lecture delivered before the Röntgen Society on April 1.

following: Are we really measuring the intensity of the radiation? Is a certain portion of the ionisation (used as a measure of intensity) produced by a method distinct from the remainder, and are all the phenomena above described due to this special ionisation? Is a fraction of the observed effect of the X-rays due to the combined action of a number of radiations differing in wave-length? Is a certain portion of the ionisation due to short-range electrons as distinct from the bulk of the ionisation taken as a measure of intensity?

An answer to these and many other questions is given by the results of experiments in which various methods of measuring intensity were adopted. Ionisation in air, in sulphur dioxide, and in hydrogen produced by the emission of high-speed electrons from an aluminium plate in the path of the X-rays, and ionisation produced by the high-speed electrons ejected from copper, were all used as measures of intensity. The discontinuity was observed by each method, and at the same critical penetrating power. The phenomenon thus appears to be independent of the particular method of measuring the X-radiation. We must therefore assume that the phenomenon is one in the X-rays themselves, for our only measure of X-rays is obtained from such effects.

These phenomena have been observed with radiations from many different tubes and with different anticathodes; with strong and with very feeble radiations; with narrow pencils and with wide beams; with polarised and with unpolarised radiations; with heterogeneous and approximately homogeneous radiations; with primary radiations, scattered radiations, and characteristic radiations.

Applications to the Scattering of X-Rays.

The results recorded above have many important applications, notably to the phenomenon of scattering of X-rays.

Röntgen radiation which is scattered from light elements is exactly like the primary radiation in its penetrating power (and hence its wave-length) over a long range of wave-lengths. The polarisation, distribution, and intensity of this radiation are all accounted for by the classical theory of radiation. There is no shadow of the quantum in the phenomenon. The appearance under certain conditions of a secondary radiation differing from the primary indicated the probability of the emission of a fluorescent radiation of the J series by these light elements. Compton has recently called this transformed radiation "scattered radiation." It appears that this transformed radiation is neither a fluorescent radiation nor a scattered radiation, as these terms have been understood.

The transformation observed by us is the transformation associated with what is described above as the J-phenomenon. For some reason (possibly connected with intensity), the scattered radiation appears more susceptible to the J-phenomenon than the primary radiation. The following brief statement of results obtained from experiments on scattering show that the true phenomenon of scattering may be completely masked by the J-phenomenon as described above; the results are precisely those to be expected from the application to the scattered radiation of the laws governing the J-phenomenon. They are all contrary to Compton's hypothesis. (Most of the following results were obtained in collaboration with Dr. S. [illegible] Khastgir.)

1. As the wave-length of a primary radiation diminishes, the scattered radiation remains exactly like the primary (measured by its absorbability) over a long range of wave-lengths. There is nothing even approaching the difference between primary and scattered required by Compton's hypothesis.

2. An apparent change—a difference between scattered and primary radiation—appears quite abruptly as the frequency of the radiation is increased. It is a change of the order of five or more times the error of experiment. There is no mistaking it. This well-marked difference in penetrating powers of scattered and primary radiations persists for all shorter wave-lengths. (This phenomenon seemed at first to confirm the indications of an emission of characteristic rays of the J series.)

3. Further sudden changes in the scattered radiation appear as the wave-length of the primary radiation is diminished, the difference between the secondary and primary radiations becoming greater at certain critical, though not accurately definable, wave-lengths. There are several well-marked discontinuities.

4. Using various substances to measure the absorbability of the primary and secondary radiations, the above-mentioned discontinuities occur not at the same but at slightly different wave-lengths.

5. When *thick* absorbing sheets are substituted for *thin* ones to test the character of the radiations, the discontinuity—the sudden appearance of or increase in the difference between the primary and the secondary radiations—appears earlier; that is, when the primary is of greater wave-length than is the case when thin absorbing sheets are used.

6. The wave-length at which the difference appears (the discontinuity) depends to a certain extent both upon the *material* and upon the *thickness* of the radiating substance.

7.[2] In certain selected cases, we can identify the thin layer of absorbing material in which the change occurs. Thus as primary and secondary radiations are transmitted through an increasing thickness of absorbing material, the absorptions up to a certain thickness are exactly alike (unmodified scattering). A further thin layer makes all the difference between the two. Afterwards the scattered radiation is the more absorbable. Thus we have curves showing quite definitely that an unmodified scattered radiation becomes suddenly modified by transmission through material quite outside the scattering substance. It is, of course, only by proper selection of the radiation experimented upon that this transformation can be located in this way. But this fact alone shows that the transformation is not necessarily or essentially in the process of scattering.

The importance of this result is little affected by the fact that in numbers of experiments in the Laboratory at Edinburgh as elsewhere, long series of observations show a persistent difference between primary and secondary radiations without a suggestion of equality of wave-length or of the abrupt changes referred to above.

[2] Results under section 7 were obtained in April 1924, shortly after the lecture before the Röntgen Society.

ne experiments only *appear* to indicate a change of ave-length produced by scattering. It is possible that, these cases, the J transformation occurs at the birth the scattered radiation. But facts of much greater gnificance are these :

As the frequency of the X-radiation increases we can, many cases, observe the quite abrupt transition from unmodified scattered radiation to the modified attered radiation. There is a gulf between the two hich makes the identification unmistakable and shows at some special condition is essential to the produc- on of the modified scattered radiation. We can, in lected cases, take the unmodified scattered radiation d transform it into the modified scattered radiation, en identifying the thin sheet of absorbing material hich affects the transformation—quite outside the attering substance.

These are not isolated results, nor are they of the zy, indefinite kind which some seem to suspect. The anges are of a magnitude several times the magnitude the possible error. The phenomenon has all the aracteristics of the J-phenomenon as observed iginally in primary radiations, and as briefly indicated ove.

It is not intended here to discuss either the process even the nature of the transformation involved, for ough many experiments have been made, many more e necessary before we can get a secure foundation for y theory. The phenomenon is not scattering nor it fluorescence with the emission of characteristic diation as generally understood ; it is a new—a ird X-ray phenomenon. Without committing one- lf to an opinion, it may be stated that there is the pearance of a sudden absorption of the beam followed y a re-emission of radiation of somewhat greater ave-length proceeding in the original direction of opagation. Absorption laws break down ; methods comparing intensities of radiation are no longer pplicable. This needs to be borne in mind in experi- ents upon penetrating radiations. It seems highly obable, for example, that in experiments on the sorption of penetrating X-rays and γ-rays, the trans- itted beams produce far too much ionisation for their nergy, and thus appear not to be absorbed so strongly s they really are. For we have observed sudden increases of ionisation of so much as 100 per cent. due to a very slight diminution in wave-length. Thus there seems little doubt that when penetrating X- and γ-rays are transmitted through thick layers of absorbing material, the ionisation coefficient is suddenly increased at certain points (under certain conditions the change may be gradual), and the transmitted radiation then produces a greater effect than is accounted for by intensity alone. It appears more penetrating than it really is.

Conclusions.

The broad conclusions are that under certain conditions not yet identified, but apparently depending on the rate of energy absorption, discontinuities occur in the absorption of X-radiation accompanied by corpuscular emission from the absorbing substance and ionisation when that substance is in the gaseous state. The transmitted primary radiation behaves as a transformed radiation.

No direct evidence of the emission by the absorbing substance of a characteristic X-radiation (of J series) has been obtained. If it exists it must be very feeble. What originally appeared to be a fluorescent radiation (and to others a modified scattered radiation) has been found in some cases to be merely the scattered radiation transformed by transmission through matter after its production. The radiation when observed is neither characteristic nor scattered, but is the scattered radiation after having been transformed by the J process (a process similar in many ways to fluorescence with the emission of characteristic X-rays). The necessity for critical conditions suggests obedience to the quantum laws in some form. The well-known laws of X-ray absorption break down when the critical conditions are reached.

Though it is realised that some of the results here recorded will possibly need re-statement or modification when they are tested by experiments extending over a wider range of conditions, the results already obtained are so absolutely new, so remarkable, that they seem to justify publication before a solution of the whole problem has been found. Further investigation of the subject promises to lead to some of the most interesting and important generalisations.

Historical Tradition and Oriental Research.[1]

By Prof. J. H. Breasted, University of Chicago.

It has often been remarked that the outstanding trait of the untrained mind is credulity. The rationalisation of man's views of the world has been a very slow rocess and it is still very far from a completed process. t has commonly been thought to have begun with the reeks, but its origin must be sought in the Orient in a eriod long before Greek civilisation had arisen. The dwin Smith Medical Papyrus, acquired in 1906 by the ew York Historical Society, discloses the inductive rocess of scientific investigation already in operation n the seventeenth century before Christ. For example, his document contains the earliest occurrence of the ord " brain " anywhere appearing in surviving records f the past. The word is unknown in Old Testament Hebrew, in Babylonian, Assyrian, or any of the ancient languages of Western Asia. The organ itself therefore was evidently discovered, and the recognition of its various functions was begun, for the first time by these physicians of early Egypt in the thousand years preceding the seventeenth century B.C. The observations recorded in the Edwin Smith Medical Papyrus show that its author had already observed that control of the members and limbs of the body was localised in different sides of the brain ; and the recognition of localisation of functions in the brain, mostly the work of modern surgeons and others within the past generation or two, had already begun in the seventeenth century B.C., at a time when all Europe still lay in savagery or barbarism.

There is in existence part of an original transit

[1] From a paper communicated to the National Academy of Sciences, Washington, on April 29, and published in the Proceedings of the Academy or July, vol. x. No. 7, 1924.

instrument, made, as stated by the inscription upon it, by no less a king than Tutenkhamon, in the fourteenth century B.C. It did not come from the tomb of Tutenkhamon, but was apparently made by him for the tomb of his (or his wife's) great-grandfather, Thutmose IV. (fifteenth century B.C.). This and another such piece at Berlin are the oldest scientific instruments of any kind now known to us. It was used for determining meridian time, especially at night, in order that the observer might then set his water-clock, with its 24-hour divisions, a division of the day which thence passed over into Europe in Hellenistic times, whence it was transmitted to us.

Now Herodotus reports a tradition current in his day (fifth century B.C.), that the Greeks were greatly indebted to Egyptian knowledge. This tradition has in recent times been universally rejected ; but it would seem that there was much truth in the tradition transmitted to us by Herodotus, and that its complete rejection by classical prejudice is unjustifiable.

The fact that the early Egyptian scientific worker employed an inductive method so far back as the seventeenth century B.C. does not, however, mean that he had completely banished from his mind all belief in magic or in supernatural forces. This truth has been well demonstrated for later ages by Prof. Lynn Thorndyke in his monumental volumes on "The History of Magic and Experimental Science." Undoubtedly the Greek took the longest step in freeing his mind from inherited religious and traditional prepossessions. Using astronomical observations undoubtedly drawn from Babylonia, Thales predicted a solar eclipse in 585 B.C. Astonishing as it seemed to the Greeks, there is little probability that this feat was an unprecedented achievement. What *was* unprecedented, however, was the revolutionary generalisation which Thales based upon his ability to make such a prediction. For he banished the erratic whims of the gods from the skies and discerned the sway of natural law throughout the celestial world. To tear away and fearlessly to trample under foot beliefs and superstitions which had been sanctified by age-long religious veneration demanded dauntless loyalty to his own intelligence. This first supreme enthronement of the human mind was probably the greatest achievement in the career of man.

We can pay no greater tribute to such Greek thinkers than to recognise, that although they put credulity to rout, they could not banish it altogether. It has survived with extraordinary persistence even to the present day. In modern times it was of course the tremendous significance of the discoveries of Galileo which most impressively reproclaimed the supremacy of natural law and the sovereignty of the human mind in discerning that law.

From Galileo's struggle with the church to Huxley's debate with Gladstone, the heavy guns of natural science have dealt tradition one destructive blow after another. It has been under this destructive attack at the hands of natural science that historical criticism has grown up in modern times since Niebuhr. Indeed it has been no accident that in the United States the first serious discussion of the Old Testament narratives in Genesis and Exodus was written by Thomas Cooper, who was the associate of Priestley in the discovery of oxygen. Cooper was Thomas Jefferson's appoint as first president of the new University of Virgini but in the Virginia of that period the social feeli against Cooper for having assailed the literalistic int pretation of the Old Testament was so strong th Jefferson was unable to secure his induction into offic Jefferson's influence, however, secured Cooper's appoin ment as president of the University of South Carolin where public opinion was at first not so strong again him as in Virginia. It is interesting to note that befo the end of the 'twenties, that is, less than a century ag conservative sentiment was strong enough to bri about Cooper's dismissal from the University, althou his personal popularity was such that he was prompt appointed to codify the laws of the State, and the fir legal code of the State of South Carolina was edit by this gifted representative of natural science a historical criticism.

The merciless critical scalpel which had not spar Hebrew tradition was equally unsparing in its treatme of the cherished classical heritage from Greece ar Rome. The tales of Romulus and Remus, the Troja war, and the entire cycle of legends which were link with it, were shorn away. A critical attitude of un versal negation arose. It included the whole Medite ranean and Oriental world : Rome, Greece, Hebrew Babylonians, Assyrians, and Egyptians. Historic criticism would not allow that early man at th beginning of the age of writing had ever heard a transmitted an echo from earlier ages, which, becau they possessed no writing, could only send on the story in the form of oral traditions. This attitude the historical critic may be compared with that of a observer who stands on a mountain peak, and, lookir off across a distant landscape to a dim horizon shroud in mists and cloud, insists that the intermittent glimps of mountain profiles which vaguely emerge on th far-away skyline cannot correspond to any reality. short, without ever having been himself on the grour to investigate, he denies the existence of the phanto mountains on the horizon.

The orientalist, if he be something more than philologist, may be compared with the explorer wh pushes out to that distant horizon, and is able t determine on the ground whether the phanto mountains really exist. Such investigation is, howeve relatively recent, and the historical critic could scarcel anticipate that it was coming. He seemed to be qui safe in sweeping away all early human tradition. dealt with a world of gods, demi-gods, and heroes ; was dominated by the whims and caprices of angr or jealous divinities, and it was filled with impossib wonders and prodigies. How could a soundly critic historian accept narratives which seemed so manifestl impossible ? We must grant that in the circumstanc rejection complete and unqualified seemed the onl safe course.

Such critical negation was supreme when, fifty yea ago, archæology began to reveal with startling vividnes the facts and the daily equipment of human life in th very ages with which the rejected traditions deal In the seventies of last century the excavations of a untrained observer from the outside disclosed a astonishing vision of pre-Greek civilisation at Tiryns Mycenæ, and Troy. The incredulity with which thes

iscoveries of Heinrich Schliemann were greeted by the assicists was highly characteristic. His excavations covered and exhibited to the incredulous eyes of the estructive critics the whole material equipment of aily life from the very age of the Trojan war (or wars), nd from the very city in and around which it was aged.

Similar revelations, involving far earlier periods of me, rapidly disclosed the successive stages of the uman career from a remote antiquity, reaching well ack of the beginnings of the world as dated by an lleged "Biblical" chronology. In dealing with the raditions of these earlier ages the orientalists soon eveloped a similar school of negative criticism. Such raditional accounts were promptly thrown into the iscard. Maspero's bulky history of the oriental eoples, still a standard work on most modern library helves, tells us that Menes, the first king of the First Dynasty of Egypt, was a purely mythical or legendary igure. Nevertheless we now possess his tomb, and in ur collections at the University of Chicago we have a iece of his personal ornaments, a gold bar bearing his ame in hieroglyphic — the oldest piece of inscribed ewelry in existence. Since 1894, thousands of pre-istoric graves have been excavated along the margin f the Nile Valley, revealing to us the successive stages f human advance for many centuries before the once egendary Menes.

Much the same process is going on in the investiga-ion of Babylonian history. Even the mythical hero Gilgamesh, the original of the European Hercules, bids air to emerge at last as a remote city king of early Babylonia, who gained a reputation for his prowess in war, until he became the typical and proverbial strong man of all ages.

The crowning disclosure in this unprecedented series of unexpected revelations has recently come from Asia Minor. Nearly twenty years ago the German Assyri-ologist, Hugo Winckler, visited the mounds of Boghaz (or Boghaz Köi—"Boghaz village") in central Asia Minor. As he walked over the ruins he kicked up with his boot heel several cuneiform tablets, lying practically on the surface. Below were piled the clay tablet archives of the Hittite "Foreign Office," the earliest of which had been lying there at the capital of the Hittite Empire since the middle of the second thousand years before Christ. The result has been the decipherment of ancient Hittite, or rather a whole group of Hittite, dialects. The War has intervened, and since Winckler's death the progress of examining this enormous body of archives has unavoidably been very slow. We owe a great debt, especially to Hrozny and Forrer, for the invaluable disclosures which they have wrung from these documents.

One of these tablets reports a war of Atreus, king of Achaia, against the king of Caria at about the middle of the thirteenth century, that is, about 1250 B.C. There can be no doubt that in this tablet we have a contemporary reference to the cycle of Trojan wars—a reference which must be regarded as an irreproachable historical source, as old as the events which it records. Thus out of the lost oriental background of Greek history in Asia Minor comes a *written* document confirming a Greek tradition, born in an age when the Greeks themselves still lacked writing. Because writing reaches further back in the Orient by nearly three thousand years than it does in Greece, we are able to confirm Greek tradition out of contemporary written sources.

It has long been recognised that in the early development of Greek civilisation the cities of Asia Minor took the lead. Thales, who lived in one of these cities, was an example of this early stage of Greek culture in Asia Minor. It is also evident that the inland background of oriental culture contributed much to this early development of Greek civilisation on the western fringes of Asia. It is out of this newly recovered oriental background that we are slowly regaining the earlier forerunners of Greek civilisation.

This contemporary reference to the Trojan war is an epoch-making revelation, which must react powerfully upon our treatment of early human traditions. It at once demonstrates that such traditions must not be thrown to the scrap-heap, but rather carefully divested of gods and goddesses, prodigies and wonders, and then examined for the nucleus of sober fact upon which the legendary tale has been built up.

As we look back upon our earliest historical horizon, we now know that the men who stood there in the grey dawn of the age of writing were able to hear echoes of a remoter past, transmitted in the form of oral tradition, of which some portion was then committed to writing and thus survived. In our modern effort to recover and reconstruct the story of man's past career, we have thus rehabilitated a new body of sources, however cautious it behoves us to be in making use of them. Not credulity alone, but also historical method, demands that we recognise these traditions, or the nucleus of fact to be drawn from them, as a body of sources to be restored to their proper chronological position in the succession of surviving evidences which reveal to us the past career of man on earth.

We are the first generation of men able to survey that career without a serious break. As we marshal the evidence for its successive stages, the humanists stand shoulder to shoulder with the workers in natural science, for as we look backward it is the materials and the methods of the geologist which confront us first. The geologist is succeeded by the palæontologist, the anthropologist, the anthropogeographer, and the archæologist. It is at this point, on the border land between the investigations of the worker in natural science and those of the humanist, that we must insert these long-discarded echoes from an age able to transmit only oral tradition, the true value of which oriental research has now interpreted to us. The Homeric songs of the Trojan war can no longer be regarded as exclusively noble literature, of purely legendary content; and, in the presence of these earliest surviving monuments of science, the Greek tradition of substantial Egyptian contributions to knowledge must not be rejected as baseless. There is every possibility that the tombs of Egypt may yield us further scientific treatises like this great Edwin Smith Medical Papyrus, and we cherish the hope that the thirty-five or forty chests, boxes, and caskets still lying in the innermost chamber of the tomb of Tutenkhamon with their seals unbroken may contain written documents.

Rotor Ships.

DURING the last few days, accounts of a new departure in ship propulsion have reached Great Britain. One vessel has been modified to illustrate the working of the new method and has operated in Kiel Harbour. The new invention represents an application of scientific principles known for many years; an early English paper entitled "The irregular flight of a tennis ball" was published in 1878 by Lord Rayleigh, using the same principle in explanation. The practical deduction from the general physical and mathematical idea is that a body like a circular cylinder, spinning about its axis and moving at right angles to it experiences a force which is at right angles both to the axis of the cylinder and to the direction of translation. The force is proportional to the product of the speeds of rotation and translation.

Herr Anton Flettner, the inventor of the "Rotor ship," uses two masts, one forward and the other aft, as pivots for two rotating drums. The drums are about 60 ft. high and 10 ft. in diameter, and are driven at 100 r.p.m. by electric motors of 9 h.p. The direction of rotation may be reversed and with it the resulting force. To see the method of application to steering, imagine the ship to be moving forward under power from auxiliary machinery with the two towers rotating in opposite directions. The forces will be athwart the ship in opposite directions and will together give a couple turning the ship. The only effect of rotation in the same direction would be to produce drift.

The most important of the claims made for the invention appears to be its capacity for extracting energy from the wind. Clearly, from what has been said above, the maximum propulsive effect from th circulation will be obtained with the wind across th ship, and it will fall off as the wind comes into th direction of motion. By changing the direction rotation of the towers and tacking, advantage can b taken of any wind, and, in a general way, the problem are of the same character as those connected wit sailing.

There are points of difference, however, which ca only be dealt with adequately on the basis of efficienc and the data so far received are insufficient for a dis cussion. Circular cylinders produce vigorous eddies i their wake, and such experiments as have been mad show that the circulation produced by rotation i imperfect; the result is a very much smaller forc across the direction of translation than is calculated and in addition there is a drag.

It is probably not generally realised that the win of an aeroplane, without rotating, is an efficient mean of producing circulation, and that the support of a aeroplane is an example of the law enunciated at th beginning of this note. The sail of a ship belongs t the same category, and from the fact that the experi mental work on circulation was executed at the Aero dynamical Laboratory at Göttingen, where this is ver well known, and that no aeronautical applications hav been made, it appears that scepticism as to the claim for high efficiency of the "rotors" is justified. Th accounts received are such that it is difficult to dis entangle achievements and hopes, but the claims fo handiness and seaworthiness, etc., may merit close attention when fuller details are to hand. L. B.

Obituary.

Sir Archibald Geikie, O.M., K.C.B., F.R.S.

THE "Long Life's Work" reviewed in NATURE of July 26 has been brought to a close. Sir Archibald Geikie passed away in his eighty-ninth year on November 10. For several years gradually failing health had confined him to the home he had made at Haslemere, but his pen was busy almost to the last, for the autobiography referred to bears the date 1924. The details of his upbringing and career, his extensive travels, the innumerable functions in which he was a leading figure, and the many friendships he made, are set out in the review in NATURE and need not be repeated, but his relation of personal experiences may now be supplemented by an account of geological achievements, which he passes over lightly. The comparative share which he and his contemporaries took in the elucidation of some of the great problems of the day requires a fuller consideration than could be given in a volume which was designed as a record of reminiscences rather than as a geological treatise.

Geikie was for many years the leading figure in British geology. His numerous original contributions to scientific journals, the charm and lucidity of his style, and not least the lasting value of his "Text-book of Geology," placed him in the forefront of living geologists. His work, unlike that of Lyell, was largely founded on the observations which he himself had made in the field, either original work for which he was alone responsible, or the work of colleagues which he had inspected in his official capacity on the Geological Survey. In either case his eye for scenery, his rapid grasp of essentials, and his facile and ever-industrious pen enabled him to record some of the greatest advances made in geology during the present era in papers which are unsurpassed for interest, elegance of diction, and lucidity.

When the Murchison Medal of the Geological Society was presented to Geikie forty-three years ago, special mention was made, in an already long list of valuable papers, to his work on the Chronology of the Trap Rocks of Scotland. He had been struck by the remarkable abundance of traces of volcanic action in past geological times as an outstanding feature in the geology of Midlothian and West Lothian. He recognised distinct vents from which lava had flowed on to the surface, or from which dust had been shot into the air, all to be buried and intercalated later on in the sediments of the Old Red Sandstone or Carboniferous formations. From this time on he tells us "the wide subject of volcanism . . . grew to hold the dominant place in my geological enquiries, leading me ultimately to pursue it far and wide over the whole of Scotland, and into every tract in England, Wales and Ireland where relics of volcanic history have been preserved. The study further impelled me in later years to visit the volcanic regions of Auvergne, the Eiffel and Italy,

ıd eventually to explore the great lava-fields of Western America" ("A Long Life's Work," p. 62). is exhaustive study of the subject found issue in a aper communicated to the Royal Society and afterards in "The Ancient Volcanoes in Great Britain," ne of those books in which he fascinates non-geological aders as well as experts by descriptions of some of the ast episodes of the earth's history, written in his own imitable style.

The controversy on the North-West Highlands is riefly referred to in the autobiography mentioned bove, but cannot be passed over so lightly in estimating eikie's share in the advance of geology. He accomanied Murchison in 1860 on a tour through the ighlands. Cambrian [1] fossils had been recognised by harles Peach in 1854 in the limestones of northestern Sutherland, and Murchison wished to extend is conclusions drawn from that discovery to the entral and southern Highlands. "I have to admit," eikie writes in 1924, "that this expedition . . . was premature attempt to solve problems which have not et been all solved . . . the true structure of the lighlands was far too complicated to be unravelled y desultory and hasty traverses of the ground. It equired to be patiently worked out by detailed mapping, uch as has revealed the complicated grouping of the ocks in Sutherland" ("A Long Life's Work," pp. 4, 85).

The Sutherland complications here referred to had eceived Murchison. The one infallible test of the elative age of geological formations is that of superosition, provided always, and this is a big proviso, that he superposition is original and not the result of the eshuffling of the formations by subsequent earthnovements. Here lay the trap in Sutherland, for trata containing Cambrian fossils were seen, not once ut repeatedly, to be directly overlain by crystalline chists, the "Upper Gneiss," as it was called in contraistinction to the Laurentian gneiss which forms the oundation of the whole region. No one making mere raverses of the area could doubt the evidence of his yes, and it was only seventy or eighty years after the irst account by Macculloch and after repeated visits y many eminent geologists that the truth was learnt. Nicol, who had accompanied Murchison in one of his isits, strongly opposed his views in 1856. He stablished the pre-Cambrian age of the Torridon Sandtone, which was regarded by Murchison as Old Red Sandstone by reason of a remarkably close lithological esemblance, and in 1858, at a meeting of the British Association, he stated his conclusion that the "Upper Gneiss" owed its position to faults. Heddle, while ıccepting much of Murchison's sequence, thought that he Cambrian strata had been dropped in by faults, and Callaway also declined to accept the natural superosition of the "Upper Gneiss" upon them. Much lepended upon the correctness of these views. The 'Upper Gneiss" extends over large areas in the central Highlands, and if Murchison had been right, all the ocks must have been regarded as of post-Cambrian ıge. Moreover, it would have been necessary to suppose that a great series of rocks had been highly metamorphosed, while the strata below them remained unaltered, with their fossils not obliterated. Space does not permit of an account of all the contributions to the controversy,[2] and I must come at once to the solution. Lapworth, in speaking of the apparent superposition, used the words "it would appear, at first sight, that his [Murchison's] theory of the sequence, so far as the Durness area is concerned, is "absolutely impregnable," but in the Erriboll region he obtained definite proof that the Cambrian beds are newer than the "Upper Gneiss." By exhaustive, systematic examination of the whole Durness-Erriboll region he determined the true sequence, and established the fact that the superposition of the "Upper Gneiss" is actually due to subsequent earth-movement on a great scale.

Geikie, who had adopted the views of his chief, when once it was brought home to him that they were erroneous, was largely instrumental in their correction. He put in hand the detailed six-inch surveying of the debated areas, and selected Peach and Horne for the work, instructing them, perhaps needlessly, "to get at the truth, regardless of anything that had been published on the subject" ("A Long Life's Work," p. 214). He himself inspected their work, under stress of mist, rain, and gale, in order to convince himself of the correctness of their interpretation. The maps of the Durness-Erriboll region confirmed Lapworth's work. They were completed in 1884, and thereupon the North-West Highlands became classic ground to geologists all the world over, not only as exhibiting overthrusting on a scale hitherto unknown in the British Isles, but also for the skill and detail of the mapping by which these structures had been recorded.

Previously to this, Lapworth had, by brilliant palæontological work, thrown a flood of light on the sequence of Lower Palæozoic rocks in the southern uplands. The sequence at Moffat, as accepted by Geikie and others, involved the assigning of abnormal thicknesses and characters to certain formations. By intensive study of the fossils, Lapworth showed that the abnormalities were due to frequent repetitions of the same strata by excessive plication. In the Girvan region also profound dislocations, folds, and inversions had obscured the original order. The succession, as Lapworth found it at the hands of his predecessors, consisted of an enigmatical group of great thickness, varying extraordinarily in petrological character and containing an admixture of fossils elsewhere characteristic of distinct formations. He left it an orderly sequence, each member of which was distinct and constant in petrological character and fossil contents over the whole area.

The share taken by each of the protagonists in this controversy now lies open to posterity for judgment. That Geikie added much to the solution of these great Scottish problems can be affirmed with confidence, but he had not been able, either himself or through others, to make those exhaustive examinations in the field of the structures and the fossils that were essential for the unravelling of the tangles. Possibly the fascination of exercising his power with the pen led him to expressions of opinion earlier than his better judgment might have counselled. He was influenced also, without doubt, by a feeling of loyalty to his chief, as well as by

[1] I use the name Cambrian here to avoid confusion. The rocks were not hen so called.

[2] A full history of the investigation will be found in "The Geological Structure of the North-West Highlands of Scotland" (Memoir of the Geological Survey), 1907, chap. ii.

a natural disinclination to abandon views to which he had committed himself in print. Our sympathies may well go out to a man who puts up a good fight for his own work, for it means that he has had his heart in it and believes in it. I am reminded of an anecdote about Ramsay (Geikie's predecessor in office), who by a rare mistake had shown upon his map of North Wales as a lava a rock that was obviously a volcanic ash. Years after, brought face to face with the rock in the field, he opened a discussion with the remark, "Whatever else is wrong, my map cannot be." True it is that in the memoir already mentioned (*v.* footnote 2), which was edited by Geikie, full justice has been done to all who took part in the controversy. It is true also that, in a preface to the original report by Peach and Horne, Geikie confessed that he had been wrong. Yet one could have wished that in his last book, in which, near the close of his life, he relates his own personal experiences, and from which posterity will judge what manner of man he was, he had taken the opportunity of expressing some more generous appreciation of the labours of his fellow-workers.

I have spoken plainly, I hope not too plainly, of the part taken by Geikie in controversies, but there remains the great mass of his original unchallenged work, which for many years to come will keep his memory fresh as one of the greatest of geologists. Outstanding among his original researches are those upon volcanic phenomena, to which reference has already been made, but his papers on the Old Red Sandstone and on the glacial phenomena of Scotland are also classics. He was the first to give a connected account of the glacial deposits of his native country, and to advocate, in advance of the general opinion of his time, the agency of land-ice as a distributor of drift. In South Wales he utilised his experience of Lower Palæozoic and Archean rocks in correcting some generalisations by Dr. Hicks, himself a pioneer in that branch of geology, but prone to impetuous solution of difficulties by calling in many a *Deus ex machina* in the shape of faults. But I venture to think that he derived almost more pleasure from the writing of biographies of men he had known and worked with, and whose characters he could portray in his own kindly way. These books not only appeal to the non-geological reader, but also provoke the expert to explore literature he might have overlooked. Geikie himself was indefatigable in delving into the earliest records of geology. The "Founders of Geology" and "The Love of Nature among the Romans," to mention but two, could only have been written by a man who had read deeply in modern and ancient literature and had remembered wisely. In his "Reminiscences," his "Sketches," and his "A Long Life's Work" his pen was not fettered by the constant endeavour to avoid the use of technical expressions, and his easy, graceful language testifies to the value of his early training in the humanities and of his appreciative reading of good authors. With his keen sense of humour he could never be dull.

As a companion he was interesting and delightful, full of experiences, and charged with racy anecdotes which could be readily drawn from him, but were never forced on an unwilling listener. During his travels he made friends everywhere and he never lost their affection. In all parts of the world where geology is known, his loss will be felt as a personal bereavement.

The career now ended has indeed been a remarkab one. Adopting geology as his life's work, witho interest and rather to the consternation of his fath he rose by his own exertions to the highest scientif posts Great Britain can offer, and received honours i numerable at home and abroad. Untiring industr directed by great sagacity was the keynote of his succes

A. STRAHAN.

MR. HARRY INNES PERKINS, I.S.O., died at Sydne on October 24, at sixty-three years of age, havin retired in 1919 after a long and useful career in th Colonial Service. The son of Major-General E. N Perkins, he was born at Simla, and educated at th King's School, Rochester. He held for a short tim a post as Clerk to the Director of Public Works i Trinidad, and at the age of twenty obtained an appoint ment on the survey staff in British Guiana, where h ultimately became Acting Crown Surveyor. In 1884 1885 he took part in an expedition to Mount Roraima and prepared a map of the mountain for the Roya Geographical Society. In 1895 he was appointe Acting Commissioner of Mines. Early in that yea his "Notes on British Guiana and its Gold Industry was published. In these notes, Perkins prophesie that valuable diamond deposits would one day b discovered in the Mazaruni, which has since becom an important diamond-producing area. While Act ing Commissioner of Mines, he served as one of th British Commissioners appointed for the demarcatio of the British boundary between British Guiana an Venezuela, and in 1901 wrote a report on the geologica features of the district traversed by the Commission In some of his geological work he was associated wit Sir J. B. Harrison, whose "Geology of the Goldfield of British Guiana," published in 1908, included con tributions by Perkins. He received the I.S.O. in 1904 and in the following year was appointed Surveyo General of British Honduras, where he later becam a member of the Executive and of the Legislativ Council.

WE regret to announce that Gerard Kalshoven Gude the authority on tropical land mollusca, died o November 8. Born in 1858, he was of Dutch parentage Acting as secretary to Messrs. Veitch of Chelsea i earlier years, he had for several decades devote himself to the study of land mollusca, contributing volume on that subject to the "Fauna of Britis India." Mr. Gude also studied and arranged th important series of Tertiary land and freshwater shell of Europe for the Geological Department of the Britis Museum. A constant visitor to the Museum, his information was freely at the service of his colleagues by whom he was greatly esteemed. He had been secretary and president of the Malacological Society o London.

WE regret to announce the following deaths:

Sir Maurice Fitzmaurice, C.M.G., F.R.S., president in 1916–17 of the Institution of Civil Engineers, and formerly a member of the advisory council of the Science Museum, on November 17, aged sixty-three.

Dr. Gustav Jaumann, professor of physics in the German Technical High-School in Brunn, and a foreign associate of the Vienna Academy of Sciences.

Current Topics and Events.

A REPORT on the "White" Indians discovered by Mr. R. O. Marsh on the Chucunaque River, to whom Mr. Julian Huxley referred recently in our columns (September 27, p. 464), appears in *Man* for November. It is the result of an examination made by Dr. F. C. Shrubsall, Dr. A. C. Haddon, and Mr. L. H. Dudley Buxton at Prescott, Ont., during the recent visit of the British Association to Canada. The party brought by Mr. Marsh from Panama consisted of two "white" boys and a girl, the parents of the girl, who are brown, and two San Blas Indians from an adjacent area. The "white" subjects, except in pigmentation, are identical with the brown in physical characters. They are very sensitive to light, and their vision is subnormal. All show rapid lateral nystagmus, and the younger boy occasional rotary nystagmus. The irides are greyish violet, with increased pigmentation at the papillary margin, and in one case a certain amount of brownish coloration. Choroidal pigmentation is markedly deficient. The hair is light golden and straight, the eyelashes nearly white. The skin is white with a rosy tint. Yellow brown freckles and blotches appear on the exposed parts. The parents of the girl are normal, but the maternal grandmother is said to have been white. The conclusion of the report is that the "white" characters are due to albinism and are of no racial significance.

THE report of the administrative council of the Empire Cotton Growing Corporation for the first full year since the passing of the Cotton Industry Act on July 18, 1923, has just appeared, and is a record of much valuable work. The Corporation is now firmly established, and at the moment its funds show an excess of income over expenditure, though if the cultivation of cotton in the British Empire should succeed as is hoped, there will soon be need for every penny. Signs of success are already visible in the rise of the exports from such colonies as the Sudan or Uganda; in the latter the crop is expected to reach 120,000 bales this season, a handsome figure, though as yet small compared to the 12½ million bales of the United States, or even to the 750,000 bales of Brazil, another country of recent appearance upon the market. It must never be forgotten in this connexion that the pioneer work in the British colonies was chiefly done by the British Cotton Growing Association, founded for the purpose more than twenty years ago. This Association is now attending more to the marketing work, leaving the propaganda, cultivation, and so on, to the larger organisation of the Empire Cotton Growing Corporation.

AMONG the most important activities of the Empire Cotton Growing Corporation at the present early stage are those recorded upon the first two pages of the annual report. By representation, protest, and otherwise, it has been largely instrumental in promoting the great Gezira irrigation scheme, which will render a very large area in the Sudan available for cotton, as well as in promoting the extension of railways in Uganda, Tanganyika, and South Africa, and in other ways. The most promising portion of the Empire is undoubtedly Africa, but cotton is much hampered there at present by lack of transport facilities. In this connexion attention may be directed to the interesting experiment described in the report; two lorries of "caterpillar" type have been sent out to Nigeria for trial upon unmade roads. It seems possible that such vehicles may prove to be available for the transport of cotton over untouched country, while at the same time consolidating the tracks upon which they move. Great enthusiasm is being shown in taking up cotton in Queensland, New South Wales, and South Africa, and fairly rapid progress is also being made in parts of tropical Africa. A considerable number of men (passed students, as well as senior men) has been sent out during the year to Uganda and elsewhere to aid in cotton work. The number of students has been increased, and a large sum has been provided for the keeping up of scientific work in various universities and other institutions. We wish all success to the efforts of the Corporation in its great Imperial task.

IN the *Times* of November 10, reference is made to a recent discovery of oil at Gabian, between Béziers and Paulhan, Dept. of Hérault, France. Within the last few years there have been several reports of the location of petroliferous deposits, mainly in central and south-eastern France, but save for the actual records of such discoveries, little seems to have been heard of any subsequent industrial developments on a large scale. From geological considerations, this is largely what was to be expected, though in the present oil-find at Gabian, if initial output is anything to judge by, prospects are better than might otherwise be anticipated. The search for petroleum throughout likely areas in France has been carried on arduously under the guidance of the Ministries of Commerce and Public Works, and in this connexion more than 12,300 acres of potential oil-bearing territory in the Gabian district have been acquired for the State. On behalf of the Ministry of Commerce, the Pechelbronn Company conducted drilling operations, which resulted in the bringing in of a well with a production of 250 gallons per hour of a fairly light oil (specific gravity 0·84). This well came in as a gusher, and it is because of its performance that considerable optimism prevails as to the future of this region of France as a productive oilfield. It is early days yet to form any definite ideas as to the possibility of this area from a commercial point of view; geologically there is much to be said against the likelihood of commercial pools being located, though the actual presence of petroleum is by no means contrary to expectation. But in this, as in other cases of petroleum occurrences in Western Europe, it is not the location of the oil which is surprising but rather the undaunted energy shown in the persistent search for economically valuable oil pools in the face of so many past negative results. Nevertheless, this discovery at Gabian is regarded as being the most important of its kind yet made within French territory.

VOLUME 68 of the Memoirs of the Manchester Literary and Philosophical Society contains an interesting account of the early domestic history of the Society, by Mr. Francis Nicholson. The Society was founded in February 1781 with 25 members, four of whom were fellows of the Royal Society and five are noticed in the "Dictionary of National Biography." Within a year of its foundation, it elected Joseph Priestley as an honorary member, and in November 1785 remitted to him 50*l*. as a tribute of respect and for "promoting and extending his philosophical pursuits." John Dalton removed from Kendall to Manchester in 1793 to take up the post of tutor in mathematics and natural philosophy at the Manchester Academy, founded in 1786 as a place of education of university standard without religious tests. On the removal of the Academy to York in 1799, he remained in Manchester as a teacher of mathematics and chemistry. He was secretary of the Literary and Philosophical Society from 1800 until 1809, when he was elected a vice-president and in 1817 president, an office he held until his death in 1844. One of the most interesting documents Mr. Nicholson brings to light in his history is a letter of Dalton's dated February 1794, in which he describes how he discovered the previous summer that colours appeared different to him from their appearance to other persons and how he was investigating the peculiarity. He never married, but this letter appears to indicate that if his head had not been, to quote his own words, "too full of triangles, chymical processes and electrical experiments, etc., to think much of marriage," he might have been.

THE Physical Society of Frankfurt-am-Main is preparing to celebrate its centenary.

PROF. M. DOELLO-JURADO, of the University of Buenos Aires, has been appointed as from January last to be director of the National Museum of Natural History at Buenos Aires.

PROF. A. S. EDDINGTON, Plumian professor of astronomy in the University of Cambridge, has been awarded the Bruce Medal of the Astronomical Society of the Pacific, "for distinguished service to astronomy."

APPLICATIONS are invited by the British Boot, Shoe, and Allied Trades Research Association, 50 City Road, E.C.1, for the posts of applied mathematician and assistant physicist. The applications should be sent to the secretary of the association.

THE Council of the Röntgen Society has decided to present the Röntgen Award for the session 1923–1924 to Mr. L. H. Clark, of the Physics Department, Middlesex Hospital, for his papers (1) "A Clinical X-Ray Balance Radiometer," and (2) "On the Measurement of X-Ray Intensity."

UNDER the Peter Le Neve Foster Trust, the Council of the Royal Society of Arts is offering a prize of 25*l*. for an essay on "The Effect of Trade Union Regulations on Industrial Output." Competitors must send in their essays not later than March 31, 1925, to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.2.

THE Stockholm correspondent of the *Times* states that after a long discussion the Swedish Academy of Sciences has decided not to award the Nobel Prizes for chemistry and physics for 1924, but to reserve them another year. It was announced recently that the Nobel Prize for medicine for 1924 had been awarded to Prof. W. Einthoven, professor of physiology in the University of Leyden.

THE October issue of *The Fight against Disease*, the official organ of the Research Defence Society, contains among other matter an interesting historical account of the discovery of the lacteals by Asellius in 1622, of Sir Charles Bell's differentiation of the different functions of the anterior and posterior spinal nerve roots, and of Claude Bernard's observations on vaso-motor nerves—all of them epoch-making discoveries in the annals of physiology.

IN many investigations concerned with the nature, transmission, and prevention of human diseases, experiments on monkeys afford the best hope of a solution. In temperate climates these animals are difficult to keep for any long periods, and to overcome this difficulty the Pasteur Institute of Paris has established a laboratory at Kindia, French Guinea, particularly for research in which the higher and lower apes are employed. A detailed and illustrated account of the Kindia laboratories is given by Dr. Calmette in *La Nature* of October 25.

THE National Union of Scientific Workers, 25 Victoria Street, Westminster, S.W.1, has recently published a suggestive pamphlet "On the Encouragement of Fundamental Research," being a report of the Research Committee of the Union. Several important aspects of research training and application are surveyed in the report, and a progressive policy is outlined. We hope to deal in a later issue with some of the points raised, but meanwhile we are glad to direct attention to the pamphlet, copies of which can be obtained at the offices of the Union, price sixpence each.

THE following officers for the session 1924–25 have been elected by the London Mathematical Society:—*President*, Prof. A. L. Dixon; *Vice-Presidents*, Prof. L. N. G. Filon, Prof. H. Hilton, and Prof. W. H. Young; *Treasurer*, Dr. A. E. Western; *Secretaries*, Prof. G. H. Hardy and Prof. G. N. Watson; *Other Members of Council*, Prof. S. Chapman, Miss H. P. Hudson, Prof. G. B. Jeffery, Prof. A. E. Jolliffe, Mr. J. E. Littlewood, Prof. A. E. H. Love, Prof. L. J. Mordell, Mr. H. W. Richmond, and Mr. F. P. White.

THE Institution Medal of the Institution of Automobile Engineers has been awarded as follows: to Dr. R. Ormandy, in connexion with the editing, checking, and preparation of the matter for the report of the Empire Motor Fuels Committee, recently published as a volume of Proceedings of the Institution; to Mr. Geo. W. Watson, for his paper on "Standardisation," which formed the subject of his presidential address before the Institution; and to Mr. H. G. Burford, for his services in connexion with the co-ordination of the relations between the Institution,

the S.M.M.T., and the B.E.S.A. This Medal, which was recently established, is awarded for any paper or similar service which may be considered likely to have a special influence on the advancement of automobile engineering.

RECENT visitors to the Museum of the Brooklyn Institute of Arts and Sciences will have noticed its congested state and will be glad to learn from Mr. A. H. Fox's Report for the year 1923, lately received, that the city has appropriated 1,050,000 dollars for the completion of two new sections of the building. It is hoped that these will be available in a few months' time. We are informed that the city has also recently completed the purchase of a house adjoining the present Children's Museum; so that institution will otherwise have more space for the admirable educational work that it conducts under the inspiring leadership of Miss Anna Gallup.

ABOUT two years ago the Trustees of the British Museum (Natural History) decided to catalogue and label all type specimens of Rhopalocera (butterflies) in the collections. Until recently many undoubted type specimens stood in the collections without any indications of their unique character. As a consequence some were discarded and replaced by "better" examples. It is, therefore, gratifying to know that proper measures are now being taken to ensure against the recurrence of such treatment. The first instalment, Part I., Satyridæ, has recently come to hand, and in it are listed some 3900 type specimens. The work was commenced by Mr. N. D. Riley, but the greater part of it has been done, under his supervision, by Mr. A. G. Gabriel. The catalogue gives the Museum number, name, genus under which originally described, original reference, sex, date, etc., of each type, and it will prove valuable to the systematist.

THE second annual report of the director of the Institute of Science and Industry of the Commonwealth of Australia covers the period from July 1922 to December 1923. It appears from it that the Institute, although established in 1920, has not yet been provided with the funds necessary to enable it to carry out the whole of its functions. The total sum available for its work in 1922-3 was only 13,900*l*., and the grant for the following year 12,900*l*. It is carrying out researches on pottery, paper pulp baking, the supply of tannin, seed improvement, agricultural pests, and stock diseases. No funds have, up to the present, been devoted to the study of the refrigeration problems which are in urgent need of solution, nor have any steps been taken to organise the information available as to ore deposits and the best methods of treatment of the ores. There is no lack of problems awaiting solution which cannot be touched until more financial aid is available.

WE learn from *Science* that at the stated meeting of the Franklin Institute held on October 15, the following medals were presented: The Louis Edward Levy Medal to Dr. Harvey Fletcher, of the Western Electric Company, New York City, for his paper on "Physical Measurements of audition and their bearing on the theory of hearing," printed in the issue of the Journal of the Franklin Institute for September 1923 (this is the first award of the Levy Medal, which is to be given annually to the author of a paper of especial merit, published in the Journal of the Institute, preference being given to one describing the author's theoretical and experimental researches in a subject of fundamental importance); the Edward Longstreth Medal to Thomas C. McBride, of Philadelphia, for his invention of a locomotive feed water heater, and to Milton Roy Sheen, of Philadelphia, for his invention of the expansion machine for tunnel construction.

THE autumn conversazione of the Natural History Museum Staff Association, which took place on November 12, attracted an unusually large gathering. Sir S. F. Harmer, the Director of the Museum, gave a short talk, illustrated by lantern slides, on the British Museum Australia Expedition. The exhibits shown included some of the more important specimens collected by the Expedition, among them being new and rare reptiles and batrachians, freshwater crustacea, mammals and birds, mainly from northern Queensland. Besides these, the general exhibits included a large number of interesting specimens recently added to the Museum collections. A selection was shown of the large consignment of mineral specimens which Dr. L. J. Spencer, while in Canada in connexion with the meeting of the British Association for the Advancement of Science, was instrumental in acquiring for the Museum. A selection of the Philip Roscoe bequest of Lower Carboniferous fossils, and also Ammonites from East Devon and West Dorset, were shown. A fruiting branch of the "Creeping Fig" was interesting for two reasons: because the plant possesses dimorphic foliage, and because the specimen illustrates a method of plant preservation by the use of copper acetate. Among the insect exhibits were insect remains found in oil-sand from Trinidad, and *Chrysops discalis*, a recent addition to the known disease-carrying Diptera. Other exhibits that may be mentioned were arachnids from Mt. Everest, from an altitude of 14,000 to 22,000 ft.; a new species of shrew from the Scilly Islands; a rare deep-water genus of Alcyonaria; skeletons of two very rare flightless birds from Madagascar; and series of specimens to illustrate the reduction of limbs and digits in lizards, and the evolution of planorbid shells in the Steinheim Basin.

METEOROLOGICAL information of considerable interest to seamen is given in the *Marine Observer* for November. Observations of various degrees of minuteness are made and supplied to the Meteorological Office by commanders of vessels in the mercantile marine and by some of His Majesty's ships; the logs of the latter are, however, always available for use through the Admiralty. In addition to the ordinary meteorological log and other means of registration, special reports are made by observers on matters and experiences of note, likely to be of interest to seamen generally, and many of these are included in the publication, together with a list of all who take any part in supplying regular information. "Wireless and Weather" data are regularly given, each monthly number containing usually some new feature, and

what is given will aid commanders materially in drawing for themselves special weather charts from wireless information, enabling them to know the weather conditions in which they are situated. An article is given on South Pacific hurricanes, prepared by Mr. H. Keeton of the Marine Division. The frequency and season of the hurricanes are dealt with, together with the tracks, rate of travel, and useful information with respect to neighbouring "hurricane warning stations." An illustration appears of the memorable escape of H.M.S. *Calliope* from Apia Harbour, Samoa, during a severe hurricane on March 16, 1889.

A BOOK of topical interest is announced for publication early in the new year by Messrs. Ernest Benn, Ltd., namely, "Radio: Beam and Broadcast, its story and patents." It is by A. H. Morse, late of the Marconi Wireless Telegraphy Co. of Canada, and purports to be the first published critical and constructive history of the development of wireless telegraphy and telephony. A feature of the work is the attention given to British and American patents.

MESSRS. Henry Sotheran and Co., 140 Strand, W.C.2, have just issued a new part of their "Catalogue of Science and Technology," namely, Part V., including VI., Physics, covering the letters S to Z, and containing a Supplement. This special catalogue of Messrs. Sotheran needs no recommendation, being well known for its valuable bibliographic notes, and the number of choice and rare books offered for sale. The new section is no exception. Copies of the catalogue are obtainable upon application.

MESSRS. Baird and Tatlock (London) Ltd., 14-15 Cross Street, Hatton Garden, London, E.C.1, have issued volume 4 of their Standard Catalogue. It is a quarto volume of 640 pages, well printed and illustrated, and covers the subjects of mechanics from hydraulics to aeronautics, heat including steam and internal combustion engines, light including radiology, sound and magnetism and electricity with their applications in industry. In order to give the users of the catalogue more liberty of choice, apparatus has been included which, although not made by Messrs. Baird and Tatlock, is guaranteed by the firm. The prices quoted represent present-day costs, and it is hoped that reductions in the cost of materials and labour will admit of their reduction in the near future; if this should be so, clients will reap the benefit. Amongst the newer apparatus catalogued we notice a universal bosshead clamp, a Langmuir condensation pump, a Duddell oscillograph, and a considerable range of wireless and X-ray apparatus.

Our Astronomical Column.

FIREBALLS.—Mr. W. F. Denning writes that a very brilliant fireball was observed from many places in Cornwall and Devonshire on Sunday, November 2, at about 10.55 P.M. A loud detonation was heard by various persons at about the same time, and the inference is that the noise was connected with the meteor. Observations are coming to hand which will enable a suitable investigation to be made and the real path of the meteor to be determined. It lit up the countryside with dazzling effect, and must have been one of the finest objects of its class.

Another object of similar kind was witnessed from the north-east region of Ireland on Tuesday, November 11, at 5.40 P.M. This fireball was remarkable for the length of its flight and its long duration. It traversed a path of about 124°, from the southern limits of Aries to near the star Cor Caroli, in about 20 or 25 seconds. The apparent size of the fireball was estimated to be about half that of the moon.

Mr. E. G. Fenton writes to say that he observed this meteor at Corbally, Limerick. It appeared in the eastern sky and moved slowly in a horizontal course from south to north. It was about four times as bright as Venus when at its brightest and of a bluish colour.

THE EFFECT OF SECULAR DIMINUTION OF MASS.—Dr. J. H. Jeans read a paper on this subject at the November meeting of the Royal Astronomical Society. It was based on Prof. Eddington's paper of last March, in which the conclusion was drawn that the luminosity of a star is simply a function of its mass, so that as the luminosity declines the mass does so likewise, through the conversion of part of it into radiant energy. Applying this to the sun, it was shown that its mass must be diminishing by millions of tons every second. This has an effect on the orbits of planets, the major axis of an orbit being inversely proportional to the mass of the central body. Dr. Jeans applied this principle to the development of the double-star systems, and found on certain hypotheses that the indicated age of the sidereal universe is of the order of 10^{14} years. This much exceeds previous estimates, and on the assumption that planetary systems arise from the close appulse of two suns, it is no longer necessary to assume that such systems are extremely rare. On the greater time-scale they might be expected in a large percentage of cases, especially as the stars were presumably closer to each other in early days.

Dr. Jeans further showed that motion in equiangular spirals would arise if the central body were losing mass very rapidly. This would, however, imply much higher brilliance in the central regions than that found in the spiral nebulæ.

THE DOMINION ASTROPHYSICAL OBSERVATORY, VICTORIA, B.C.—The output of work from this observatory has been of such interest and importance that many will welcome the detailed description of the 72-inch reflector that appears in the *Observatory* for November. There was great good fortune in the safe arrival of the disc from the St. Gobain factory, as it left Antwerp only a week before the outbreak of War. It has a central aperture 10 inches in diameter for use with the Cassegrain mirror. The principal focal length is 30 feet, that with the Cassegrain mirror 108 feet.

The arrangements for mounting and supporting the mirror, for keeping the temperature constant, and for giving the telescope large and small motions (which are effected by electric motors) are fully described and appear to be admirably efficient. There is a special car for removing the mirror for resilvering, which is done about three times a year.

The spectroscope is attached below the mirror, being used with the Cassegrain mirror. One, two, or three prisms can be used. When three are in use, the star spectrum is about 4 inches long.

Some important results on radial velocities, spectroscopic parallaxes, and the O type stars have already been obtained and published.

Research Items.

THE AMORITES.—In the current issue of *Ancient Egypt*, Prof. Sayce adduces further arguments for identifying the Amorites with the Mitanni rather than with the Western Semites as usually assumed. The geographical evidence is that the early Babylonians called the inhabitants of the plateau on both sides of the Tigris Subaru—"The Highlander," and that a portion of this territory came to be called the land of the Murrû after the Mitannian occupation. The historical evidence is that the earliest known king of the Amorites, Aqwaruwas, bears a Mitannian name. In the Tel el-Amarna age, Mitannian names are still mixed with Semitic. The philological argument is based upon the identity of Murrû as used by Sumerians for "Amorite" on one hand, and by the Mitannians and Hittites on the other, as the name of the Mitanni country, Amurru with the prothetic *a* appearing only in the Semitic languages. The argument from ethnology is that the Mitannians, speaking an Asianic language, originated in Asia Minor and belonged to the white races of Asia Minor and Europe. Hence they appear in the Egyptian monuments as blond, tall, long-skulled, with blue eyes and black or red-brown hair; they may be connected with the Libyans, the Berbers of to-day. They were the precursors of the Hittites in Palestine and Syria, and possibly represent the dolichocephalic neolithic population of Palestine. Their penetration to Babylonia in the semi-mythical age may explain why the Sumerians distinguish themselves from the earlier inhabitants as "the black-headed" race.

AGRICULTURAL RITES AND THE KINGSHIP.—Sir William Ridgeway, in a communication to the Cambridge Philological Society, (Proceedings CXXIV.-XXVI.) criticises the methods of Manhardt and Frazer as applied by Miss Philpotts, Miss Jessie Weston, and Dr. B. Malinowski. In the case of Miss Philpotts, he shows that the evidence relating to kings in early Scandinavia points to their being, not god-kings, but war-kings. The absence of weapons in the burials is the practice of the later Iron Age, and no warrant for the assumption that they were the graves of temple kings. There is no evidence for a fertility drama. The performances interpreted in this sense are part of the rites of Frey, the king to whom the Scandinavians believed they owed good harvests. They thus fall into line with dramatic performances in other parts of the world in honour of ancient kings and chieftains. Miss Weston maintained that Tummuz could not be regarded as ever having been a man; yet it had been shown that in the first two dynasties of Kish and Erech "gods mingled with men on earth" and Sargon of Agade began his career as a cup-bearer of a deified king of Kish. Dr. Malinowski, while asking how magical influence can grow into political power, thinks that he has found in Eastern New Guinea a situation such as that postulated by the "Golden Bough." In each community is a garden magician, the head man, who performs his ritual for public benefit. But he gives no account of the machinery by which the chief promotes fertility. In the ancestor-worship of China, Japan, India, and elsewhere, and in New Guinea itself, we have the machinery. It is clear that ancestral spirits are held to control the crops. Further, in the account of the Trobriand chief, it is not shown what is the basis upon which the position rests. It is not magic, as the chief "has the best sorcerers at his command"; but it is apparent from Dr. Malinowski's statements that he is a military potentate. He and his ancestors owe their high rank to personal prowess.

FAUNA OF THE PEAT MOOR.—Complementary studies to those of the botanist upon the characteristic vegetation of peat are now in progress by the zoologist, and a preliminary descriptive account with lists of species is published by O. Harnisch in the *Biologisches Zentralblatt* (vol. 44, pp. 110-127, 1924). The author points out that his results are in agreement with the generalisation that an extreme habitat tends to be occupied by relatively few species represented by very large numbers of individuals, but he has also a number of interesting species to record which, though perhaps localised to this habitat, occur relatively rarely. He directs attention specially to the characteristic Rhizopod fauna associated with sphagnum, which he regards as the oldest element of the characteristic moor fauna.

VARIEGATION IN LEAVES.—As a result of the study of chlorotically variegated leaves, Seigo Funaoka proposes the following classification of the various forms (*Biologisches Zentralblatt*, 44, pp. 343–384, July 1924), based upon anatomical investigations. I. Variegation without modification of structure, including (1) periclinal chimæras, (*a*) white over green, and (*b*) green over white; (2) mosaic (aclinal) variegation, (3) variegation with gradual transition zones. II. Variegation associated with structural modification, of which two types are distinguished, (*a*) *Richardia Elliotiana*, neither palisade nor spongy parenchyma of the green leaf takes part in the formation of the white areas; (*b*) *Euphorbia marginata*, spongy parenchyma forms the white variegated region, the green spongy tissue of normal area passing over into white tissue in a brief transition zone. In an earlier number of the same journal (pp. 309–336, June 1924) Otto Renner studied the variegated mottling of Œnotheras of hybrid origin. He concludes that the differences in chromatophore structure must arise through mutation, and that we have to reckon with plastids and cytoplasm in problems of heredity, as well as with the cell nuclei.

THE SEDGE *CLADIUM MARISCUS* IN NORWAY.—One of the rarest plants in Norway is this sedge, which has so wide a distribution in South, West, and Middle Europe. Though it has occasionally been mentioned from the time of Bishop Gunnerus, great doubt attaches to all the determinations, and the only certain record is that by R. E. Fridtz, who, in 1871, found it near Kristianssand. In 1922, Dr. Jens Holmboe was so fortunate as to chance on it in a little tarn called Tveitavatnet, near Lervik. Here it grew at the end of a small promontory of sphagnum and other bog plants, and was itself associated with *Menyanthes trifoliata* and *Lysimachia thyrsiflora*. The underlying rock is a micaceous shale, but limestone crops out not far away. In "Bergens Museums Aarbok" for 1922–23, Dr. Holmboe seeks to trace the origin of these occurrences by a consideration of the fossil evidence. He concludes that, like *Hedera Helix*, Cladium entered Norway from Southern Sweden, where it already existed in late Glacial times, as the climate grew warmer. It then attained in the south and south-west coast districts of Norway a wider distribution than at present. Whereas the ivy is still stretching northwards along the west coast and cannot be said to have reached its possible limits, Cladium long ago reached its climatic boundary, and has since then shrunk to the couple of relict-occurrences herein noted. These conclusions may be commended to students of the "Age and Area" hypothesis.

STRUCTURE AND METAMORPHOSIS IN THE HIGHER DIPTERA.—In the case of the Cyclorrhapha, or higher Diptera, the characters separating most of the families represent but comparatively trivial departures from a uniform type of structure. The thorough elucidation of the morphology and development of a single well-chosen example will largely explain the features common to an enormous assemblage of species. The economically important apple maggot (the larva of *Rhagoletis pomonella*) is selected by Mr. R. E. Snodgrass with this object, and he has recently published (*Journal of Agricultural Research*, vol. xxviii., No. 1, April 1924, 36 pp., 6 pls.) an account of his conclusions which is worthy of consideration by students of insect morphology. The apple maggot lives a concealed existence within the fruit of the apple, safe from enemies and surrounded by the abundant pulp which serves as its food. Mr. Snodgrass suggests that the ancestral larvæ took to living in mud or stagnant water and, in adaptation to this environment, they developed a pair of secondary dorsal spiracles at one or both extremities of the body in connexion with the dorsal longitudinal tracheal trunks. The primitive spiracles associated with the lateral tracheal trunks became closed: their former presence is indicated by the functionless stigmatic cords which have been noted in several diverse types of dipterous larvæ. With further study it is likely that these vestiges will be found to be universally present. This adaptive change outlined by Mr. Snodgrass is found in all larvæ of Cyclorrhapha, and it is evidently advantageous since it has fitted them for varied modes of life. The larvæ of the higher flies therefore discard the primitively lateral spiracles and develop breathing-organs in relation with the dorsal tracheal trunks. The pupa retains the anterior spiracles of the larval system while the imago discards the larval spiracles and returns to the primitive or peripneustic tracheal system. Attention may also be directed to the interpretations given of the development of the larval pharynx and mouth-hooks, the pupal envelopes and the rôle of phagocytes in histolysis.

GEOLOGY AND GEOGRAPHY OF ARCTIC CANADA.—Some important geographical and geological work along the Arctic coast of Canada is published in volume xi. of the Report of the Canadian Arctic Expedition, 1913–18. The first part is a report by Mr. J. J. O'Neill on the geology of the coast west of Kent peninsula, including the Mackenzie delta and the valley of the Rae and Coppermine rivers. From his study of the deposits of the Mackenzie delta, Mr. O'Neill is inclined to believe that they are derived from material furnished by the Keewatin ice-sheet. The river brought these deposits to the coast and built them up at a rate greater than land was being lost by submergence. The growing delta was thus a barrier to the encroachment of the sea into the Mackenzie valley during the undoubted post-glacial submergence of the coast. A section of the report deals fully with native copper deposits in Arctic Canada. Vague reports of these occurrences have been circulated for many years, and it is now definitely known that deposits of native copper occur in the Coppermine valley and Bathurst Inlet. It probably is to be found also in central Victoria Island, and in Prince of Wales Island, and quite possibly in other places. It appears chiefly as amygdaloidal copper near the surface of lava flows. Mr. O'Neill goes on to discuss the commercial value of the deposits. The second part of the volume is devoted to geographical notes on the Arctic coast with a history of previous work by Messrs. K. G. Chipman and J. R. Cox. The volume contains a geological map of the coast between Darnley Bay and Bathurst Inlet.

METEOROLOGY AT SAMOA.—Reports of the weather at Apia Observatory, Samoa, for the years 1921 and 1922, together with a Summary of the Meteorological Observations for 1890 to 1920, by Dr. G. Angenheister, have recently been received. The annual reports give hourly observations of magnetic declination and of horizontal and vertical intensity with the monthly means for each hour. The seismological reports give a catalogue of earthquakes registered at the Observatory during the year. The annual report for 1921 gives only two pages to meteorology, the summary being of a very general character. In the report for 1922 daily meteorological observations are given. The summary of meteorological observations for the years 1890–1920 is very complete, and monthly means for each year are regularly given, together with the number of rainy days and the number of days with thunderstorms. In describing the climate of Samoa, it is mentioned that Samoa is exposed to the south-east trade wind, interrupted by westerly and northerly winds from December to March during the rainy season. The annual amount of rain increases very considerably with altitude, the mean increase being 18 per cent. per 100 m. The daily variation in the amount and duration of rain is, on the whole, semi-diurnal, with maxima in the morning and evening. In the trade-wind season there is only one maximum, at about 4 P.M. Observations are reported to show the 3-year period and the 11-year period. The instruments are supplied by the Seewarte, Hamburg. Numerous references are made to previous meteorological discussions of observations at Samoa, but no mention is made of observations in the years 1862–5 from instruments supplied by the Meteorological Department of the Board of Trade in 1861. These observations were taken by Mr. J. C. Williams, British Consul at Samoa, at the Consulate at Apia, a discussion of which was published in the Quarterly Journal of the Meteorological Society for July 1879.

SLOW AIR VIBRATIONS FROM LARGE EXPLOSIONS.—In the *Comptes rendus* of the Paris Acad. Sci., Oct. 6, M. P. Villard describes the register of air vibrations obtained at Paris by Dufour when the La Courtine explosions took place. Very considerable amplitudes were recorded with a frequency of about a second, the approximately sinusoidal motion lasting for about three seconds. This is about four octaves below the lowest audible note; there was no trace of audible frequency. It appears that, in all cases when large quantities of explosive are involved, the low-frequency waves, even at small distances, are much more important than the sound waves, which can be regarded as an accessory phenomenon. The author on one occasion was 1800 metres distant from a very violent explosion in an explosives factory; the sound heard was loud, but by no means deafening, being comparable with a short, loud thunder-clap. At the same time, although there was a calm, a breath of air was felt on the face, similar to that produced by the motion of a fan. This was the compression half wave of a movement with very low frequency, the amplitude being apparently several centimetres, of course enormous compared with that of a deafening sound. On another occasion a French window, which was unfastened, was opened about 10 cm. by the wave of compression of a similar explosion. On both these occasions windows were broken in the immediate neighbourhood by the pressure difference between the air outside and inside the buildings.

THE PLASTICITY OF ROCK SALT IN WATER.—This subject is discussed by Messrs. W. Ewald and M. Polanyi in the *Zeitschrift für Physik* of September 20. Various observations have recently been made on the

plasticity of wet rock salt; but the theories proposed to account for it do not agree. The authors have made additional measurements of the plastic bending of strips of rock salt in water, and conclude that the effect is due to a lowering of the elastic limit, which commences immediately in contact with water, and ceases when the surface is dried, or when the water is saturated with salt. The effect is observed, though not quite so strongly, when the upper compressed side of the bent prism is wetted. If only the lower side is wetted, the plasticity is scarcely observable (the prism or rod is supported at the ends and weighted in the middle). Apparently, at ordinary temperatures, the essential part of the resistance to change of form resides in the surface, and during the solution of the surface layers this resistance is removed. There is slip along the rhomb dodecahedron surfaces, and thus the layers of slip come to the surface, and fine steps or slip lines are formed. In the normal surface, the slip layers are locked in place. The breaking load was increased tenfold under water; this increase in strength is brought about by the lowering of the elastic limit. It seems to be possible to approach the molecular strength of rock salt, as given by Born's lattice theory. The subject is also discussed in a communication by Prof. A. Joffé, M. Kirpichewa, and M. Levitzky, which appeared in NATURE of March 22, p. 424.

SEASON-CRACKING OF BRASS.—The issue for October 10 of *Die Naturwissenschaften* contains an article by W. Masing on this subject. It has been shown by Moore and Beckinsale that the internal stresses due to severe cold-working, which are the cause of season-cracking, may be removed by annealing at a temperature much below that at which the brass is appreciably softened, and this has now become a usual practice. Thus annealing a 70 : 30 brass at 275° C. will remove internal stresses so that cracking no longer takes place on immersion in a solution of mercurous nitrate. The new experiments show that as the degree of cold-working increases, the liability to crack increases up to a maximum and then diminishes. This is explained by the fact that the action of the mercurous salt, as well as the failure in use, always proceeds along the intercrystalline boundaries. In a very severely cold-worked metal the structure becomes more confused, and it is suggested that chemical action along boundaries is thereby hindered. A different kind of cold-working, however, may again cause cracking. For example, a brass which has been reduced 40 per cent. in section by cold-rolling no longer cracks under the test, but if bent or pressed into a dished form, the liability to cracking reappears. This may be explained on the basis of present views as to the fibrous structure imparted to metals by rolling, and revealed by X-ray analysis. Masing also endeavours to distinguish between gross internal stresses of this kind and microscopic distributions of stress, which he regards as responsible for increase of hardness, the latter only disappearing at a much higher annealing temperature.

FORMATION OF CRYSTALS.—In order to prove that the study of crystals is not only of academic interest, but has also important practical applications, it is sufficient to note that the Chemical Engineering Group of the Society of Chemical Industry has thought it worth while to persuade Mr. T. V. Barker of Oxford to present to it a paper on "The Development and Formation of Crystals" as a companion to a more directly utilitarian paper by Mr. H. Griffiths on "Mechanical Crystallisation" read on October 23. The latter paper is of interest because it shows that the general public has realised that a well-crystallised product is generally chemically pure (although it might contain isomorphous impurities), whereas a powder may be impure or even deliberately adulterated to any extent. It is, therefore, possible to secure much higher prices for a "pea crystal" quality, in which each crystal is a separate entity, than for a crushed aggregate such as is generally supplied when the traditional processes of "uncontrolled" crystallisation are used. In order to obtain individual crystals of uniform size, it is necessary to make use of "controlled" crystallisation, and special plant (usually a trough which can be rocked) has been devised, in which the rate of cooling and velocity of flow can be varied in such a way as to produce the desired effect. From the point of view of the consumer, it is eminently desirable that these methods should be developed as fully as possible, since there is no other method by which the uniformity and purity of a crystalline product can be so readily established.

THE POSSIBILITY OF THERMAL DISTURBANCE IN MICHELSON'S EXPERIMENT.—M. E. Brylinski has shown that, if a source of heat were situated in a definite position in the laboratory, such that differences of temperature of from 0·01° to 0·001° C. were produced between different parts of the apparatus, periodic phenomena similar to those observed by Miller in 1921 would be observed when the apparatus was slowly turned about its axis (*C. R. Paris Acad. Sci.*, Sept. 22). Such differences might easily result if one wall were warmer than that opposite, or might be due to the presence of the observers. It appears that the only way to obtain more precise results in the experiment would be to use a revolving table of invar. This would reduce the disturbances observed with Miller's cast-iron table to about one-tenth. It would be necessary to shield the apparatus from the earth's magnetic field, or to allow for its effect upon the invar table.

ACIDS, BASES, AND SALTS.—Prof. E. C. Franklin, in the October number of the Journal of the American Chemical Society, has an interesting paper on acids, bases, and salts, in which the old theory of types is revived and extended. Oxygen, sulphur, nitrogen, the halogens, and even carbon are acid, base, and salt-forming elements in the sense of Lavoisier's theory. Aquo-acids, etc., have analogies in the H_2S and NH_3 types; hydrazoic acid, formulated as $H-N=N\equiv N$, is related to ammonia as nitric acid, $H-O-NO_2$, is related to water, and the two acids have many properties in common. Many reactions in liquid ammonia are explained on this scheme. Hydrocyanic acid is formally ammonocarbonous acid, namely, NH_3, in which two atoms of hydrogen are replaced by the negative divalent carbon atom. Although zincates and plumbates are hydrolysed, the corresponding ammono-salts are readily obtained crystallised from liquid ammonia, by the interaction of metallic amides with potassium amide. The paper is full of interesting and ingenious suggestions.

FORMS OF MERCURIC OXIDE.—Although the red and yellow forms of mercuric oxide are generally supposed to differ only in fineness of division, the experiments of E. Cohen on the electromotive force of a cell composed of mercury in contact with the two forms in an alkaline solution led to the result that they are allotropic forms. The X-ray spectra of the two varieties have now been determined by G. R. Levi, who in the *Gazetta Chimica Italiana* for September shows that the crystalline forms of the red and yellow oxides are identical. Two photographs of the spectra are reproduced, which leave no doubt that the forms are not different modifications, and the usual theory appears to be completely confirmed.

The Trans-Canadian Excursion of the British Association and the International Mathematical Congress.

THE Toronto meetings of the British Association and the International Mathematical Congress in August were followed by an excursion from that city to Vancouver and Victoria and back. About 360 persons took part in it, mainly members of the Association from Great Britain, but including about two dozen members of the International Mathematical Congress from European countries, and a few Canadians and Americans. The excursion was generally voted a wonderful success and a most enjoyable and memorable experience. From a collection of notes and impressions from various sources, it is now possible to visualise something of its wide scientific interest.

The outward journey passed through the mining and agricultural districts of northern Ontario, and proceeded, by way of Winnipeg, Saskatoon, and Edmonton, to Vancouver, following the route of the Canadian National Railway, with the exception of a stage in northern Ontario on that of the Timiskaming and Northern Ontario Railway. The return journey from Vancouver was made over the Canadian Pacific Railway through the famous mountain scenery of British Columbia, and by Calgary, Regina, Fort William and Port Arthur, and Sudbury, to Toronto. The whole excursion represented 5396 miles of travel by rail; it lasted from August 17 until September 4, for almost the whole of which period the two special trains were the dwelling-places of the travellers, and the comfort of the provision made for them by the two great railways is attested by the absence of expressions of distaste for this mode of life, the habit of which was soon acquired. Moreover, the time-table of the excursion was arranged with extraordinary skill in regard to viewing points of interest, passing quickly over stages of least scenic attraction, and affording reasonable periods for rest. The generosity of provincial governments and the local committee in Toronto rendered it possible to make the journey at exceptionally cheap rates.

The excursion offered a measure of scientific interest in every department, though perhaps geologists, botanists, zoologists, and agriculturists found the widest scope. Quite apart from formal arrangements, botanists and entomologists were most conspicuous in their activities whenever the trains stopped at station or crossing, and it was possible, for however brief a period, to get out of them; the freedom of the Canadian railways in this respect was appreciated by all as a mere relaxation from travel, but it also afforded real opportunities for collecting. The economic and industrial activities of the provinces traversed; the inhabitants and conditions of life in town and country; the architectural and other developments in the greater cities, especially as realised by those who had previously visited them—these features, together with the natural beauties of the Dominion, afforded sufficiently varied interest for all the trains' company, and an enlargement of their scientific horizon. Nothing impressed the visitors more than the lavish ground-plans and beautiful buildings erected for such institutions as the Universities of Saskatchewan at Saskatoon and Alberta at Edmonton, and the Manitoba Agricultural College near Winnipeg, to which must be added the new site and designs for the University of British Columbia.

With these developments in view, it can scarcely be mere accident that the reception of the party in the visited cities differed materially from that encountered in 1909, when an excursion to the West was made after the Winnipeg meeting. Be it said at once, the high quality of Canadian hospitality does not vary. But the phase of speeches confined to words of welcome and imperial sentiment (things however admirable in themselves), the phase of frank confession that science and its aims were not understood, the phase of the triumphal arch and the town band—these seem to have passed away. Instead, the party on the present occasion was received with words which indicated a real appreciation of its mission; the scientific problems which are most closely allied with Canadian progress were clearly pointed out, and visiting scientific workers were invited to inspect and participate in the results of Canadian research. From every principal stopping-point came requests for some form of scientific communication from members of the party, and in two instances, as will be seen, there were actual sessions of some of the Sections of the Association.

Parties of geologists and botanists left Toronto in advance of the main body, to spend additional days in northern Ontario in investigation respectively of the mineralogy and the forest and plant phenomena of that region. The main body viewed the mines and process of extraction at Cobalt, Kirkland Lake, and Timmins, and the power plant and paper mills at Iroquois Falls, with its "garden city" separated by many miles of forest from any other considerable centre of population. Agriculturists left the trains at Cobalt for a short run by motor-car through a portion of the "clay belt," to view the recent extension of farming there and to visit the Dominion Experimental Farm. At Swastika, some of the members of the Anthropological Section called upon a family of Londoners, whose improved circumstances since emigration greatly impressed them.

At Winnipeg, Man., nearly the whole party was entertained at the Manitoba Agricultural College; economists and others visited the grain exchange; a geological party went to Stony Mountain to study the Upper Ordovician rocks of the district, and a party of engineers and others was taken to the municipal hydro-electric plant at Point du Bois, 78 miles from the city, incidentally viewing some interesting features of Galician and other settlement in the district.

At Saskatoon, Sask., proceedings began with the formal opening of the new chemistry building in the University of Saskatchewan. Sectional sessions then took place, in chemistry with a discussion on photosynthesis, in zoology and agriculture jointly on the subject of animal diseases, and in geology. Agricultural and experimental grounds and stock-yards, the clay deposits of the neighbourhood, and other features of scientific interest were seen, and members interested in overseas settlement saw something of the homes of the people. In the evening a public lecture was given by Dr. E. E. Slosson on photochemistry and modern civilisation.

At Edmonton, Alta., there were sessions of the Sections of Physics, Geology, and Botany and Agriculture (jointly). Special geographical, geological, and agricultural parties were formed to see things of particular interest to them. In the evening a public meeting was held in the convocation hall of the University, when addresses were delivered by Sir John Russell, Sir William Beveridge, and Dr. J. S. Flett. Some of the botanists left the main excursion at Edmonton for a journey by motor-car through central Alberta and thence into the mountains, rejoining the rest at Banff.

The main excursion, after leaving Edmonton, called at the mountain resort established by the Canadian National Railway in Jasper Park, where the members were guests of Sir Henry Thornton, general manager of the railway. At Vancouver and Victoria, a most interesting and varied programme was arranged. Stanley Park, the Fraser lumber mills, the Capilano Canyon, a settlement of Squamish Indians on the north side of the harbour, the beautiful fiord of Howe Sound, with the Britannia copper mines above it, and the power plant at Lake Buntzen were among the points visited from Vancouver by members concerned with their several scientific interests; while at Victoria the astrophysical and meteorological observatories, the museum, some old Indian village sites, and the beauties of Butchart's Gardens and the gardens of Government House, with several localities of botanical interest, were inspected. A number of lectures were given in Vancouver at public meetings or to societies and clubs, the speakers including Prof. G. W. O. Howe on radio-telegraphy, Dr. A. W. Borthwick on forestry, Prof. W. T. Gordon on gem stones, Prof. W. W. Watts on buried landscape, Dr. and Mrs. Shrubsall on physical and mental welfare, and Dr. Ivy Mackenzie on physiological discoveries of importance to the man in the street. The president, Sir David Bruce, met members of the Vancouver Medical Association. Mr. O. H. T. Rishbeth gave a lecture on modern geography at New Westminster. Marine biologists visited the well-known station at Nanaimo.

Three beautiful days were spent on the mountain section of the Canadian Pacific Railway, with calls at Glacier, Lake Louise, and Banff, and ample opportunity, thanks to the provision of open observation cars, to view the scenery between these points. A small party paid a private visit to the ranch of H.R.H. the Prince of Wales, near High River, Alta. The main party called at Calgary, Alta., where the oil refineries and other industrial establishments were seen, and at Regina, Sask., where addresses were delivered by Prof. D'Arcy Thompson, Sir Thomas Holland, and Dr. Marion Newbigin. From Kenora, Ont., trips were made on the Lake of the Woods, the limnologists working tow-nets and the geologists examining some of the islands. At Fort William and Port Arthur, the twin ports at the head of Lake Superior, arrangements for handling the grain export from the west were shown, and a geological party viewed the interesting features of Mount M'Kay and the vicinity. Brief opportunities for further field work were afforded by halts on the fine northern coast of Lake Superior, and the scientific investigations of the journey ended with the inspection of nickel and copper mines at Sudbury, Ont.

In this short narrative, no specific reference has been made to the generous hospitality extended to the travellers at every point by public bodies and private individuals. Luncheons and dinners, always admirably arranged, afforded an opportunity for general intercourse which was impossible in the dining-cars; and fleets of private motor-cars were placed at the disposal of the visitors in every city. All who took part in the excursion owe unqualified gratitude to its organisers and to those who made them their guests.

Pigments, Varnishes, and Building Stones.[1]

Early Methods of Oil Painting.

THE evidence to be obtained from ancient manuscripts as to early methods of oil painting has been re-examined. From this it is clear both from the manuscript of Theophilus and the manuscript of Eraclius that the properties of such drying oils as linseed oil and walnut oil were thoroughly understood so early as the twelfth century, if not earlier, and their preparation in a suitable condition for a painting medium and their use for this purpose.

The methods used in their preparation differ very little from the best practice of to-day. The refining and bleaching of the oil and the use of driers was well understood, and there was no indication in passing from these earlier recipes to those of the fifteenth century that any new discovery of importance was made at the time of the brothers Van Eyck. Passing to later times, Vasari directs that pigments are to be ground in walnut oil or linseed oil, and this is all that is necessary, and he recommends the use of walnut oil as less liable to darken with time.

Many recipes for varnishes are given, and as neither spirits of turpentine nor alcohol were available in commercial quantities until the end of the fifteenth century, these varnishes are what we should now describe as oil varnishes, consisting of resins dissolved in hot oil. The natural balsams of the pine, resin, mastic, and sandarac, often all mixed together, were used in their preparation, the proportion of resinous material to oil being very high, and the varnishes consequently being very sticky and having to be heated and rubbed on with the hand. Spirit varnishes corresponding to the mastic varnishes of to-day are found in the sixteenth-century and later recipes.

The evidence of the accounts preserved at Ely and Westminster shows that both oil and varnish were used in painting on walls during the thirteenth and fourteenth centuries, this being the northern tradition, while the Italian tradition was the use of egg as a medium. There is no indication in these recipes of any special secret differing from what we know to-day; but it has been suggested by Prof. Berger and others that the early method of painting in the fifteenth century may have been with an emulsion of varnish or oil with yolk or white of egg, and two recipes, one in a Venetian manuscript of the fourteenth century and one in a Bolognese manuscript of the fifteenth century, are quoted in support of this theory.

It may be admitted that if these early painters wished to paint in varnish instead of in oil, they would have had to blend the varnish with white or yolk of egg to make it into a workable medium, and the question is worthy of further inquiry.

These early pictures were painted on a wood panel sometimes covered with strips of linen and coated with a gesso made of parchment size and whitening or plaster of Paris which had been soaked in water until it lost its binding properties. Recent experiments carried out by Mr. Thompson at the Heriot-Watt College, Edinburgh, on an old sixteenth-century panel, have revealed the fact that this panel was coated with a non-absorbent gesso upon which a very thin layer of absorbent gesso was laid, so as to ensure the binding of the oil to the surface of the gesso and, at the same time, preserve from staining the pure white surface of the gesso below. On this pure white gesso panel the picture was drawn in detail, and laid out either in monochrome or partly in colour with pigments probably mixed with size, and upon this the pigments ground in oil or, it may be, an emulsion of varnish and egg were laid, care being taken to paint the high lights very thinly as compared with the rest of the picture. In course of time the oil yellows and

[1] From lectures delivered on November 12, 13, and 19 in a course of six lectures to the students of the Royal Academy, London, by Prof. A. P. Laurie, professor of chemistry at the Academy.

the pigments, more especially the white lead, get more translucent. By painting the picture in this way, the artist ensures that the increased translucency of his white lead will correct the yellowing of the oil, owing to the white light reflecting from the gesso, and that his contrast of light and shade will be maintained owing to the laying out of his picture on the white gesso surface with pigments mixed with size, and owing to the fact that his high lights are thinly painted.

There is much more yet to be discovered as to these early methods, and the question as to whether varnish, emulsion, or oil was used has still to be finally cleared up; but we are, at any rate, increasing in our knowledge of their general methods of procedure.

Modern Pigments.

The pigments used by the artists of to-day can be classified into those that can be regarded as unchangeable, those that are moderately permanent, and those that are fugitive. This classification is based in the first place on the work done many years ago by the late Sir William Abney, but since then a good deal of additional information has been accumulated, and the leading artists' colourmen firms have themselves directed a considerable amount of attention to the subject, so that it is now possible to make a fairly sound classification of pigments suitable for oil painting, a more limited list for water-colour painting, and a still more limited list for fresco.

At the same time, there are a certain number of pigments which require further investigation, as their permanency seems to depend upon the method adopted in their manufacture, and they must at present be put on the doubtful list. These include the pale cadmiums, unless they have been specially manufactured for permanency. On the whole, the lists of permanent pigments drawn up by the various artists' colourmen will be found fairly trustworthy for practical purposes. It is also necessary not to use two pigments that act chemically upon each other, and it must also be remembered that the transparent blues and greens, when mixed with oil and laid pure on the canvas, unless in very thin glazings, tend to degrade, owing to the yellowing of the oil.

The oil painter to-day is faced with similar problems to those of the oil painter of the fifteenth century, namely, that a medium which yellows with age, and that certain pigments, such as flake white, grow more translucent with time, and therefore the permanent brilliancy of an oil painting, after having selected his pigments as advised by the chemist, depends on the technical skill of the artist.

Some English Cathedrals and Stone Decay.

The Cathedrals of Durham, Lincoln, Ely, and Norwich have been visited, and in addition the condition of the stone at Hampton Court and the Houses of Parliament has been re-examined.

The ruins of Elgin Cathedral were first discussed. In order to understand what is happening here and elsewhere it is necessary to classify the stones used for building into three main groups: the lime-stones, the sand-stones in which the quartz particles are united by calcite, and the sand-stones in which the particles are united by silica. This classification will be regarded by petrologists as wanting in detail and being somewhat diagrammatic in character, but it will be the most convenient for the present purpose, which is an inquiry into the injury caused to modern buildings by the presence of sulphur dioxide in the air produced by the burning of coal.

The ordinary causes of stone decay do not require special mention here as they are well known to architects and builders. The new and the main cause of the rapid decay taking place in modern buildings is the attack on the calcium carbonate of the lime-stone and of the calcite forming the binding material in sand-stones by sulphur dioxide in the presence of air and moisture, forming calcium sulphate. Calcium sulphate is slightly soluble in water, and therefore is being slowly dissolved in the rain and removed, but this is not the most serious cause of damage. Cases of rapid decay are found to be associated with the crystallisation of calcium sulphate inside the stone and the consequent breaking up of the stone.

In some cases where siliceous sand-stones have been used, the source of lime must be the mortar, the rain dissolving and washing the lime into the stone. Analyses at remote places like Ely and Tintern Abbey have shown that the destruction by the action of sulphur dioxide is not confined to the towns, but is spread over the remote country districts.

Probably the best thing that can be done is to treat such stone surfaces with a binding material depositing silica cement, and periodically to wash down the building with water during the summer with the view of removing the excess of sulphate of lime, and thus diminish the danger of crystallisation. While it is not possible in the state of our present knowledge to say whether such washing can be safely applied to every variety of lime-stone, experiments in this direction are well worthy of the serious consideration of architects.

British Institute of Radiology.

IN the issue of the *British Medical Journal* for November 8 an account is given of the new British Institute of Radiology. This is situated in Welbeck Street, W.1, the house of the old Russian Embassy. The Embassy consisted of a lofty, roomy house, and this has been altered and adapted to meet the needs of the new Institute.

The main objects of this—the first of its kind in Great Britain—are set out in full in the article in question, and are the outcome of joint deliberations between representatives of the British Association for the Advancement of Radiology and Physiotherapy (B.A.R.P.), the Royal Society of Medicine, and the Röntgen Society. Primarily, it may be said that the object of this Institute is to promote the advancement of radiology and physiotherapy on scientific lines under the direct control of the medical profession, protecting in every possible way the interests of those engaged in these subjects. Further, it is hoped to provide facilities for the delivery of lectures, the holding of classes and examinations, the establishment of scholarships, and the granting of prizes, diplomas, etc., in radiology and electrology. Arrangements are well in hand for the formation of a library and radiographic museum. These two features have been much helped by gifts of books from Lady Mackenzie Davidson and the presentation of radiographs from many interested in the Institute.

Membership of the Institute is, however, by no means restricted to the medical profession, for not only are physicists, engineers, and manufacturers of electrical apparatus eligible in this respect, but representatives of them have also from the first been invited to join in the discussions precedent to the formation of the Institute.

The present needs of the Institute are largely financial. It was helped at its formation by the action of the trustees of the Mackenzie Davidson Fund in

handing over a sum which had been publicly subscribed to perpetuate the name of Mackenzie Davidson. Even so, however, additional expenses have been incurred, and an appeal is now made for a sum of 6000*l.*, which will pay off arrears and allow for future developments.

Reference to this Institute would be incomplete without mentioning the name of Sir Archibald Reid. It was largely due to his untiring efforts that the Institute took shape when it did, and his memory is being perpetuated by the formation of a reference collection of radiographs, both normal and pathological.

The acceptance of the presidency of the Institute by Sir Humphry Rolleston, Bart., president of the Royal College of Physicians, is proof, if any were needed, of the interest of the medical profession in this venture and of their concern for its development. It is also one more instance of the many services which have been rendered by Sir Humphry Rolleston in the cause of medical radiology. S. RUSS.

University and Educational Intelligence.

CAMBRIDGE.—Mr. H. E. Tunnicliffe and Mr. N. J. T. M. Needham have been elected fellows of Gonville and Caius College. The John Bernard Seely Prize in aeronautics has been awarded to W. A. Johnson, Peterhouse, for an essay on "Dynamical Similarity and Scale Effects."

Dr. D. H. S. Cranage has been appointed secretary of the Board of Extra-mural Studies, and the Rev. J. W. Hunkin has been appointed secretary of the General Board of Studies.

The scheme for the creation of a class of extraordinary or visiting professors, to which reference has already been made in these columns, was rejected by one vote.

EDINBURGH.—The Prince of Wales has consented to open the new Chemistry Department of the University on December 3.

GLASGOW.—Mr. J. J. Lister has presented to the University the microscope used throughout his life by his uncle, Lord Lister, together with a number of auxiliary appliances and mounted preparations. The valuable and interesting relics will be placed, with the microscope of William Hunter, in the Hunterian Museum.

The microscope of Bentham, the botanist, has been presented to the Botany Department of the University by Mr. James Whitton, late superintendent of the city parks and gardens.

The Bellahouston Trustees have, in honour of the Kelvin Centenary, made a grant of 2000*l.* to the University for the purchase of modern electrical apparatus for the use of the Natural Philosophy Department, now under Prof. H. A. Wilson.

LEEDS.—We have already referred in these columns to the "Smithells Fund" which was being raised to commemorate the services of Prof. A. Smithells to the University. The Fund has now reached a total of nearly 2500*l.*, of which about one half represents contributions from the gas industry. A portrait of Prof. Smithells has been painted by Mr. Fiddes Watt for presentation to the University. The presentation ceremony will take place on November 25. The balance of the Fund will provide a scholarship, of approximately 100*l.* per annum, which is to be established in the University in the name and with the advice of Prof. Smithells.

THE Harper Adams Agricultural College, Newport, Salop, is requiring an analyst and demonstrator in its chemical department with, if possible, experience in agricultural-chemical analysis. Particulars are obtainable from the principal of the college.

THE following election results complete the list of Parliamentary representatives for the Universities of Great Britain and Northern Ireland:—OXFORD: Lord Hugh Cecil (U.) and Sir Charles Oman (U.); SCOTTISH UNIVERSITIES: Sir Henry Craik (U.), Mr. D. M. Cowan (L.), and Sir George Berry (U.).

MR. H. T. CRANFIELD, who has held the post of senior lecturer in agricultural chemistry and head of the Chemical Department at the Midland Agricultural and Dairy College for several years, has been appointed adviser in agricultural chemistry, under the Ministry of Agriculture scheme, for the Midland Counties served by that College.

THE council of the British Electrical and Allied Manufacturers' Association (Inc.) have recently granted the following scholarships and renewals of scholarship tenable for one year, each of the value of 100*l.*, together with the payment of college fees:—*In Electrical Engineering:* Mr. J. T. Birtwell, at the College of Technology, Manchester; Mr. G. E. G. Foden, at the College of Technology, Manchester; Mr. P. J. Maggs, at the City and Guilds (Eng.) College, South Kensington; Mr. H. G. Richards, at the University of Birmingham; Mr. R. Robinson, at the University of Durham. *In Mechanical Engineering:* Mr. J. C. Burke, at the College of Technology, Manchester. *Renewals of Scholarship:* Mr. A. B. Everest, at the University of Birmingham, for metallurgical research in relation to electrical engineering; Mr. I. H. Hedley, at the University of Durham, for electrical engineering; Mr. G. S. C. Lucas, at the City and Guilds (Eng.) College, South Kensington, for electrical engineering, to enable him to carry forward his studies in alternator design; Mr. B. S. Pelton, at the University of London, for mechanical engineering (steam turbines).

THE appointments to Ramsay Memorial Fellowships in chemical science for this session, British, Dominion, and foreign, are practically completed. At the present time sixteen fellowships are being held in the universities and colleges of the British Isles. The list of awards for the present session, together with the university or college which has been selected by the fellow for his research, is as follows: *British*—Dr. Samuel Coffey (University College, London), Dr. A. F. Titley (University of Oxford), Mr. Sidney W. Saunders (University College, London). *Glasgow*—Mr. T. S. Stevens (University of Oxford), Dr. Alex. Robertson (since resigned on appointment to an International Fellowship in New York). *Canadian*—Dr. Edward H. Boomer (University of Cambridge). *Danish*—Mr. Kai J. Pedersen (University of Bristol). *Dutch*—Dr. J. Kalff (University of Manchester). *French*—Dr. H. Weiss (Royal Institution, London). *Greek*—Dr. Nicolas Oeconomopoulos (University College, London). *Italian*—Dr. Antonio Nasini (University of Cambridge). *Japanese*—Dr. Kameyama (University College, London). *Norwegian*—Mr. Leif Lindemann (provisional). *Spanish*—Dr. Miguel Crespi (University College, London). *Swiss*—Dr. Walter Feitknecht (Royal School of Mines, London). The total value of the annual amount of the fellowships that is awarded is approximately 4800*l.*, of which approximately 3300*l.* is provided by grants from Dominion and foreign sources.

Early Science at the Royal Society.

November 23, 1664. Monsieur Le Febure presented his printed discourse, both in French and English, upon the preparation of Sir Walter Raleigh's cordial. He likewise read a Latin letter sent him from Paris, and signed for attestation by some of the principal physicians and chirurgeons of that city, concerning the art practised by one Monsieur Bienaise, of healing tendons and nerves transversely cut, so as to restore the patient to the full use of his limbs. He was desired to leave the letter with the society, which he promised to do, after he had shewn to some of the college of physicians.

November 25, 1663. The president acquainted the society, that he had received a letter sent to a minister in England from a suffragan bishop in Iceland; which letter being produced, the secretary was ordered to peruse it, and give an account of it to the society at their next meeting; against which time the amanuensis was ordered to make a copy of the inquiries formerly drawn up by Mr. Hooke and sent to Iceland, in order that they might be considered of, and fitted by the president to be sent and recommended to the said bishop, as a person conceived to be capable and curious enough to return a proper answer to them.

November 26, 1662. The lord viscount Brouncker acquainted the Society with the approach of St. Andrew's day; and that by reason of the necessity of making some alterations in their charter, there could not be conveniently made an election of new council this year: but it was offered to the Society, whether they would propose some other persons to be presented to the King, and, according to his majesty's pleasure, to be put into the council of the altered patent, instead of some of those, who were in the first. It was put to the question, whether any alteration should be made in the council, or not? and it was carried in the negative.—Dr. Wilkins showed his way-wiser, and the effects thereof upon a coach; and was desired to leave his first engine of this kind with the society.

November 28, 1666. Mr. Henry Howard [afterwards Duke of Norfolk] was elected and admitted, who also received the public thanks of the Society for his respects to them.—Dr. Wallis gave the society some account of what he had lately observed in Kent about tides, viz., that, according to his hypothesis, the tides had been very high about Romney-marsh, three days after the new moon; which though the seamen there ascribed to the high winds, as not thinking of any other cause, yet he thought it might be imputed to the cause assigned in his theory; especially if upon continued observations for several years together it should happen in the same manner.

1667. Mr. Coga, the first person in England, on whom the experiment of transfusion was made by order of the Society, and by the management of Dr. Lower and Dr. King, presented himself before the Society, and produced a Latin paper of his own, giving an account of what he had observed in himself since he underwent the said experiment. It was ordered likewise that Mr. Coga being willing to have the experiment repeated on him, it should be tried again accordingly, when the physicians of the Society should judge it seasonable. [Oldenburg in a letter to Boyle, takes notice that the experiment was performed at Arundel-house, in the presence of many spectators, including Mr. Henry Howard and both his sons. The morning after the lord viscount Brouncker and Mr. Oldenburg went to see Mr. Coga pretty early.]

Societies and Academies.

LONDON.

Royal Society, November 13.—Sir Arthur **Schuster**: On the total reflection of light. The light which enters the optically rarer medium at or beyond the critical angle is an effect of diffraction originating near the boundary of the refracting surface. It derives its energy from the incident beam and must diminish the intensity of the reflected light. Thus there can be no total reflection in the strict sense of the word. The ratio of the energy dissipated by diffraction to the total energy of the incident light is inversely proportional to the length of the refracting surface, and therefore tends towards zero as the size of the refracting surface increases. At the critical angle the light dissipated by diffraction amounts to about one per cent. of the incident light, when the length of the refracting surface is 5 cm. The numerical value is subject to correction depending on the approximate nature of the investigation.—N. K. **Adam** and J. W. W. **Dyer**: The molecular structure of thin films. Pt. VI. Five long-chain alcohols have been examined. The area of cross-section of the chain in the alcohols is the same as in the acids, within 2½ per cent., and the CH_2OH group occupies 21·6 sq. A.U. of area. The acetates of these alcohols pack with the heads occupying 23 sq. A.U., and form expanded films of the same kind as other esters. The methyl ethers of the alcohols do not form stable films. Highly unsaturated acids, with three and five double bonds in the chains, behave much like oleic acid, which only has one double bond. Arachidic acid and its derivatives behave normally. Substituted acetamides show a solid film with chains close-packed at low temperatures, and this melts at a definite temperature, raised by compression, to a liquid film of area 24·2 sq. A.U. This melting seems to be due to the molecules acquiring sufficient kinetic energy other than translational to break up the solid structure. Hydrocarbon chains more than 27 carbons long tend to mask the typical phenomena in condensed films. Pentærythritol tetrapalmitate, which has four chains attached to a common centre through polar groups, and should normally have these four chains directed to the corners of a tetrahedron, orients all the chains vertically in the surface. These are not quite close-packed until a compression of about 20 dynes per centimetre is applied.—T. **Alty**: The cataphoresis of gas bubbles in water. The velocity of a gas bubble in water is independent of the gas used. It is proportional to the applied field throughout the whole range of diameters, the maximum velocity being $4{\cdot}1 \times 10^{-4}$ cm./sec./volt/cm. at a diameter of about 0·1 mm. The highest velocity is only attained in water of specific conductivity $8{\cdot}5 \times 10^{-6}$ ohms^{-1}. In water of specific conductivity $1{\cdot}8 \times 10^{-6}$ ohms^{-1}, the charge on the bubble is very small, and is occasionally reversed during the course of an experiment. Two bubbles appear to repel each other.—D. R. **Hartree**: Some relations between the optical spectra of different atoms of the same electron structure. I.—Lithium-like and sodium-like atoms. Relations between values of corresponding terms of the spectra of different atoms of the same electron structure are worked out for the Bohr atom model with a central field. The relations are different according as the series electron does or does not penetrate into the core. The theoretical relations agree fairly closely with such experimental data as are available.—P. A. M. **Dirac**: The conditions for statistical equilibrium between atoms, electrons and radiation. The principle that every process which

occurs in an assembly in thermodynamic equilibrium is exactly balanced by the reverse process occurring to the same extent is applied to the general case of n-body encounters, both radiative and non-radiative processes being considered. Van 't Hoff's isochore is of universal validity, even for radiative processes and with relativity mechanics. From Planck's law of radiation it is deduced that every process by which radiation is emitted is stimulated by external radiation of the same frequency, the ratio of stimulated to spontaneous emission being independent of the nature of the process, and inversely proportional to the cube of the frequency.—Ida **Doubleday**: Boundary lubrication—further consideration of the influence of the composition of the solid face.—Christina C. **Miller**: The Stokes-Einstein law for diffusion in solution. Dilute solutions of iodine in a large number of solvents of different viscosity were used. According to the Einstein-Stokes expression, which is based on the assumption of large particles moving amongst relatively small molecules, the product [diffusion-coefficient × velocity] should be constant for all solvents. The product in the case of organic solvents actually varied between 850 and 1544; for aqueous solutions of alkali halide of different concentrations the variation was between 826 and 1216. According to Sutherland, on the opposite assumption that small dissolved molecules move amongst relatively large molecules, the value of the product in the extreme case should be 1·5 times as great as the value given by the Einstein-Stokes expression. If acetylene tetrabromide be excepted, the ratio for any two products actually falls between 1 and 1·5.—Helen S. **French** and T. M. **Lowry**: Studies of co-ordination, Pt. I. Absorption spectra and co-ordination of some cupric compounds. The absorption-spectra of the cupric compounds, both organic and inorganic, are dominated by (i.) a red or infra-red band, which is characteristic of the cupric atom, and (ii.) an ultra-violet band or general absorption, which depends mainly on the anion or organic radical. The colour of the cupric compounds depends on the character of the narrow region of transmission between these two absorptions.—L. F. **Bates**: On the range of α-particles in rare gases. A scintillation method was used, and the value found for helium, after repeated purification of the gas used, is very different from that found by previous observers, due probably to the big effect of small quantities of impurities in reducing the range. Henderson's theory of the loss of energy of an α-ray in passing through matter, whilst accounting for approximately the same fractional loss of energy in all the rare gases, does not account for the whole loss. There is a rough linear relation between the logarithms of the observed stopping powers and the logarithms of the atomic weights of the rare gases, but it does not take the simple form given by Bragg and Kleeman. —D. H. **Black**: The β-ray spectrum of mesothorium 2. Thirty-one lines were detected and their energies calculated. The majority of these lines are considered to be due to the conversion of γ-rays in the absorption levels of the atom itself. In all, eight γ-rays have been classified, and it has been possible to account for seven of these quite satisfactorily by the system of transitions between levels in the nucleus. —J. Keith **Roberts**: The thermal expansion of crystals of metallic bismuth. The thermal expansion of crystals of metallic bismuth parallel and perpendicular to the vertical axis, by comparison with that of crystalline quartz, are practically constant from ordinary temperatures up to 240° C. Bismuth melts at about 270° C. The constant expansion coefficients over this range are:—Perpendicular to the axis, $12{\cdot}0 \times 10^{-6}$; parallel to the axis, $16{\cdot}2 \times 10^{-6}$; mean, $13{\cdot}4 \times 10^{-6}$. The bending over of the length-temperature curve as the melting-point is approached indicates dissociation of the atoms in the solid.—R. **Stoneley**: Elastic waves at the surface of separation of two solids. A wave, analogous to the Rayleigh wave, exists at the plane surface of separation of two elastic solids, which extend otherwise to infinity, if the velocities of distortional waves in the two media are nearly equal. A transverse wave of the type that Prof. Love has shown to exist in certain circumstances in a surface layer cannot exist at this surface of separation. A wave of this type may exist in a stratum of uniform thickness bounded by media extending to infinity if the stratum is sufficiently thick or the wave-length sufficiently small. Nodal planes may also exist. The geophysical bearing of these results is that some of the energy of deep-seated earthquakes may be "trapped" at surfaces of discontinuity, and eventually be dissipated in solid friction without appreciably affecting seismographs. —J. H. **Jones** and J. C. **Boyce**: The constants of the Rydberg-Ritz equation. The type of atomic field necessary to give observed terms in hydrogen-like spectra must be due to a virtual attracting charge which is additional to the net charge of the atomic kernel. The additional field, strong near the kernel, but rapidly diminishing at greater distances, resembles that of an electric doublet. The doublet seems to be induced in the kernel by the field of the valence electron itself, in its interaction with the screening electrons. This can be pictured as the charge induced on a conducting sphere, and for such a model a Ritz spectral formula may be derived. One of the correcting terms of the Ritz formula has been obtained for a number of spectra of the sodium type, and the values are of the same order of magnitude as those calculated from known spectral data.

Physical Society, October 24.—Mr. F. E. Smith in the chair.—D. **Gunnaiya** and G. **Subrahmaniam**: Underblown pipes. The phenomena of underblown pipes have been studied in the case of four wooden pipes ranging over an octave. They present many features of remarkable interest, and a new theory is proposed.—W. **Mandell** and J. **West**: On the temperature gradient in gases at various pressures. Sets of curves indicating these gradients at various pressures have been obtained; they show the existence in contact with the vessel walls—at low pressures—of very large "temperature jumps." The general character of the results may be explained on the assumption of the presence at the walls, of a gas film possessing certain properties due to the attracting forces existing amongst wall molecules and gas molecules. Several thermocouples of differing thicknesses—and therefore differing curvature—were employed under identical conditions. They showed systematic differences which may also be attributed to the presence round the various thermocouples of gas films the thickness and character of which vary with the thickness of the couple.—J. F. S. **Ross**: Vectorial dimensions: The paper directs attention to the deficiency of the present dimensional notation [M] [L] [T], and in particular to the anomalies (*a*) that it makes the dimensions of work and torque the same, and (*b*) that it allows the dimensions of angular velocity and acceleration to appear as functions of time alone. These defects are due to the neglect of the vectorial character of length, and it is accordingly proposed that the present notation be modified by using the symbols $[L_x]$, $[L_y]$, and $[L_z]$, where different directions are involved. The proposal by Bartorelli to treat angle as a fourth independent fundamental quantity is open to serious criticism.

Mineralogical Society, November 4.—Dr. H. H. Thomas and afterwards Prof. W. W. Watts in the chair.—M. S. **Krishnan**: Note on cordierite in a cordierite-gneiss from Madura District, Madras, India. Optically positive cordierite occurs in an Archæan gneiss produced by the metamorphism of biotite-gneiss by an intrusive tongue of charnockite. The associated rocks are crystalline limestones (with lime-silicate minerals), and gneisses containing felspars, garnet, sillimanite, biotite, and titanoferrite. Cordierite from two other localities in Peninsular India (Vizagapatam and Travancore) is also known to be optically positive. This positive character is suggested to be due to the isomorphous replacement of MgO by FeO, as in the rhombic pyroxenes, olivines, etc.—A. **Brammall**: Lime as a constituent of certain important rock-forming minerals: its behaviour relative to that of other bases of RO type. A review of the facts governing the extent to which RO-bases replace each other in rock-forming minerals, special reference being made to the antipathetic relationship between lime and magnesia as constituents of the same simple molecule.—L. J. **Spencer**: (1) An inclusion of magnetite in diamond. A minute black fragment (about 1 mg.) taken from a cavity in a diamond from Bultfontein mine, Kimberley, was definitely identified as magnetite. Black inclusions and spots are of common occurrence in diamond, but usually they are non-magnetic and therefore not magnetite. (2) Biographical notices of mineralogists recently deceased (second series). Notices of fifty-five English and foreign mineralogists. The average age of 303 lives (since 1876) is 64 years, and a curve shows a highest point at 74 years. The greatest age was attained by F. E. Neumann (1798–1895), the German crystallographer.—A. **Russell**: A notice of the occurrence of native arsenic in Cornwall (with analysis by H. F. Harwood); of bismuthinite at Shap, Westmorland; and of smaltite and niccolite at the Coniston Mine, Lancashire.

MANCHESTER.

Literary and Philosophical Society, November 4.—H. B. **Dixon** and W. F. **Higgins**: On the phosphorescent flame of carbon di-sulphide. In determining the ignition-point of mixtures of carbon disulphide vapour with other gases, *e.g.* hydrogen, nitrogen, carbon dioxide, methane, it was found that a mixture of 80 per cent. methane with 20 per cent. carbon disulphide immediately inflamed when brought into oxygen in a concentric-tube apparatus at a temperature of 191° C., but did not inflame in air until both gas and air were heated to above 410° and had been in contact 10 seconds. The mixture of methane and carbon disulphide was observed to give a phosphorescent glow when it met the air at temperatures between 200° and 400°, and by regulating the gas supply a steady flame could be maintained. This flame can be studied more easily in a glass tube, or by throwing a steady air current by means of a glass cone on to the gas jet. The phosphorescent flame is due to the partial burning of the carbon disulphide, to carbon mono-sulphide, and sulphur dioxide. The methane is not attacked. The flame does not come down to the jet: it lights some inches above it. When certain gases, such as ethylene, acetylene, coal-gas, nitrogen peroxide, mix with the gas and air near the orifice of the jet, the phosphorescent flame is immediately extinguished—but these "poison" gases have no effect when brought into the flame itself. The phosphorescent flame is accompanied by particles of the red-brown polymer of CS and appears to be due to the partial burning of CS_2 molecules condensed on these solid particles. The "poison" appears to prevent this condensation.

PARIS.

Academy of Sciences, October 27.—M. Guillaume Bigourdan in the chair.—The president announced the death of Louis Emile Bertin, the oldest member of the section of geography and navigation, past-president of the Academy.—Paul **Appell**: The nature of the movement of a fluid celestial body round its centre of gravity.—G. **Friedel**: An experiment demonstrating the symmetry between the increase and decrease of crystals.—Édouard **Imbeaux**: The great artesian basins of the United States.—Paul **Montel**: The exceptional involutions of the algebroid functions.—Maurice **Fréchet**: An intrinsic parametric representation of the most general continuous curve.—S. **Stoïlow**: The continued transformations of a variable.—Alfred **Rosenblatt**: Varieties of three dimensions the tangent spaces of which satisfy certain differential equations.—R. **Jacques**: Networks such that the congruences described by the tangents and the congruences derived by the Laplace method belong alternately to linear complexes.—Jean **Thibaud**: The absorption and diffusion of γ-rays of very great energy in the light elements.—A. **Dauvillier**: A method of distinguishing natural pearls from culture pearls. The means hitherto available for distinguishing between the pearls produced artificially in the oyster by the Japanese method and natural pearls, necessitate the destruction of the pearl. It is shown that the photographs of the Laue figures produced by X-rays are different for the two classes of pearl, and this examination does not require the mutilation of the pearl.—Jules **Stoklasa** and Jos. **Penkava**: The radioactivity of the eruptive gases of Vesuvius and of solfataras and their influence on the development of bacteria and the higher plants. Details of measurements of the electrical conductivity of the air near two craters of Vesuvius, at different altitudes on the Eiffel Tower in Paris, and at the potash mines at Mulhouse.—L. J. **Simon**: The neutralisation of chloric acid by the alkalis, followed by means of viscosimetry. The minimum viscosity corresponds to equimolecular proportions of alkali and acid.—E. **Audibert**: A necessary condition for safe mining in an inflammable atmosphere. Doubt is thrown on the efficacity of inert rock dust for preventing the propagation of explosion in mines.—A. **Lassieur**: The electrolytic separation of copper, antimony, lead and tin.—A. **Damiens**: The suboxide of tellurium. The experiments described do not confirm the production of tellurium suboxide under the conditions given by Divers and Shimozé. The reaction indicated by them is incomplete when working with pure tellurium, and the body described as the suboxide TeO is only a mixture of tellurium and the dioxide TeO_2.—J. A. **Muller** and Mlle. E. **Peytral**: The sudden pyrogenic decomposition of methyl formate and the principle of minimum molecular deformation. Methyl formate, passed rapidly through a hot tube at 1000° C., splits up into two molecules of formaldehyde; secondary decomposition of the aldehyde gives rise to carbon monoxide and hydrogen.—J. **Barthoux**: Contact metamorphism in the Djebilet ad Rehamna, Morocco.—Sabba **Stefanescu**: The apparent anomalies of the molars of elephants and the number of plates of their crowns.—A. **Maige**: The regeneration of the amylogen excitability of the plasts during hydrolysis.—L. **Leger**: The specific value of the three kinds of European lamprey and the young stages of *Petromyzon fluviatilis*. From a study of the young post-larval stages, the author concludes that the three kinds of European

lamprey, known under the names of *Petromyzon marinus*, *P. fluviatilis*, and *P. planeri*, must be considered as distinct species, since their differential characters, clearly marked in the adult, are already shown from the metamorphosis which follows their long larval life in fresh water.—M. **Parat** and J. **Painlevé**: The internal reticular apparatus of Golgi, Holmgren trophosponge and vacuome. The "reticular apparatus" of Golgi or the "trophosponge" of Holmgren results from the precipitation of metallic silver or osmium in the interior, at the periphery, or in the interspaces of the protoplasmic vacuoles. The author concludes that there is no cellular "apparatus."—A. **Bonnet**: The digestive and absorbing apparatus of some Echinideæ.—Eugène **Aubel** and René **Wurmser**: The utilisation of the energy liberated by oxidations.

BRUSSELS.

Royal Academy of Belgium, May 6.—M. Max Lohest in the chair.—Report on the work of the Committee on "Biographie Nationale" during the year 1923-1924.

June 7.—M. Max Lohest in the chair.—The P. J. and Ed. van Beneden Prize (2nd period, 1921-1923) is awarded to M. Daleg for his researches on the physiology of the egg during maturation: the decennial prize for applied mathematics (period 1913-1922) to M. De Donder for his works on the Einstein gravific and his treatises on thermodynamics and physical chemistry.

August 2.—M. Max Lohest in the chair.—The Edouard Mailly Prize is awarded to the Antwerp Astronomical Society.—Th. De **Donder**: The Weyl-Eddington-Einstein gravific.—Victor van **Straelen**: An amphipod from the oil-bearing strata of Pechelbronn (Alsace). Details of a new species to which the name of *Gammarus alsaticus* is given.—M. **Alliaume**: The best approximation in the determination of the instantaneous terrestrial pole and an attempt at the systemisation of researches on the deviation from the vertical.—M. **Alliaume**: The generalisation of Poisson's theorem relating to the probability of an event the cause of which has undergone an unknown modification.—R. **Lucion** and A. **Brichaux**: Experiments undertaken by Ernest Solvay, from 1877 to 1881, on the fundamental unity of matter and energy.—E. **Ectors**: Contribution to the study of the reaction of organo-magnesium compounds on the nitriles. Benzonitrile. An account of experiments made to elucidate the mechanism of the reaction between benzonitrile and benzylmagnesium chloride.—Suzanne **Leclercq**: New observations on the anatomical structure of some fossil plants of the Belgian coal measures. Two new species are described, *Botryopteris Fraiponti* and *Sphenophyllum Gilkinetti*.—A. **Merten**: The calculation of barrage walls.—Victor van **Straelen**: The first remains of fossil Phacochoerus collected in the Belgian Congo.—J. de **Smedt**: The diffraction of the X-rays by polymerised liquids.

DUBLIN.

Royal Dublin Society, October 28.—Prof. E. A. Werner in the chair.—H. H. **Jeffcott**: The determination of the most economic size of pipe line for water-power installations. In choosing the size of pipe lines and tunnels leading from a reservoir to the turbines in a hydroelectric installation, the criterion of greatest economy is that the sum of all the charges in connexion with the pipe lines (including the value of the power lost in the pipes), when reckoned over a long period of years, shall be a minimum. Reducing the diameter of such pipe line lessens cost, but increases the loss of power due to frictional resistance, and, owing to loss of head at peak loads, it is necessary either to increase the size of the turbines, or to install additional turbine and generator sets to supply the deficiency at large discharge. From these considerations formulæ are obtained for the theoretically best sizes. As practical considerations require the thickness of wall of the pipe to be not less than a specified quantity, the low-pressure portion of the pipe line is of constant size. Thereafter the diameter diminishes, and the thickness of wall increases gradually as the pipe line descends towards the power-house. For the tunnel portion of the system the diameter is constant under the conditions hypothesised. As the output of the power-station varies considerably from time to time, the total frictional loss of energy in the pipe line in a year is proportional to the mean cube of the several discharge rates during equal periods in that year.—W. R. G. **Atkins** and G. T. **Harris**: Seasonal changes in the water and heleoplankton of freshwater ponds. The plankton of two ponds was found to be very different, so the water was analysed and the plankton estimated at intervals for about two years. A new record was obtained for *Elakatothrix gelatinosa*. The electrical conductivity of the water was low when the P_H value was high; the seasonal changes differed in the two ponds. In spring the developing plankton used up all the phosphate, lack of which appeared to limit the increase in growth.—K. C. **Bailey**: The synthesis of urea from carbon dioxide and ammonia under atmospheric pressure. Urea can be synthesised from carbon dioxide and ammonia at atmospheric pressure by passing the mixed gases through the annular space between a quartz tube heated to a temperature higher than 500° C. and an inner water-cooled glass tube. It is advantageous to use the gases in the ratio of two volumes of ammonia to eight of carbon dioxide. The yield of urea increases with temperature to at least 700°.

Royal Irish Academy, November 10.—Prof. Sydney Young, president, in the chair.—K. C. **Bailey**: The reaction between ferric chloride and potassium thiocyanate. The reaction between ferric chloride and potassium thiocyanate in various proportions has been reinvestigated, and an explanation is offered of the seeming anomalies in the extraction of ferric thiocyanate by ether or amyl alcohol. No evidence has been found of the existence in the reaction mixture of a dithiocyanate.—K. C. **Bailey** and J. D. **Kidd**: Freezing-points of solutions containing ferric chloride and potassium thiocyanate. Freezing-point curves of solutions containing ferric chloride and potassium thiocyanate in varying proportions have been constructed, but no definite evidence was obtained of the formation of double compounds.

Diary of Societies.

MONDAY, NOVEMBER 24.

CAMBRIDGE PHILOSOPHICAL SOCIETY (in Cavendish Laboratory), at 4.30.—C. T. R. Wilson: Acceleration of β-Particles in Strong Electric Fields such as those of Thunderclouds.—Dr. G. F. C. Searle: The Determination of the Frequency of an Alternating Current Supply by the Vibrations of Rods.—Dr. F. W. Aston: Photographic Plates for the Detection of Mass Rays.—E. B. Moullin: The Current induced in a Wireless Telegraph Receiving Antenna.—R. R. S. Cox: Note on the Chemical Constant of Chlorine.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—Prof. T. J. Jehu and R. M. Craig: Geology of the Outer Hebrides, Part 2. South Uist and Eriskay.—J. A. Eldridge: Note on Professor Whittaker's Atomic Model.—W. Saddler: The Irreducible System of Concomitants of Two Double Binary (2,1) Forms.—A. C. Aitken: A Series Formula for the Roots of Algebraic and Transcendental Equations.—Prof. J. Tait and Dr. W. F. Emmons: Experiments and Observations on Crustacea. Part VI. The Mechanism of Massive Movement of the Operculum of *Balanus nubilis*.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—N. A. Allen and others: Discussion on The Electrostatic Wattmeter used for measuring Dielectric Losses in Cables.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle-on-Tyne), at 7.15.

ROYAL SOCIETY OF ARTS, at 8.—Dr. L. C. Martin: Modern Colour Problems (1) (Cantor Lectures).

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—G. J. Goldie and Prof. Collingwood: Note on Protagulin in Hæmorrhage after Extraction.

MEDICAL SOCIETY OF LONDON, at 8.30.—Sir Anthony Bowlby, Bart., and others: Discussion on The Treatment of Senile Gangrene.

TUESDAY, NOVEMBER 25.

ROYAL DUBLIN SOCIETY (at Royal College of Surgeons, Dublin), at 4.15.—Miss S. D. King: Oogenesis in *Lithobius forficatus*.—Rev. H. C. Browne: The Influence of the FitzGerald Contraction on Space Measurements and Clock Times.

ROYAL SOCIETY OF ARTS (Dominions and Colonies Section), at 4.30.—Lord Stevenson: British Empire Exhibition.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—D. L. Thornton: The Rôle of Technical Training in Marine Engineering.

INSTITUTION OF AUTOMOBILE ENGINEERS (Informal Meeting) (at 83 Pall Mall), at 7.—Demonstration and Discussion on Car-cleaning Devices.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—G. Rogers: Automatic and Semi-automatic Rectifier Sub-stations.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—F. R. Newens: With Camera and Colour Plate.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Graduates Section) (at Broadgate Café, Coventry), at 7.15.—W. W. Small: Body Building.

ROYAL ANTHROPOLOGICAL INSTITUTE (at Royal Society), at 8.30.—P. Rêné Verneau: La Race de Néanderthal et la Race de Grimaldi: Le rôle dans l'humanité (Huxley Memorial Lecture).

WEDNESDAY, NOVEMBER 26.

INSTITUTION OF AUTOMOBILE ENGINEERS (North of England Section) at 244 Deansgate, Manchester), at 6.30.—Mr. Martin: Automobile Coa building.

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (at 39 Elmbu Crescent, Glasgow), at 7.—Ex-Bailie W. B. Smith: The Future Prosp of a Clean Atmosphere.

ROYAL MICROSCOPICAL SOCIETY (Industrial Applications Section) (joi with Institution of Structural Engineers), at 7.30.—J. E. Barna The Elementary Principles of Microscopical Illumination (2). S Luminous Objects.—H. J. Deane: The Application of Microscopy Cement Research.

ROYAL SOCIETY OF ARTS, at 8.—C. F. Elwell: Talking Motion Picture

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at Royal Society Medicine), at 8.30.—Dr. D. E. Core: The Clinical Value of Cert Emotions.

THURSDAY, NOVEMBER 27.

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), 4.30.—Dr. W. Edgecombe: The Principles of Spa Treatment in Gr Britain (Presidential Address).

ROYAL AERONAUTICAL SOCIETY, at 5.30.—Dr. G. C. Simpson: Thund storms.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. J. Findlay: Education and Rhythm.

INSTITUTION OF AUTOMOBILE ENGINEERS (Luton Graduates Meeting) Luton), at 7.30.—G. D. Ricketts: Production.

SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section, jointly wi Society of Dyers and Colourists) (at University College, Nottingham) G. H. Ellis: Acetate Silk.

FRIDAY, NOVEMBER 28.

PHYSICAL SOCIETY OF LONDON (jointly with Royal Meteorological Socie (at Imperial College of Science), at 5.—Discussion on The Ionisati of the Atmosphere, and its Influence on the Propagation of Wirel Signals.—Dr. W. H. Eccles: Opening Address.—Dr. C. Chree: Atm spheric Ionisation and its Variations.—Prof. E. V. Appleton: Expe mental Observation of the Strength of Wireless Signals as affected the Path of the Signals, Time of Day, and Season of Year.—R. Watson Watt: Atmospherics.—C. T. R. Wilson: The Electric Fie of a Thundercloud and some of its Effects.—Prof. S. Chapman: T Evidence of Terrestrial Magnetism for the Existence of Highly Ionis Layers in the Upper Atmosphere.

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), 5.30.—Discussion and Demonstration on The After-treatment of Medic Diseases of Joints.

JUNIOR INSTITUTION OF ENGINEERS, at 6.30.—Exhibition of late Scientific Instruments and Appliances for the use of Engineers.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Capt. C. W. Knight: Bird Life from an Observation Post.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDE (at Literary and Philosophical Society, Newcastle-on-Tyne), at 7.30. J. Tutin: The Prediction of Critical Speeds in Ship Resistance.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDE (Middlesbrough Branch) (at Cleveland Scientific and Technical Instit tion, Middlesbrough), at 7.30.—H. G. Clement: Ships' Life-Savi Appliances.

INSTITUTION OF MECHANICAL ENGINEERS (Sheffield Section) (at Sheffield —Prof. F. C. Lea: Effect of Repetition Stresses on Steels.

SATURDAY, NOVEMBER 29.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDE (Graduate Section, jointly with North of England Institute of Minir and Mining Engineers) (at Neville Hall, Newcastle-on-Tyne), at 3.

ROYAL IRISH ACADEMY, at 4.15.

PUBLIC LECTURES.

SATURDAY, NOVEMBER 22.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—F. Balfour-Browne: Soci Life amongst Insects. II. Butterflies and Moths.

TUESDAY, NOVEMBER 25.

WESTFIELD COLLEGE, HAMPSTEAD, at 5.15.—Rev. Dr. W. B. Selbie Psychology and Religion.

KING'S COLLEGE, at 5.30.—Miss Hilda D. Oakeley: Bosanquet's Theor of the State and Society.

WEDNESDAY, NOVEMBER 26.

INSTITUTE OF HYGIENE, at 3.30.—Dr. H. G. Anderson: The Prevention o Physical Deformities.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Prof. W. Cullis: The Practic of Health.

MEDICAL SOCIETY OF LONDON, at 5.15.—Dr. W. M. Feldman: Ante-Nata Child Physiology and Hygiene (Chadwick Lecture).

UNIVERSITY COLLEGE, at 5.30.—A. Esdaile: The British Museu Library. II. The Collections.

THURSDAY, NOVEMBER 27.

BEDFORD COLLEGE FOR WOMEN, at 5.15.—Prof. Neilson Jones: Dua Personality in Plants.

KING'S COLLEGE, at 5.30.—O. V. Salomón: The Modern Civilisation o Peru.

UNIVERSITY COLLEGE, at 5.30.—Prof. E. G. Gardner: The Personality o Mazzini.

FRIDAY, NOVEMBER 28.

KING'S COLLEGE, at 5.30.—Prof. E. W. MacBride: Scientific Method.

SATURDAY, NOVEMBER 29.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—S. H. Warren: Prehistori Man and the "Land of Lyonesse."

NATURE

SATURDAY, NOVEMBER 29, 1924.

The Boxer Indemnity and Chinese Education.

IF it were not for the remarkable powers of recuperation which China has shown on more than one occasion after an apparently crushing disaster, present conditions in that country would appear to afford anything but an opportune moment for discussion of the possibilities of reform and regeneration. An enormous number of her population, estimated at thirty millions, has been rendered destitute by floods, and the country is in the throes of civil war between rival provincial governors. Yet the situation is not entirely without hope. China, for better or for worse, has adopted the form of Western institutions of government. Whatever may be the outcome of the present struggle, which represents on one side an attempt to secure unity with strong central control by force, the future of the country will depend upon how far the Chinese are enabled to assimilate the spirit of Western culture, without which superficial measures of reform may well be a delusion and a disaster. A wise use of the Boxer indemnity, which is to be remitted from the year 1922, would play a paramount part in shaping the course of events. The size, the vastness of the resources, and the immense numbers of the population of China, make the question of her future development of vital and world-wide interest. It is unnecessary to emphasise here the importance of China as a centre of production in relation to world supply, both now and still more in the future. The fact alone that two hundred thousand foreigners are resident in the country, for the most part interested in some form of industry or commerce, makes good government and the stability of the country a matter of immediate concern to the nations to which they belong, while it is no longer possible that a state of unrest in almost any country, however remote, can for any length of time fail to affect other parts of the world.

Without going into detail, it may be useful to recapitulate briefly the present position of the Boxer indemnity so far as Great Britain is concerned. In 1922 it was decided by the Government then in power to remit the balance of the indemnity due from China to Great Britain on account of the Boxer Rising in 1900. The indemnity was payable over a term of years which had been extended to 1945. The payments affected thus cover a period of twenty-three years, the amount payable being 400,000*l.* per annum, representing a capital sum of approximately 11,000,000*l.* The remission, however, was not absolute: the amount due is still to be collected from various sources of Chinese revenue; but instead of being paid into the Sinking Fund, it is to be devoted to objects beneficial to both

countries. A Bill to give effect to this decision was introduced into Parliament in May of this year, but has still to be passed by the legislature.

It is scarcely necessary to enter into the reasons which led to this course of action on the part of the British Government; nor indeed have they ever been fully stated. One consideration which no doubt carried great weight was the fact that of the powers interested, two—the United States and Japan—had already remitted their indemnities on conditions. Great Britain could not have stood aside without damage to her prestige. France also, without remitting her payments, has devoted them to liquidating the affairs of a French bank in China of which the depositors were mainly Chinese. The claims of Germany, the largest participant, were cancelled during the War. Payments to Russia ceased after the collapse of that country, but, by arrangement between China and the Soviet Government, the whole of the Russian indemnity, arrears and future payments alike, is to be devoted to "promotion of education among the Chinese people."

Misappropriation of the funds made available by the cancellation of the obligation to Germany, has served as a warning to those powers which were prepared for remission. They desired to act for the benefit of China; but it was clear that in the disturbed condition of the country which has prevailed since the reform movement of 1911, a strong hand was needed to secure that the people as a whole would profit by the advantages which should accrue from a judicious expenditure of the amount thus made available.

In the Bill introduced into Parliament it was stated, following the announcement on remission made in December 1922, that the amounts receivable from the indemnity fund were to be expended upon objects beneficial to both countries. Various suggestions have been put forward to give precision to this vague phrase. Deputations have urged that the money should be expended on public works under British supervision. Another suggestion was that a Science Museum should be instituted at Peking. In favour of the latter proposal there is little to be said. Even if the country were sufficiently advanced to reap the full benefit of such an institution, difficulties of communication and transport would militate against the free and extended use which alone would justify such a disposal of the funds. The benefit would be confined to Peking. For the former, the proposal to devote the money to public works, there is more to be said, but here again the amount is so small relatively to the size of the country, that in the end it could do little more than benefit one or two more or less restricted areas. Nor is appropriation for this purpose by any means such an urgent need as it has been attempted to make out.

If a broad view of the situation be taken, there ca be no two opinions that both the needs of China an the wishes of the Chinese themselves point unmistak ably in one direction, and that is education. This vie has, at any rate, commended itself to the two powe which have already remitted the indemnity. In eac case the funds are to be made available for educatio It was at the suggestion of the Chinese themselves tha the Russian indemnity has been devoted to this purpos Among British residents in China, those who are mos competent to speak with authority, namely, the repre sentatives of the British Chambers of Commerce, hav been most emphatic in urging the claims of educatio Further, they have insisted that the situation calls fo education on British lines. Thereby they hope tha something of the British public school spirit may b introduced into Chinese education.

While the Chinese are endowed with many admirabl qualities, in which those who know them best can se much that is closely akin to ourselves, they have man weaknesses which are no doubt due to the isolation i which their civilisation developed. Among them mus be reckoned a too restricted view of their obligations an duties as citizens, arising from their intense preoccupa tion with the claims of the family group. To this mus be attributed many of the defects of their governmen and public life, while, coupled with their distrust o foreigners, it has been responsible for their failur in their international relations both in peace an in war. Without any desire to offend, it may b said that they lack the training in public morality which education on British lines might be expected to develop. By long tradition the Chinese have a devotion to education which amounts almost t veneration; but that they themselves recognise the defects of their system is shown by the efforts a reformation which they have made since 1911. Chinese education is now under the control of a Minister o Education, and with Peking as administrative centre there is a national system which includes primary and secondary schools, colleges and several universities. China thus possesses the skeleton of a system; but it must be confessed that it is nothing more than a skeleton, and perhaps, to continue the metaphor, not very successfully articulated. In addition, account must be taken of a number of educational institutions of all grades partly or wholly under foreign management, to a great extent the result of missionary enterprise.

The problem how best to utilise the resources which would be made available by using the Boxer Indemnity is in reality twofold. Although it has been possible to touch upon conditions in China only in the most cursory manner, probably enough has been said to show that a prolonged training is necessary before the

country can take the place in the comity of nations to which its importance, particularly in commerce, and its ancient civilisation might lay claim. Nor has anything been said of the danger to the rest of the world which lurks in neglect of this aspect of the question. It follows, however, that on one hand means should be found to give every assistance to the efforts of the Chinese themselves to reform and regenerate their educational system: on the other, it is urgently necessary to secure that such efforts at reform should be inspired by ideals of public and international morality in consonance, but not necessarily identical, with those of Western nations—a not insoluble problem, as is shown by the example of Japan.

It is evident that two considerations must be kept to the fore. In the first place, the sum available is small in proportion to the needs of so vast and so thickly populated a country, and as the funds come to an end in twenty-three years, permanence in result can only be secured by the co-operation of the Chinese themselves. Secondly, however, much as it may be desired to inculcate the spirit of a Western ideal, the education should be thoroughly national in character. The denationalised Chinese student is providing an element of danger in the present political situation which, with extended facilities for education on the lines of which he is the product, might become exceedingly grave. It is therefore necessary that most careful consideration should be given to any scheme which invites or requires Chinese co-operation such as was suggested by the representatives of the British Chambers of Commerce in conference at Shanghai in February 1923, who while urging emphatically that the funds from the Boxer Indemnity should be applied in the direction of education on British lines, regarded it as essential that in distribution there should be "adequate representation of China's opinion," or such a scheme as that outlined recently in these columns (August 30, p. 301), and also by Dr. R. P. Scott in the November issue of the *Empire Review* (see NATURE, November 15, p. 726). These schemes take into account the broad issues we have stated, namely, that, so far as possible, China as a whole should benefit in the exercise of British goodwill, that the fundamental considerations for success are real co-operation and sound finance; also, that higher education is the only field on which effective co-operation is feasible.

In conclusion, there are two points to which it is hoped attention would be given in working out details. One is that, in addition to scholarships for Chinese students tenable in Europe or America, there should be an exchange of lecturers for periods of at least a year; and secondly, that ample provision should be made for research in the geography, social history, and economics of China.

The Glands that regulate Sex.

The Internal Secretions of the Sex Glands: the Problem of the "Puberty Gland." By Prof. Alexander Lipschütz. With a preface by F. H. A. Marshall. Pp. xviii + 513. (Cambridge: W. Heffer and Sons, Ltd.; London: Simpkin, Marshall and Co., Ltd.; Baltimore, Md.: Williams and Wilkins Co., 1924.) 21*s.* net.

THE field of sexual physiology has been so active since "Die Pubertätsdrüse und ihre Wirkungen" was published in 1917, that it has been found necessary to rewrite the book and to give it a new title. Comparison of old and new provides a clear indication of the advances that have been made and of the modifications in opinion—including the author's own—that they have caused. The book is well planned and well written (in English): the illustrations are bountiful and excellent. There are a few of the inevitable typographical errors, and occasionally the author might perhaps have been happier in the choice of his word. But these are merely finicky fault-findings. This book can be strongly recommended to all those for whom the sections in Marshall's "Physiology of Reproduction" dealing with this subject are not sufficiently complete or recent, for in his treatment of the problems of sexual differentiation the author writes as a master.

The general theme of the book is that "in the ontogenetic development of the soma there is in the beginning an asexual stage, the subsequent differentiation of which is caused by the formative action of the sexual glands" (Steinach 1912, Lipschütz 1917). It is submitted that the soma is indifferent in the sense that either male or female sex-characters can develop, according to the kind of the sex-hormone, male or female, produced by the gonads. It can be said that the author has no difficulty in showing that in the mammal the sex-glands elaborate hormones which are able to modify the organism in a sex-specific way.

The book is of particular interest for the reason that it demonstrates in the clearest possible way the interrelationship of genetics and physiology. The problems of sex-determination have been appropriated by the geneticist, those of sex-differentiation by the physiologist, and as yet there is no link between the two. The author falters when brought face to face with the sex-chromosome sex-determining mechanism and finds it difficult to reconcile his theory of sexual differentiation with the established facts of sex-determination. The point of view of the physiologist is expressed in the statement (p. 104) that "*ceteris paribus*, femaleness depends on the ovary, maleness upon the testicle." The geneticist agrees that in the mammal, if an individual is to assume the sexual characterisation appropriate to the male, there must

be present in its body a functioning testicle, that *phenotypic* maleness (*i.e.* maleness as expressed in characterisation) depends on the testis, phenotypic femaleness on the ovary; but from the point of view of the geneticist, an individual develops a testis because it is a *genotypic* male, an ovary because it is a genotypic female.

Maleness and femaleness are characters in the Mendelian sense and are based upon hereditary sex-determining factors brought into the zygote by the conjugating gametes. In the genotype (the factorial constitution) of each zygote there are male-determining and female-determining factors, and these, it must be assumed, elaborate specific sex-differentiating substances. In the genetically determined male it is the rule for the balance between male- and female-determining factors to be such that the male-differentiating substances are efficiently in excess at that time during the development of the individual when the differentiation of the gonads occurs, and under these conditions the gonads become testes. In the determined female, on the other hand, the female-differentiating reactions are in excess at that time, and so the gonads become ovaries.

In order to bring the geneticist and the physiologist into agreement it is only necessary to extend the conception of asexuality, so ably developed in this book, so as to include the gonads. In the development of the gonads there is in the beginning an asexual (indifferent) stage, the subsequent differentiation of which is caused by the formative action of the sex-differentiating substances elaborated by the sex-determining factors. The embryonic gonad, according to the kind of internal environment (established by the sex-determining mechanism) in which it finds itself, can develop into either ovarian or testicular tissue.

The case of the free-martin (p. 389) has not been completely explained by the physiologist. The free-martin is a genotypic female whose sex-differentiation has been directed by the sex-hormone of its male co-twin, and whose sexual organisation is consequently abnormal. Difficulty is made of the fact that whereas the tissues of the genotypic male respond completely to the stimulus of the internal secretion of the testes, those of the genotypic female fail to do so. It is known that genotypic male and female tissues are to be distinguished by differences in their chromosome content and therefore, it may be assumed, in their physiological constitution, and it is reasonable to expect that, though both kinds may be capable of responding to one and the same stimulus, they will respond differentially. In the case of the free-martin, the male co-twin develops testes because he is a genotypic male and the testes elaborate the male sex-hormone. This, passing into the body of the genotypic female before her gonads have differentiated into ovaries, swings her sexual differentiation in the male direction. The swing is not complete becau the sex-hormone of the testis is not equivalent physi logically to the sex-differentiating substances elaborat by the male sex-determining factors and because t tissues of the genotypic female are constitutionall different from those of the genotypic male.

In dealing with the question of the physiologic action of the gonad in the fowl, the author, naturall enough, draws largely upon the work of Pézard and h collaborators, and with their opinions the geneticis frequently finds himself in disagreement. On p. 46 for example, the fact that Brown Leghorn cock an Silver Dorking hen threw daughters with the plumag characters of the Brown Leghorn, whereas Dorkin cock and Leghorn hen gave daughters with the plumag characters of the Dorking, is interpreted as a case of sex *limited* inheritance and the different plumage characte of the two kinds of daughters as an indication o a racial specificity in sex-hormone activity on th part of two different kinds of ovarian tissue. Pro Lipschütz suggests that, if this theory is correct, ovario tomy of the two kinds of daughters should give th same result, namely, a plumage presenting a mixture o characters of Leghorn and Dorking, whereas, if such castration experiment were to result in the plumage o a Leghorn poularde in one case and of a Dorkin poularde in the other, it would be necessary t reject the theory. We assure him, however, that thi very experiment has been undertaken, with the resul that Leghorn and Dorking characterisations wer obtained. There is not the slightest reason to cal upon any product of the ovary in order to interpre these straightforward results of a mating involvin sex-*linked* inheritance. It is enough to postulate tha gold and silver are allelomorphic characters, that thei factors are resident in the X-chromosomes, and that the female is the heterogametic sex.

Minoura's work on the artificial free-martin in the chick, to which reference is made (p. 311), demands critical repetition before it can be accepted as evidence of sex-hormone action. Any one who is well acquainted with the marked variability in the differentiation of the gonads and associated ducts in the chick must consider that Minoura's results were possibly due to simple interference with the normal process of sexual differentiation leading to irregularity and retardation, being in no way indicative of a specific action on the part of the implanted ovarian and testicular tissues.

In breaking a lance with his authorities, we do not criticise the author of this book; we merely take advantage of the appearance of so good a book to record our regret that it is not always possible for the physiologist to be well versed in genetics, the geneticist in sexual physiology. F. A. E. CREW.

Collective and Individual Effort in Colloid Chemistry.

(1) *The Theory and Application of Colloidal Behavior: Contributed by the foremost Authorities in each division of the Subject.* Edited by Dr. Robert Herman Bogue. (International Chemical Series.) Vol. 1: *The Theory of Colloidal Behavior.* Pp. xi+444+xx. Vol. 2: *The Application of Colloidal Behavior.* Pp. vii+445-829+xx. (New York and London: McGraw-Hill Book Co., Inc., 1924.) 2 vols., 40*s.* net.

(2) *Kolloidchemie und Biologie. Zugleich dritte Auflage von Kapillarchemie und Physiologie.* Von Prof. Dr. Herbert Freundlich. Pp. 47. (Dresden und Leipzig: Theodor Steinkopff, 1924.) 0.50 dollar.

THE editor of a collective work has, no doubt, a difficult and delicate task, and one would scarcely desire him to simplify it by adopting for his own and his collaborators' guidance the cynical maxim: "It does not matter what we say, as long as we all say the same thing." At the same time, while the sentiment expressed in the sentence is reprehensible, the commendation of unanimity or consistency contained in the clause deserves serious consideration.

(1) Such unanimity on fundamentals is quite conspicuously lacking in "Colloidal Behavior," more especially in the first volume, which deals with theory. In the preface, the editor dates the rise of a rational colloid chemistry from the application, by the late Dr. J. Loeb, of physico-chemical principles, *i.e.* Donnan's membrane equilibrium, to the colloidal behaviour of proteins, and confidently suggests that an extension of this method will explain the behaviour of all types of colloids. In the first chapter, Mr. J. A. Wilson attempts to give support to this view, and to apply the theory of heterogeneous equilibria to gold sols, by treating them as systems of three phases: "The solid surface, the film of solution wetting the surface, and the great bulk of solution." Whether it is in accord with classical physical chemistry to treat two regions of a continuous mass of liquid as distinct phases may seem doubtful.

In spite of the fundamental importance thus claimed for Loeb's theories (which, by the way, have not been unreservedly accepted by any one entitled to speak with authority in Europe), the authors of the remaining chapters appear to have little use for them. Prof. E. F. Burton refers to them (adversely) in one sentence in "The Kinetics of Disperse Systems," while Prof. McBain, in the brief but convincing chapter on "The Study of Soap Solutions," succeeds in explaining the behaviour of these typical colloidal electrolytes without ever mentioning membrane equilibria.

Again, in Chap. iii., Dr. J. H. Northrop professes "little doubt" that Perrin's logarithmic formula accurately expresses the vertical distribution of colloid particles. In Chap. v., Prof. Burton suggests that it holds over a range of about 0·1 mm. only, and quotes Porter and Hedges, who gave the complete law in 1922. These are all disagreements on fundamentals—those on minor points are numerous but need not be quoted. The experienced reader who knows the difficulty of keeping abreast of the widely scattered literature, who is aware that even sound theories become periodically unfashionable while unsound ones may stimulate research, will take such discrepancies lightly, but their effect on the student must be unfortunate.

While making every allowance for the difficulties of an editor who can scarcely exercise a censorship of all contributions (some of which, unless American authors differ radically from European, probably arrive in time to be sent to the printers by special messenger), one can reasonably expect him to do two things, if he makes such claims as Dr. Bogue does in his preface. The first is that the contributions should cover the whole subject, and the second that they should be arranged on some definite principle. The work fails in both respects; indeed, the omissions are remarkable. This is the first text-book on colloid chemistry which has no chapters on the ultra-microscope and its use, on the optical properties of sols (not even the Tyndall phenomenon is mentioned), or on viscosity. Nor does the work give any information on experimental methods such as dialysis (apart from a special apparatus briefly described by Prof. Freundlich), ultra-filtration or cataphoresis, though the reader is certainly entitled to look for it in a book claiming to be an advanced work of reference.

As regards arrangement, it is difficult to understand how chapters on the colloidal behaviour of the body fluids, on catalysis and enzymes, have come to be included in the theory of colloidal behaviour. The study of simple protein sols has no doubt helped to elucidate the properties of the highly complex mixtures which occur in organisms, but surely the reverse cannot be postulated. In the same way, while catalytic activity may be a very important property of a few disperse systems, it is not characteristic of the majority, and the study of catalysis can bear but indirectly on the theory of colloidal behaviour. The place for these chapters is obviously the second volume.

Incomplete and unco-ordinated as the material is, the first of the two volumes still contains a great deal that will be of interest to readers sufficiently grounded in the subject to exercise discrimination. The chapter on "Surface Energy" is welcome as a summary of the modern views on this fundamental subject by one of their distinguished originators, Prof. Harkins. Prof. Michaelis's article on "Adsorption" not only shows

how these views may be applied, but also incidentally brings out the highly specific character of adsorption by charcoal, the material used most widely in theoretical investigations. Prof. H. B. Weiser's contribution on "Jellies and Gelatinous Precipitates," and Prof. McBain's on "The Study of Soap Solutions," are valuable summaries, while Prof. E. C. Bingham in "Viscous and Plastic Flow" finds a subject which has not yet received due attention in Great Britain.

The second volume, which deals with the applications of colloidal behaviour to mineral, vegetable, and animal products, contains a vast amount of material impossible to summarise. It has often struck the reviewer as curious that colloid chemists should be so anxious to justify their existence or, perhaps, to magnify their office, by insisting on the applications of the discipline; writers on, say, physical chemistry, do not find it necessary to devote an exact half of their space to "applications." One of the reasons for this attitude may possibly be that the rapid development of colloid chemistry has fallen into a period during which science and an obscure activity called "research" have received much patronising commendation, not as objects in themselves but as possible agencies in the production of wealth. It would be unfair to suggest that the applications described in the work under review, or indeed in others, are all technical and quoted for their material results; in many instances the only claim made is that colloid chemistry has provided a new method of attacking problems of a purely scientific character. But the wish to make such claims has rendered the term "application" very elastic; it may connote a mere restatement in colloidal terminology, or an actual imitation or model of natural processes carried out in colloid material such as used by Nature. Every variety between these extremes is represented in the second volume.

(2) Prof. Freundlich's brief "Kolloidchemie und Biologie," the reprint of an address, also treats of one application of colloid chemistry. That it should here be placed beside the first collective work on the subject is (so far as the reviewer is concerned) an accident which has its piquant side, as the name Freundlich immediately calls up recollections of the greatest individual achievement in the literature of colloids, his "Kapillarchemie." Dr. Bogue must have overlooked it when he wrote in his preface, ". . . no attempt has heretofore been made to gather together material for an advanced text or reference work. . . ."

In the pamphlet under review, the author begins by reminding the reader that all organisms are built up from colloidal material, and then proceeds to show how the increasing knowledge of the colloidal state may be utilised by the biologist and physiologist. The parts played in living tissues by adsorption, electric charges at boundaries, swelling of elastic gels, are not only discussed in general, but each is also illustrated by concrete examples. Many of these are of great interest: thus the elucidation of hydrocyanic acid poisoning by a model in which the active factor—structural elements containing iron—is the same as in tissue. The striking fact that organic structures may, in the course of life, be completely transformed chemically while the appearance revealed by the ultra-microscope or even by X-ray analysis remains unaltered is shown to have its inorganic parallel in bodies capable of reacting rapidly throughout their mass, like the natural and artificial zeoliths, etc.

The brief but highly stimulating survey will be read with profit both by biologists and colloid chemists. It may perhaps induce a few adventurous spirits among the latter to forsake the well-trodden path, to abandon gold sols for a season, and to try their hands at what is surely the most important and most fascinating "application" of colloid chemistry—the elucidation and imitation of the phenomena of life. E. HATSCHEK.

Eddington's Relativity.

The Mathematical Theory of Relativity. By Prof. A. S. Eddington. Second edition. Pp. ix+270. (Cambridge: At the University Press, 1924.) 20*s*. net.

THE second edition of Prof. Eddington's book is a reprint of the first edition with the addition of a number of supplementary notes and one or two corrections. Some of the notes are designed to remove misunderstandings such as are constantly met with in debates on the relativity theory. Others give alternative mathematical treatments of various points, as, for example, the establishment of the four mathematical identities which correspond to the condition of conservation or permanence of the material world.

The main new matter contained in the notes falls under two heads—gravitational waves and affine geometry. Note 7 gives a summary of new results in the study of gravitational waves, and shows that the absolute disturbance is propagated with the velocity of light. At first sight there are other waves of a semi- or completely longitudinal type which may travel with a different velocity, but, in the picturesque language which Prof. Eddington still maintains, "these are merely sinuosities of our co-ordinate system. They exist, not in the world, but in our mental attitude, and the only speed relevant to their propagation is the speed of thought." Note 8 is a very interesting discussion of the gravitation of waves set up by a spinning-rod. This had been previously discussed by Einstein. The author gives a new discussion which confirms

Einstein's calculation save for a factor 2. The effect of the waves is to produce a loss of energy at the rate $32k\mathrm{I}^2\omega^6/5$ where $k = 2{\cdot}7 \times 10^{-60}$ in C.G.S. units, I being the moment of inertia, and ω the angular velocity. This is an effect of the third order as compared with that expected by Laplace if gravitation travelled with the velocity of light.

Notes 13 and 14 refer to the recent developments of "affine" geometry, as distinct from metric geometry, and the consequent generalisations of the relativity theory. In the latter note an account is given of Einstein's recent work in this region (Berlin *Sitzungsberichte*, 1923). Einstein supposes that there exists an action which has a stationary value for all variations of the threefold set of coefficients which define the affine connexion, and shows how this may lead by a special choice of the action function to the same results as those obtained by Weyl and set out in § 90 of the text.

There is to be noticed a slight movement in the attitude of Prof. Eddington to the universe as a whole. In the concluding page of the first edition it is remarked that "it is perhaps likely that, after the relativity theory has cleared away to the utmost the superadded laws which arise solely in our mode of apprehension of the world about us, there will be left an external world developing under specialised laws of behaviour." In the concluding note in the present edition, physics is definitely divided into two parts, one of which we are competent to deal with by our methods of continuous analysis, and the other we are not competent to deal with. "We do not pretend to predict *a priori* how nature will behave, but it is not impossible to set limits to the behaviour of that part of nature with which we are competent to deal, if we know the limits of that competence." This careful and conservative statement will remove misunderstandings that hasty readers have formed from passages that might be quoted from the earlier text.

The bibliography has not been revised, but the most important papers that have appeared since the first publication are referred to in the notes. E. C.

British Desmidiaceæ.

A Monograph of the British Desmidiaceæ. By the late W. West and the late Prof. G. S. West. Vol. 5, by Dr. Nellie Carter. Pp. xxi + 300 + 39 plates. (London: Printed for the Ray Society, 1923.) 37*s.* 6*d.*

PROGRESS in the study of a difficult group such as the Desmidiaceæ depends to a very large extent on the publication from time to time of treatises giving an adequate representation of the momentary state of our knowledge. In the past, we have been indebted to de Brébisson, Lundell, Ralfs, and others for works that gave a great impetus to the study of this group. During the latter half of the nineteenth century, Ralf's "British Desmids" indeed formed the standard work of reference, but as the years advanced it became more and more out-of-date, and a new monograph was long overdue when the publication of Messrs. West's "British Desmidiaceæ" commenced in 1904. There can be no doubt that this work, which in thoroughness and general excellence far exceeded anything hitherto produced in this direction, marked a great step forward, epitomising as it did the extensive researches that had been carried out in the last quarter of the last century, and placing at the disposal of the scientific world the prolonged and unrivalled experience of two of the foremost algologists of the time. Its influence was almost immediately manifest and has become increasingly so with the publication of successive volumes.

That neither father nor son should have lived to see the completion of their great work is to be deplored from every point of view, but in the absence of their lifelong experience, the choice of Dr. N. Carter to undertake the compilation of the fifth and last volume was a particularly fortunate one. Trained by the younger West, and having worked on Desmids for several years in his laboratory, probably no better person could have been found. Her task was not an easy one, as, apart from numerous drawings, Prof. West left but very few notes on which the subject matter of the fifth volume could be based. The text is thus entirely Dr. Carter's own work, and she may be congratulated on having produced a volume that in no respect shows any falling off as compared with the earlier ones. In particular, the critical remarks that are appended to the descriptions of many of the species, are often very much to the point. A large number of the figures are reproductions of Prof. G. S. West's own drawings, but Dr. Carter has had to supplement these to a considerable extent. Her own excellent drawings in the majority of cases have been made from material identified by Prof. West, so that, so far as the figures on the plates are concerned, they practically represent the latter's opinion of the characters of the different species and varieties.

The greater part of the volume is taken up with the completion of the genus Staurastrum, the treatment of which was commenced in the fourth volume published eleven years ago. So much confusion reigns with reference to certain species of this genus (*e.g. S. paradoxum, S. gracile, S. simonyi*) that an authoritative account of some of them is particularly valuable. The last sixty pages are devoted to the colonial Desmids, which, in correspondence with the plan adopted in the first volume of the monograph, are treated together,

though probably more closely allied to certain of the non-colonial genera than to one another. The addenda include an amended diagnosis of the genus Roya and a redistribution of some of the species of Penium considered in Vol. 1, necessitated by Lütkemüller's work on the structure of the Desmid-membrane.

Those interested in the study of Desmids will particularly welcome the excellent index to the five volumes with which the present volume concludes, and which, in view of the involved synonymy, will greatly enhance the usefulness of the whole work.

F. E. FRITSCH.

Our Bookshelf.

Die natürlichen Pflanzenfamilien : nebst ihren Gattungen und wichtigeren Arten insbesondere den Nutzpflanzen. Begründet von A. Engler und K. Prantl. Zweite stark vermehrte und verbesserte Auflage herausgegeben von A. Engler. Band 10 : Musci (Laubmoose). Hälfte 1. Pp. iv+478. (Leipzig : Wilhelm Engelmann, 1924.) 30 gold marks.

ONLY those bryologists who worked in the 'seventies and 'eighties of the last century can realise the great difficulties which then existed in determining mosses which came from outside Europe. Karl Mueller's "Synopsis Muscorum Frondosorum," published in 1849, had become obsolete so far as its classification was concerned, and Jaeger's "Adumbratio," although putting forward a more natural classification, was entirely destitute of descriptions, which the student had to search for in a widely scattered literature. In 1898 this state of affairs was altered when the Musci were reached in Engler and Prantl's "Die natürlichen Pflanzenfamilien," the bulk of which, after special sections by K. Mueller, W. Ruhland, and C. Warnstorf, was from the pen of Dr. V. F. Brotherus, the publication of whose task was completed in 1909. The appearance of this last-named work rendered the task of bryologists easier, and caused such an accession to their ranks as to necessitate the production of a second edition, the first part of which has just been issued. It consists of a compact volume, which, like its predecessor, is copiously illustrated. A general account of the mosses (including Sphagnales and Andreæales) is given by W. Ruhland, and a special account of the Sphagnales by H. Paul. These occupy 142 pages. The remainder of the groups from Fissidentaceæ to Timmiaceæ has been worked out by the veteran Dr. V. F. Brotherus, who has the opportunity of examining types additional to those used in the preparation of the first edition.

The general plan of the work follows that of the earlier edition, and so renders its use easy to those already accustomed to this plan. Each group contains a key to the genera, and also in very many cases short diagnostic characters of the species, which greatly facilitate the identification of specimens. This is especially noteworthy in the case of the genus Bryum, which occupies 38 pages and contains a large proportion of the 800 species which are widely scattered over the earth and the determination of which has hitherto been a matter of great difficulty. References are made to publications up to 1922 in which new genera have be described. The book should prove a great stimulus the study of bryology, and we trust that ere long I Brotherus may be able to issue another instalment this work, which his long experience renders him competent to perform.

Permeability. By Prof. Walter Stiles. (*New Phy logist* Reprint, No. 13.) Pp. v+296. (Londo Wheldon and Wesley, Ltd., 1924.) 12*s.* 6*d.* net.

THERE is no doubt that Prof. Stiles has rendered a ve considerable service to physiologists by collecting ar arranging the large amount of material dealing wi the plasma membrane and permeability. As remarks, "Any one who takes the trouble to read t literature of the subject can scarcely fail to be impress by the isolation of thought of the majority of worke in this field." A monograph of this nature remov any excuse for such a state of affairs.

The work is of general interest to physiologist although it naturally refers chiefly to plant tissue The various chapters deal thoroughly with the exper mental evidence on which our knowledge of cell ar protoplasmic structure is based. The physical ar chemical behaviour of such systems is considered, ar finally the movement of water and other substanc into living plant cells. The last chapter is devoted the statement of the various theories of cell pe meability. A bald outline of these subjects cannot d justice to the thoroughness with which they are treate Two main features mark the treatment. The ant thesis between Haberlandt's view that "every prot plast is surrounded by a special dermal layer," an Fischer's statement, "There are no membranes abo cells," is considered in a critical presentation of th evidence on which these views must be based. Th second feature of Prof. Stiles's treatment may expressed in his own words, "While the propoundin of theories will continue to satisfy the minds of som yet it cannot be too strongly emphasised that what a wanted to lay the foundations of a proper understanc ing of the phenomena of permeability in plants a facts, and particularly quantitative data." This poin of view has been kept in mind throughout. The resul is a work of reference of great value, comprehensiv impartial, and, it may be added, non-committal. W may perhaps hope for a further contribution fro Prof. Stiles, in which he puts forward, however briefly his own views on these vital subjects.

The Leucocyte in Health and Disease : Being an Enquir into certain Phases of Leucocytic Activity. By C. J Bond. Pp. viii+84+24 plates. (London : H. K Lewis and Co., Ltd., 1924.) 12*s.* 6*d.* net.

THE sub-title of the volume under notice gives the mor accurate idea of its contents, for it deals almost entirel with the author's own researches during the last seve or eight years. Since Metchnikoff's views on phago cytosis aroused such wide interest, much study ha been devoted to the functions of the white bloo corpuscles and the part they play in resisting disease Most of such experiments are naturally done outsid the body, and it is difficult to know how far the observe facts are valid under more natural conditions.

The author is well aware of this difficulty and ha

made every effort to study the living cell under conditions as natural as possible. He describes certain appearances in the white cells during their activity and certain fine processes called dendrites, which function in much the same way as the blunter pseudopodia. These are illustrated by some excellent plates, but neither these nor his arguments convince one that the appearances are not artefacts, although his reasons are put forward very lucidly and temperately.

The most interesting and original part of the book is the attempt to probe into the chemical processes taking place in the leucocyte. Two substances are described. One of these occurs in the cell and stains readily with iodine, and may be of the nature of glycogen; the other readily diffuses from the cell and can be shown in the surrounding media, and it stains with benzidine and differently with iodine. It is not one of the ordinary oxidases and is probably aldehyde in nature. The author claims that if the leucocytes are incubated with glucose, more of the latter diffusible substance is produced in the presence of insulin.

The book cannot be recommended to the general reader, but will be of interest to the specialist. It seems to the reviewer that the experiments and the theoretical discussion would be better in the pages of a journal devoted to this subject than issued as a separate monograph.

Across the Great Craterland to the Congo: a Sequel to "The Wonderland of the Eastern Congo." Describing a Journey of Exploration and Research to the Land of the Giant Craters in Tanganyika Territory, and to the Forests, Lakes, and Volcanoes of the South-Eastern Congo; with some Account of the African Apes, and the Capture and Training of the African Elephant. By T. Alexander Barns. Pp. 276+64 plates+2 maps. (London: Ernest Benn, Ltd., 1923.) 25*s.* net.

CAPTAIN BARNS'S volume on his expedition in 1921–22 from Mombasa to the Congo at Stanleyville and thence to Capetown is a valuable contribution to the natural history of Central Africa. The author combines the qualities of a daring explorer and hunter, of a keen observer of man and Nature, and of a graphic and interesting narrator. The primary object of the expedition was the discovery of a large butterfly which has been seen on the Upper Congo, but has not yet been captured. On his way to the haunts of this elusive insect he explored a remarkable group of volcanic mountains and basins in northern Tanganyika Territory, and collected skins of some of the third species of gorilla, *G. berengei*, in the forests of Kivu. He also made a large collection of Lepidoptera, including many new and rare forms.

Capt. Barns has written an interesting account of the geography of the region north of Lake Tanganyika. The chapter on the gorillas contains valuable information as to their habits; another is devoted to the adventurous story of the domestication of the African elephant by the Belgians. The volume has an introduction by Prof. J. W. Gregory discussing the nature of the great volcanic basins explored by Capt. Barns. That of Ngorongoro is eleven miles in diameter. He concludes from the geological evidence available that they were not formed as craters, but as calderas or volcanic cauldrons. He defines the distinction between ordinary upbuilt craters, explosion craters and calderas or cauldrons, which have been formed by the collapse of the ground around a volcanic vent. The volume is illustrated by many beautiful photographs, especially of the scenery and big game.

An Introduction to Reflective Thinking. By Columbia Associates in Philosophy: Laurence Buermeyer, William Forbes Cooley, John J. Coss, Horace L. Friess, James Gutmann, Thomas Munro, Houston Peterson, John H. Randall, Jr., Herbert W. Schneider. Pp. vii+351. (London: Constable & Co., Ltd., n.d.) 10*s.* 6*d.* net.

THIS is one of those co-operative books which are becoming a feature of publishing enterprise. It has, however, some quite exceptional marks. The nine authors, members of the staff of the Department of Philosophy in Columbia University, are named on the title-page, but their individual contributions are not specified in the text. We are told in the preface that they sought advice and received aid from their colleagues in other departments. The book therefore has, and is intended to present to the student, a unity due to team work. It is offered as a first course in philosophy or as an introduction to science. Each chapter is divided into sections and followed by a list of questions and exercises and an extensive bibliography. The impression it leaves on us is that the interest of the matter is spoilt by the form, and the matter apart from the form is elementary to the point of insipidity.

Vibration in Engineering. By Julius Frith and Frederick Buckingham. (Reconstructive Technical Series.) Pp. xiv+123. (London: Macdonald and Evans, 1924.) 7*s.* 6*d.* net.

AN increasing degree of attention has been given recently in engineering colleges to the study of vibrations, and students will welcome the appearance of this volume in which has been collected a large amount of information hitherto scattered in various volumes dealing with physics and in technical journals. The matter is arranged in two parts, physical and mathematical, and vibrations commonly occurring in both mechanical and electrical engineering receive attention. For the most part the principles are stated clearly, but there are some loose statements which require amendment, *e.g.* on p. 11 we read, "The restoring force is now a turning moment, the force is measured in pounds weight as before, and its moment in feet."

Spinoza, Descartes and Maimonides. By Dr. Leon Roth. Pp. 148. (Oxford: At the Clarendon Press; London: Oxford University Press, 1924.) 7*s.* 6*d.* net.

DR. ROTH has produced a scholarly book. The author rejects the view that Spinoza is originally a follower of Descartes and that the purpose of his speculation is to develop the logical consistency of the Cartesian principles. He holds that he is mainly concerned to oppose and overthrow the theory of Descartes, and that he does so by recovering and reanimating the four-centuries-old doctrines of Maimonides in the "Guide to the Perplexed." The argument is not lightly to be set aside but it is scarcely likely to be convincing.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Rarity of the Inert Gases on the Earth.

IN NATURE of March 15 I published a diagram in which the abundance of the different species of atoms —up to mass number 79—was plotted on a log scale against their mass numbers. I have now extended this, with a small gap, up to mass number 142, and what was fairly obvious before has become, by the inclusion of the region containing xenon, a very striking feature. This is the abnormal scarcity of the inert gases.

I took for purposes of calculation an earth consisting of the atmosphere, the hydrosphere and a lithosphere of the average composition of the igneous rocks of mass equal to that of the whole globe. If we disregard the inert gases altogether, the points lie on at least the semblance of a curve. There are high peaks, O, Fe, Sr, Ba, abnormal depths, Sc, In, and a very marked depression in the region Ga, Ge, but nevertheless a curve is sufficiently well marked for any observer who had been given the mass numbers of the missing inert gases to allot them appropriate positions and so to calculate their most probable abundance. The point I wish to emphasise is that he would in every case state an abundance roughly 10^6 times greater than that obtained from actual atmospheric analysis.

This discrepancy will appear much the same if instead of mass number we plot by atomic number or by atomic weight, and it will not be affected seriously by supposing, as has been suggested, that the innermost quarter of the earth consists mainly of iron and nickel. It cannot very well be ignored, and three possible hypotheses suggest themselves, any or all of which might offer an explanation :—

(1) The fault lies in the method of calculating abundance; our sample is unfair, and if we could get a fair one, say from the interior of the earth, the discrepancy might vanish. This would require that the earth's atmosphere was entirely derived from a surface shell only a few metres thick—not a very hopeful view.

(2) The abnormal rarity of the inert gases is due to some nuclear property of instability held in common. We have good reason for supposing such a property common to the isotopes of a single element, but none whatever to ascribe it to a set of elements the mass numbers of which range from 4 to 136. It is true that these elements have a very definite property in common, chemical inertness, but this is, so far as we know, an extranuclear one. We are therefore driven to consider as more probable :—

(3) The earth has only one millionth part of its proper quota of inert gases. This very interesting conclusion is founded on very flimsy evidence, but it is not out of keeping with some such origin of the solar system as the planetesimal theory. In the hurly-burly of colliding bodies ranging in mass from atoms upwards, the atoms of the inert gases, unconstrained by irrevocable chemical combination and free to collide and rebound indefinitely, would inevitably gravitate towards the larger masses and forsake the less. On this view the earth's share of inert gases has been lost to the sun, though whether they still remain there unchanged is outside the question. Their abnormal rarity is at least a point of interest and invites comment from those interested in the evolution of our system and of the elements. F. W. ASTON.

The Cause of Cyclones.

IN the winter of 1922–23 there appeared in NATU some correspondence on "The Cause of An cyclones," and on that occasion I put forward cert views as to the mechanism by which the more ra increases of barometric pressure are brought abo in temperate latitudes (NATURE of March 31, 192 pp. 429-430). The present communication may regarded as a sequel in that its object is to descri a mechanism by means of which the more ra reductions of pressure can conceivably be produc The idea arises naturally from consideration of series of papers by Helmholz appearing in t *Sitzungs-berichte* of the Royal Prussian Academy Sciences in 1888 and 1889, dealing with the equilibriu of rotating rings of air at different temperatur and with the theory of winds and waves whe strata of different density lie contiguous with o another.

The conditions for equilibrium in cases where surface of discontinuity (of temperature and win exists in the atmosphere have since that time be dealt with by V. Bjerknes and others in som what more general fashion and need not be set o here.

Designating the warmer (southerly) mass by (and the colder (northerly) by (2), Helmholz calculat in terms of their velocities, temperatures and t latitude, the theoretical slope of the bounding surfa for a state of stable equilibrium. But, as he poin out, first small waves and then mixing of the tv media must soon occur over this boundary; H therefore calculates the slope for stability of t bounding surface between mass (2) and the mixtu and between the mixture and mass (1). He sho that these slopes are respectively more acute a less acute (relatively to the horizon) than the origin slope between mass (2) and mass (1). Hence, H says, results the important consequence that (tending towards the new requirements for equilibriu "all newly formed mixtures of strata that *were* equilibrium with each other must rise upwar between the two layers originally present, a proce that of course goes on more energetically when pr cipitations are formed in the ascending masse While the mixed strata are ascending, those parts the strata on the north and south that have hithe to rested quietly approach each other until the even come in contact, by which motion the diffe ence of their velocities must necessarily increas since the strata lying on the equatorial sid acquire greater moment of rotation (about th earth's axis) with smaller radius, while those o the polar side acquire feebler rotation with a large radius."

Now the importance of this reasoning, applied i the light of modern meteorological knowledge, appea to me enormous. Putting aside for the moment a theories as to the *origin* of cyclones, it appears to b pretty well established by the facts of observatio that the normal *structure* of an active and recentl formed depression at least approximates to that de scribed by Bjerknes.

Further, observation tends to confirm (1) that th principal reduction of pressure and the principal are of rainfall lie at any moment within the "old" col air in front of the Bjerknes Steering Line, (2) tha where the warm air extends right down to the groun no appreciable pressure-change is taking place, unles quite close to the Steering Line, (3) that where th "new" cold air is undercutting the warm air ther is rapidly rising pressure.

I have shown elsewhere that the rise of pressur in the new cold air and the comparative constancy

of pressure in the warm air and also the temperatures of these masses are consistent (dynamically) with their (supposed) northerly and southerly origins and with the processes to which they have been subjected in arriving on the field of operations; and further that the changes in the energy (potential, kinetic and internal) of the "new" cold current are sufficient to account for the work that is being done by it in displacing the warm air and filling up the rear of the depression. But I have never previously been able to see why in front of the depression the warm air should mount upon the old cold air, or why, if it did so, a fall of pressure should at the same time occur in the region below; though I have indeed been able to find evidence that a selected mass within the warm air was continually approaching a selected mass within the old cold air. Now if the Helmholz reasoning is sound we can make an important step forward. The mysterious "eviction of air," as Sir Napier Shaw has called it, is accomplished by the continual procession of the products of mixing of the warm and cold up a kind of giant escalator—with a moving roof as well as steps—hitherto described usually as the Steering Surface; and the process would go on so long as any warm sector remained.

At the moment I can see no fact of observation that is inconsistent with such a theory, and it further appears to lead to feasible energy equations for the front half of a cyclone.

In the problem dealt with by Helmholz the "eviction" and the subsequent "dumping" of the air do not seriously enter, and beyond the remarks quoted above, he devotes no consideration to either. As to the latter, Steering Surfaces appear to extend up to the level of the highest clouds and even into the stratosphere, and their inclination to the horizon appears to be of the order of 1 : 100. Hence the dumping need not take place within 1000 kilometres of the Steering Line and may be spread over an enormous area beyond that. The tracks of the most frequent North Atlantic depressions lie roughly parallel to the line of the (eastern) American and Greenland coasts, and in a belt about 1000 to 2000 kilometres distant from these coasts. The tracks of the North Pacific depressions are somewhat similarly situated with regard to Siberia. Of all places in the Northern Hemisphere the North America-Greenland area and Siberia would most welcome the dumping of surplus air and most of all at those seasons when depressions are most active. For these areas must be receiving air—probably at a high level—to compensate for the constant vertical contraction of the film of atmosphere there by cooling and for the recurrent discharges of cold air into the rear of passing depressions. In this way depressions might perhaps be regarded as the heat-receiving ends of thermo-syphonic arrangements, the corresponding radiating ends being areas like North America, Greenland, Siberia, or the Antarctic continent; both ends being necessary for the maintenance of the circulations. A secondary depression and its "dying" parent would perhaps bear a similar relation one to another. In all cases the principal supply of heat would be borne from equatorial regions by warm currents of high water vapour content. Given sufficiently complete synoptic weather charts of the northern hemisphere, to test the above theory by a combination of the facts of observation, hydrodynamics and thermodynamics would not, I think, be impossible, though the task would be one of some magnitude.

A. H. R. GOLDIE.

Organ-pipes of Unusual Shapes.

THROUGH the kindness of Prof. W. B. Morton I have been enabled to examine Robert Gerhardt's original inaugural-dissertation on the Rohrflöte, delivered at Halle in 1884. His equation for the case of a pipe with closed chimney is identical with that given by Principal Aldis (NATURE, Aug. 30) for the Bicylindron, and for the Rohrflöte proper with open chimney his equation is the same as mine. Gerhardt discovered a little of the history of this interesting pipe register. The Rohrflöte is apparently of considerable antiquity. Praetorius mentioned it in his "Syntagma Musicum" (1619), and the pipe was probably invented in the middle of the sixteenth century. Praetorius describes the position of the chimney as being wholly outside, half inside, or wholly inside, of which he recommends the last as offering the greatest protection to the chimney.

The theory of such a system was given by Bourget in 1873 in an explanation of the sound given when one cools a narrow glass tube, on one end of which a glass bulb has been blown. Without really extending the theory Gerhardt showed that by graphical means one can always calculate the possible frequencies of any such arrangement. He plots the curves:

$$y_1 = w \tan ml,$$
$$y_2 = -\tan mh$$

(using my nomenclature) and obtains the points of intersection:

$$ml = z\frac{\pi}{2} \pm \alpha,$$

where z is some whole number, α is found from the graphs and differs for every value of z, and the positive sign is taken for the Rohrflöte, the negative sign for the Bicylindron. Gerhardt therefore obtains for the fundamental frequency:

$$N = N_0\left(1 \pm \frac{2\alpha}{\pi}\right),$$

where N_0 is that of the pipe without a chimney when closed. In my previous letter (NATURE, Oct. 18) there is an error; $r/R = \tan \pi/n$ should read $\tan mh = \tan \pi/n$, where π/n is the least angle of which the tangent is $\tan mh$. Gerhardt's expression for the fundamental frequency gives the same values as mine although the form appears different. There is a mistake in my deduction of the overtones, and the given series is only true in some few particular cases. In general the interval between an overtone and its fundamental is $(zn+1)$, where z is an integer, but n is usually multivalued and the overtones quite inharmonic. It is obvious, however, that if the speaking length of the body is some simple multiple of that of the chimney, the points of intersection of the curves must repeat themselves after a definite interval, and hence in this case overtones occur which are simply related to one another. Gerhardt, however, considered the values of α in no way connected. His observations show excellent agreement with the values deduced from his graphs except when the ratio of the diameters approaches unity.

The whole subject of pipes possessing sudden changes of diameter has been attacked recently in a most comprehensive manner by P. Cermak of Giessen (*Ann. d. Phys.* 53, 1917). He first examined a closed pipe formed of two portions of equal lengths and of different diameters, and determined the change of pitch with change of the diameter ratio. The empirical law which satisfies these changes extremely well is

$$N = N_0(1 \pm \rho),$$

where N_0 is the fundamental frequency of a pipe of constant diameter and of the same total length, and

$$\rho = \left(1 - \frac{D_e}{D_w}\right)^{\frac{1}{4}},$$

where D_e and D_w are the diameters of the narrow and wide portions respectively. In the frequency formula the positive sign is taken if the narrow end is closed, the negative sign if one closes the wide end. The latter case is identical with that of the Bicylindron invented by Principal Aldis.

Cermak then proceeded to examine the change of pitch of pipes in which the two portions had a constant difference of diameter, when the junction was gradually moved from the narrow to the broad end, which was closed, and then for the opposite direction of movement with the narrow end closed, the total length being kept constant in both cases. He shows, as also did Principal Aldis, that the pitch in the first case falls to a minimum when the lengths of the two portions are equal, and then rises to its original value when the tube is once more uniform. Combining these results he obtains empirical formulæ giving the fundamental frequency of any closed pipe formed of any number of straight portions of any length and cross-section. His formulæ agree with his observations extremely well, but they are very complicated and most wearisome to handle.

Cermak obtains empirical formulæ for the case of the Rohrflöte, which also fit the results of experiment remarkably well, but he points out that Gerhardt's deductions differ from his observations most where his formulæ show best agreement, and vice versa.

From a brief examination of his curves, I should have expected that a formula built up from transcendental terms would be simpler, easier to handle, and give as good agreement, and, moreover, would give some insight into the physical meaning of the changes. Since Gerhardt's result admits only of graphical solution and conveys little sense of physical reality, one would welcome any equation, even though it were empirical, which might permit of the immediate solution of a problem, and if possible one which would admit of a simple physical interpretation. In the development of the compound resonator such formulæ would be invaluable.

Cermak's work is, moreover, extremely thorough. Of recent years many physicists have produced theories based on observations made with a single pipe, or at most three. Cermak used fifty-eight different pipes, and traced interesting analogies of the phenomena in the creation of longitudinal vibrations in rods of non-uniform section, in the transversal vibrations of strings having sudden changes of diameter, and in the resonance of electromagnetic oscillations in a parallel wire system in which the distance between the wires suddenly changes. To these I should like to add the effect of inserting a short length of wider tubing in a water pipe line in Constantinesco's wave-power transmission.

The Word "Scientist" or its Substitute.

THERE is a prejudice against this word. Some profess etymological scruples; they say it is an ugly hybrid with a Latin root and a Greek termination. But surely this is not a serious objection or the one which really prevents its use. For the accusation is not true. The termination *-ist* is French, not Greek; if "scientist" had come from the French it would have been as unexceptionable as "artist," which is an exact parallel; it did not come from French merely because French scientists, having appropriated *savant* (to which we have no close analogy), had no need of it. Even if the accusation were true, those who swallow "voltmeter" and "ionisation" would scarcely strain at such a very mild inelegance.

The real objection, I think, is different. "Scientist" was a doubtful neologism at a time when scientists were in trouble about their style. They were accused, with some truth, of being slovenly; and those who aimed at a higher standard were careful not to offer the slightest cause for offence. The word became a shibboleth. Matters have, however, now changed; we no longer need a shibboleth. Our sentences may not always be polished, but scientific journals contain no higher proportion of gross errors than the Proceedings of the Aristotelian Society or of the Classical Association. Moreover, the word has arrived; there is no chance of suppressing it entirely. Even if so far it were confined wholly to the illiterate—which it most certainly is not—we ought (as the authors of "The King's English" say) to "begin seriously to consider whether it has not been resisted as long as honour demands." Cumbrous circumlocutions, such as "man of science"—offensive to feminists and with an artificial air no artifice can conceal—are wretched substitutes. The idea is definite and important; the discovery that there is something common in the intellectual attitude of all the sciences and foreign to other branches of learning is one of the greatest advances made by the thought of the last century. For a new thing (to quote the same authors) we must have a new name.

Let me therefore plead with you, Sir, who have done so much to raise the standard of scientific literature, and with all others who have striven to show that scientific and linguistic precision are not incompatible, to give us a lead in this matter. If you will not have "scientist," at least provide us with some other single word. NORMAN R. CAMPBELL.

[Hitherto the word "scientist" has not been used in the columns of NATURE to designate a man of science or scientific worker, and Dr. Campbell now suggests that the time has come to reconsider the exclusion of the word. Our language has grown into what it is through process of change and development, and there is no permanent standard of purity for it; so that new words and phrases are continually being incorporated while others are becoming archaic. The only criterion as to what is permissible is that afforded by refined feeling or usage in the best literature of a particular epoch. We have, therefore, invited a number of authorities on good English, including distinguished men of science, to favour us with their opinions on the desirability, or otherwise, of adopting the word "scientist" to signify generically one who has at different periods been described as a natural philosopher, naturalist, or man of science, and we propose to publish any replies received of a critical or constructive kind. EDITOR, NATURE.]

Cell-wall Formation.

A CHARACTERISTIC difference between the processes of cell-wall formation in plants and animals has long been recognised. In the tissues of higher plants a new cell-wall is generally laid down on the nuclear spindle and then spreads peripherally until it cuts the cell into two. The cell-wall may thus be said to be endogenous in its origin. It is also generally believed that this plate on the spindle is first formed by the coalescence of a row of granules, afterwards

splitting into two layers which secrete the primary wall between them. In animal cells, on the other hand, the characteristic method of division is by constrictions or furrows beginning at the periphery and proceeding inwards. The same is true of many Thallophytes.

In recent years the observations of Farr on Nicotiana, Magnolia, Sisyrinchium and other forms, of Tahara on Chrysanthemum, and of the writer on Lactuca (Proc. Roy. Soc. B., vol. 91, p. 222, 1920), have shown that in pollen mother-cells, quadripartition usually occurs by furrowing. Recent critical observations of this process in the pollen mother-cells of Lathræa (in a paper now in the press in *La Cellule*) show that there are, however, essential differences between the process of furrowing as it occurs in pollen mother-cells and generally in Thallophytes, and the manner of furrowing in animal cells.

In Lathræa, a new wall is first formed inside the pollen mother-cell wall. At four equidistant points on this wall tetrahedral thickenings or deposits then appear, and from the apices of these thickenings four furrows grow in until they meet in the centre of the cell. But as the furrows advance, a delicate cell-wall, which is a continuation of the peripheral thickening and which has usually been missed, is deposited in each furrow.

In animal cells, Spek and others have shown that cleavage is accompanied by peripheral currents in the cytoplasm moving in the direction of the furrows. Early observations of J. Loeb and others, recently confirmed by Chambers (in "General Cytology," Ed. Cowdry, p. 296, 1924), show that in various animal eggs as the cleavage furrow is formed pigment granules accumulate in the wall. This process is to be contrasted with the secretion of a wall in the furrows of a dividing pollen mother-cell. Observations of Chambers on cleaving animal eggs also show that an appreciable time is necessary for the walls of the furrow to become non-coalescent when they come into contact. This hardening effect may perhaps be due to the accumulation of these granules in the walls.

It thus appears that there is an essential difference between the process of wall formation in pollen mother-cells and the cleavage of animal cells. In both cases a furrow is formed, but in the former a delicate cell-wall is secreted as the furrow advances, while in the latter there is no such secretion. We may thus say that quadripartition in pollen mother-cells combines the essential features of both methods of wall formation.

Nitrogen and Uranium.

YEARS ago, before the discovery of terrestrial helium, W. F. Hillebrand isolated this gas with nitrogen, in his work on rock analyses. Because a large amount of nitrogen was obtained he attributed all of the gaseous constituent to this source. Some of his analyses are described in the *American Journal of Science*, vol. 140, pp. 384-94, 1890, under the title, "On the Occurrence of Nitrogen in Uraninite and on the Composition of Uraninite in General," and more fully in Bulletin U.S. Geological Survey, No. 78, pp. 43-79, 1890. He concluded that "nitrogen exists in uraninite in quantities up to over 2·5 per cent., and seems generally to bear a relation to the amount of UO_2 present. This is the first discovery of nitrogen in the primitive crust of the earth." "The nitrogen is liberated from the mineral as nitrogen gas by the action of a non-oxidising inorganic acid and by fusion with an alkaline carbonate and probably also caustic alkalies in a current of CO_2." "In a Geissler tube under a pressure of 10 mm. and less, the gas afforded the fluted spectrum of nitrogen with great brilliancy." That uraninite is actually the source of the nitrogen is not open to doubt. Ramsay later confirmed Hillebrand's discovery. The chemical evidence suggests that the nitrogen was present in the mineral in the free state, as occluded gas. The question therefore arises as to how such a quantity of gas could accumulate. The unknown nature of its origin has been frequently mentioned by Dr. Hillebrand during the past thirty years.

Very likely the nitrogen is merely occluded in the uraninite in a manner similar to the occlusion of gases in charcoal. If so, this fact may prove important in problems of laboratory technique. From a more speculative point of view, however, in view of the fact that the atomic weight of uranium is almost exactly an integral multiple (17) of nitrogen, one is attracted to the possibility that the uranium nucleus may contain nitrogen nuclei. Further, the ejection of nitrogen of atomic number 7 from uranium should give the missing, and possibly unstable, element 85, with an atomic weight somewhat higher, to be sure, than should be expected. These latter questionable suggestions, wholly unsubstantiated by radioactive evidence, are offered merely to direct attention to the fact that the presence of nitrogen in uraninite is a problem of interest and importance.

Edible Earth from Travancore.

IN the Travancore Court of the British Empire Exhibition at Wembley several interesting products of this enterprising State were displayed. Among the medicinal products there were two substances named "Kalpal" and "Kalmadom." From a description drawn up by Dr. Kunjan Pillai, these are said to be deposits found in the clefts and hollows of high rocks "in the form of a brownish-white foam which on exposure becomes harder with time and has the consistence of lime-plaster." The decomposed rock is washed with water to remove foreign matter, as lichens, leaves, etc., and the sediment is made up into balls and dried in the sun. The lumps reduced to powder are said to be a valuable medicine for kidney complaints.

Dr. Pillai has kindly supplied me with samples of these materials, and they were at once recognised as forms of prepared edible earth used throughout India —"Kalpal" was in the form of white balls consisting of sand and clay, while "Kalmadom" was in rounded lumps with the colour and appearance of ochre. In a paper on "Earth-eating and the Earth-eating Habit in India," published in the Memoirs of the Asiatic Society of Bengal, vol. 1, No. 12, 1906, and noticed in NATURE of September 27, 1906, Dr. Mann and I have described about forty different kinds of edible earths, with the results of their chemical analyses, and a history of the habit. They were all siliceous earths, containing in a few cases a fair quantity of iron or lime. In tea estates the coolie women use the unctuous clay taken fresh from exposed deposits, but in the cities the clay is baked and sold in thin plates of various sizes. The earths we examined in connexion with this remarkable habit included the following varieties: Hydrated silica, cream-coloured clay, finely divided felspar, marl, yellow clay, brown clay, greyish calcareous clay, reddish micaceous loam, talc-schist, laterite, halloysite, blackish grey clay, brown earth from ant-hills, and infusorial earth.

Colour Nomenclature.

By Dr. L. C. MARTIN.

THE content and meaning associated with any word is always liable to vary with the mental outlook of an individual. Thus the word "distance" may convey to a psychologist the idea of a psychological experience developed by various means through the senses; to a physicist the same term conveys the idea of a magnitude to be expressed in centimetres or other arbitrary units. In practice, however, this causes very little inconvenience. The fundamental concepts are identical; it is the principle of measurement which varies.

Up to comparatively recent times the discussion of colour had connexion almost exclusively with the use of pigments, precious stones, and the like, in the decorative arts. Individual pigment names were satisfactory and not too numerous to remember, while the vast range of aniline dyes was unknown, but at the present time the use of colour names is in confusion. We recall the words of Locke: "Men take the words they find in use amongst their neighbours, and that they may not seem ignorant what they stand for, use them confidently without troubling their heads about a certain fixed meaning." We all suffer to some extent from this over-confidence. There is now a great need for some manner of measuring and specifying colour, which avoids the employment of these individual names.

The early work of thinkers and experimenters such as Newton, Young, Tobias Mayer, Johann Lambert, Runge, Grassman and Goethe cannot be reviewed here. We must begin with Helmholtz, who, inheriting the result of their labours, started with the basic idea of a three-dimensional continuum of colour sensations, the sensation being clearly differentiated from the stimulus. He was solely concerned with sensations when he described them ("Physiological Optics," 1856–66) as variable in terms of hue (Farbenton), saturation (Farben Sättigung), and brightness (Helligkeit). The subject of colour vision attracted great attention about this time, the work of Chevreul being translated (1854) into English by Charles Martel, who made in the introduction a plea for the more accurate standardisation of colour names by reference to the spectrum. Chevreul did not, however, trouble to distinguish between the sensation and the object seen; he describes colour variations by reference to the effects obtained by mixing white and black with various colours, but he uses the terms "tint" and "tone," which have not found acceptance for scientific work. Helmholtz had this in common in Chevreul, that he carefully described the physical conditions which would cause illustrative variations in the three sensation variables mentioned above.

Several other books, dealing with the subject mainly from the physical point of view, followed in the latter half of the nineteenth century. Benson (1871), having the benefit of Helmholtz's work, starts his account with the three fundamental sensations of the Young-Helmholtz theory of colour vision; this affords a radically different machinery with which to discuss colour sensation phenomena. It is still three-dimensional, but not so directly related to ordinary experience as the hue, saturation, and brightness. Rood ("Modern Chromatics" 1883) discusses "hue, luminosity, and purity," and describes experimental means of varying them in physical stimuli. His "luminosity" corresponds to the "Helligkeit" of Helmholtz, and his "purity" to "Sättigung." He takes even less care than other authors to distinguish between sensation and the stimulus, as the following quotation shows: "the hue of the colour or, as the physicist would say . . . the wave length." Abney ("Colour Measurement and Mixture," 1891) speaks of the "luminosity" of a coloured object, and the "purity" of coloured light, but when giving the results of some of the first actual colour measurements in such units he is sufficiently cautious to give: "Wave length of dominant ray," "percentage of white light," and "percentage of luminosity as compared with white." While he was very sparing in the use of terms which might have a psychological meaning, such as "purity" and the like, he thought it quite legitimate to connect sensation and stimulation in quite an arbitrary way, as Helmholtz did, by the postulate that equal stimulation of all three primary sensations of the trichromatic theory shall produce white. Moreover, the white was perfectly arbitrary; in Abney's case it was the white sensation evoked by the light from the crater of his carbon arc.

In passing, the distinction between various meanings of "white" may be made clear. A surface which reflects diffusively and non-selectively, and has a high albedo or reflection coefficient, is usually described colloquially as white. To the psychologist, however, white is sometimes a hueless sensation of light which happens to be brighter than any other sensation present in consciousness. Frequently, the distinction is not pointed out, and misunderstanding results. To the present writer the simplest conception to appeal to a physicist seemed to be that of the "whiteness" of sunlight (probably a psychologist would prefer to speak of "greyness"), which we learn to recognise in the whiteness of clouds and mist, and in the appearance of all diffusely reflecting and non-selective surfaces. The sensation due to the *light* is the first thing to grasp.

The importance of the "hue, saturation, and brightness" classification of colour is revealed in the colour charts which have been prepared on this basis, and the corresponding commercial colour notations. One of the most notable is that of Munsell, who employs the terms "hue," "chroma," and "value," where the latter two terms correspond to our previously used "saturation" and "brightness." This colour chart, which I have described elsewhere,[1] is in use for commercial purposes. Others on similar lines are also extant.

It will be realised from the foregoing notes that some co-ordination in the use of terms is extremely desirable, and to this end a committee of the Optical Society of America, under the chairmanship of Prof. L. T. Troland, published a report[2] in August 1922 which suggests

[1] "Colour and Methods of Colour Reproduction." Blackie, 1923.
[2] Journal Opt. Soc. Amer., Vol. 6, No. 6, 1922.

definitions for the three variables of colour *sensation*. They are as follows :

1. Brilliance is that attribute of any colour in respect of which it may be classed as equivalent to some member of a series of greys ranging between black and white.

2. Hue is that attribute of certain colours in respect of which they differ characteristically from the grey of the same brilliance and which permits them to be classed as reddish, yellowish, greenish, or bluish.

3. Saturation is that attribute of all colours possessing a hue, which determines their degree of difference from a grey of the same brilliance.

The reason for discarding the terms brightness and luminosity is that both these terms have received technical definitions [3] in connexion with photometric measurements. The Committee would retain the term saturation for the subjective attribute of colour sensation, while allocating the word purity to the "ratio of homogeneous to total radiation in the stimulus." According to the report, any definite physical application of these terms (brilliance, etc.) will "corrupt" them. Many other colorimetric matters and experimental methods are also dealt with in the report.

For practical colour measurement it is necessary to distinguish between the measurement of a colour stimulus such as obtained from the field in a spectroscope, and the measurement of reflected body colour. For the latter case the report describes the specification of colour in terms of (1) luminosity, (2) dominant wave length, (3) per cent. hue. Presumably the former case would best be met by using the term "brightness," but the use of the physical terms is still very variable. The colloquial use of the word "luminosity" is a little against its use as a contraction for "relative luminosity as compared with white."

We have not up to this point discussed the scales of measurement. Just as temperature may be measured in the mercury scale, the hydrogen scale, the platinum scale, and so on, it is possible to measure quantities like brightness on various scales.

The physicist will undoubtedly adopt the ordinary photometric luminosity scale for all colorimetric purposes in which instrumental measurement is required. On the other hand, other scales more nearly related to psychological experience, but still essentially arbitrary, will be far more valuable in the preparation of colour charts, as Ostwald points out.

The nomenclature of Ostwald [4] seems at first somewhat different. He is concerned only with body colours having reflection coefficients between 0 and 1. A grey reflects a fraction w of the incident white light as compared with a quantity 1 reflected by a perfectly reflecting and diffusing surface. The other portion s is absorbed ; then $w+s=1$, where w can be called the white content and s the black content of the grey. Ostwald adopts a scale of greys in which the white contents vary geometrically ; these are called a, b, c, d, etc.

In the case of a colour showing hue, the reflected portion is divisible into two parts, v due to the pure hue and w to more or less white. Hence the equation above becomes $v+w+s=1$. w and s are the white and black contents as before. Colour is specified by its dominant hue and its contents of "full colour" (Vollfarbe), and white. Ostwald criticises Helmholtz for not realising that the "black content" is an essential factor in the appearance of a surface in an ordinary case where colour contrasts are manifest in the field of vision, but Helmholtz was concerned only with the variation of the elements of sensation, and his employment of the term "Helligkeit," signifying absolute light strength, was therefore quite correct while a single sensation was discussed apart from contrast effects. Ostwald's system has been employed in his "Farbenatlas," which gives 2500 indexed colours. A system of colour measurement has also been developed.

While the report of the Colorimetry Committee has put psychological nomenclature in order, the physicist will feel that the use of terms such as white, grey, and the like in fundamental definitions is highly unsatisfactory. For purposes of colorimetry psycho-physical measurements are necessary, and it seems necessary to choose units and formulate definitions which, although possibly arbitrary, are founded securely in physical facts wherever this is possible. In thinking over the matter for the purposes of the book to which reference was made, it appeared to the present writer that the only way to discuss a sensation for purposes of measurement is by reference to an arbitrary physical stimulus which evokes this sensation (or something near it) in the normal subject. Hence white was defined by reference to the colour of sunlight, an arbitrary but definite step. The alternative is the adoption of the results of such lengthy statistical work as that of Priest on "the spectral distribution of energy required to evoke the grey sensation" (Bureau of Standards, Scientific Papers, No. 417). The term "brightness" can be given its usual photometric significance, but there is still the difficulty of finding a suitable term for the relative brightness of a diffusely reflecting surface. It seemed that the term brilliance suggested by the American report gave the term required.

Since the issue of the book, this step has been criticised on the ground that the intent of the American definition of the term brilliance is to exclude the idea of a quantity specified or measurable by any reference to stimuli. Certainly if this appropriation of the term is of importance to psychology, physicists must agree upon some other word such as luminosity or value when dealing with body-colour measurement ; but unfortunately the multiplication of terms for identical mental concepts is quite likely to lead to the confusion which the report seeks to avoid. The present writer prefers the careful use of *one* word provided that the manner of its use is indicated, just as is necessary in the case of terms like "temperature" and "distance," which themselves carry no implied reference to any special mode of physical measurement, but are in perfectly arbitrary use in physics. The question needs more discussion before it is finally settled, but the whole matter is of great importance for purposes of colour standardisation and measurement. Until matters are definitely settled we might do far worse than follow Abney in the non-committal terminology mentioned above.

[3] The *Illuminating Engineer*, Vol. xv. No. 8, p. 227. The definition of "brightness" is given there, but "luminosity" is not defined in British practice. Colloquially, it refers to self-luminous surfaces. The American report says: "*Relative* light quantities are called *luminosities*."

[4] For a concise statement of Ostwald's theory see "Die Grundlage der messenden Farbenlehre." (Barth, Leipzig, 1921.)

The Trend of Development of Marine-Propelling Machinery.

THE eleventh Thomas Hawksley lecture was read before the Institution of Mechanical Engineers on Friday, November 7, by Engineer Vice-Admiral Sir George G. Goodwin, and dealt with the development of marine-propelling machinery. Whilst naval conditions impose restrictions on the design of machinery, both warships and vessels of the mercantile marine must possess the qualities in their machinery of reliability, endurance, durability, and economy, each in high degree. The best economical performances are generally obtained in the merchant service, where machinery is designed for economical running at steady speed. In warships, economy at full power is necessary in order to keep down the weight of the boiler installation; most of the steaming is done at powers so low as one-tenth, or less of full power, and economy at these low powers is also of great importance. Both desires cannot be met completely, and a compromise is arranged.

Marine-propelling machinery develops in warships by the striving for high power on low weight per horse-power, involving the development of high class and special materials, and by the concurrent aiming at the most economical running under very varying conditions. In merchant ships, where weight is allowed on a more generous scale, and steady running is the rule, the development is by the efforts to reduce fuel consumption and, so far as other conditions will allow, by arranging the design so as to enable the machinery to be manufactured, but manufactured properly, at low cost, and to be kept running efficiently with a low repair bill and other running costs.

At present none of the British surface fighting ships is propelled by reciprocating steam engines; these have disappeared entirely except in a few auxiliary vessels and non-fighting craft. All are now fitted with turbines, the later vessels being all-geared, that is, all the turbines in the ship are geared down to drive the propeller; there are now no partially geared turbines in the Navy.

Lloyd's Register Book for 1924–5 shows that the tonnage afloat is divided between the different types of propelling machinery as follows: steam reciprocating engines, 50,742,758 tons; steam turbines, 8,795,584 tons; motors, 1,975,798 tons. The percentage tonnages for five years is divided as follows:

Year.	Steam reciprocating, per cent.	Steam Turbines, per cent.	Motors, per cent.
1918–19	70	28	2
1919–20	57·4	30·7	1·9
1920–21	73·6	23·3	3·1
1921–22	56·4	34·6	9·0
1922–23	52·3	37·4	10·3

These figures show the preponderance of reciprocating engines in the mercantile marine, and that this type is still being built to a larger extent than all other types. But very little development is taking place in reciprocating machinery, and the ratio of tonnage fitted is a falling one. The engine has great advantages but also grave disadvantages. The anticipated better economical performances of the fast-running geared turbine and slow-running propeller have been realised and the direct driving turbine may be regarded as quite obsolescent for marine purposes, and indeed obsolete so far as manufacture is concerned, especially as the geared type lends itself to further improvement, which cannot be developed in the older type.

In a paper read before the Institution of Naval Architects in 1920, Engineer-Commander Tostevin states that there were then 600 sets of mechanical reduction gearing in service in the Navy. There had been trouble in a few cases only; six instances had occurred of fractured pinion teeth, and two of these had taken place during service and the others during trials before the receipt of the machinery by the Admiralty. Some of the later merchant ships have not been so fortunate, and several cases of cracked and fractured teeth have been reported. Facilities have been freely given all round to assist in the investigation of the behaviour of the gears in the merchant service as compared with those in the Navy, and although general agreement as to the cause has not been reached, the discussions have brought to light much valuable information. It may be noted that double-reduction gears were fitted in the merchant vessels where the mishaps occurred, whilst the Navy has generally single-reduction gears. Failure almost always occurred by fracture of the pinion teeth and rarely, if ever, by fracture or permanent deformation of the wheel teeth. No case of faulty or fractured gearing has been reported since April last, and confidence is being rapidly restored.

The inherent disadvantages of electric and hydraulic transmission have outweighed their known advantages, and these alternatives to mechanical gearing have not been adopted in this country.

There is a field for development in point of economy by increasing the temperature range by the adoption of higher boiler pressures, or higher superheat, or both. The steam turbine is specially suitable for both, or either. Whether we are yet ready for the adoption of materially higher boiler pressures afloat is a little problematic; past experience calls for caution, but the matter is receiving consideration. In the merchant service the benefit of superheating has been realised to a greater extent than in the Navy. A recent trial under normal sea-going conditions of a single screw ship with all-geared turbines of 3000 shaft-horse-power, with steam at the high-pressure first expansion of 165 lb. per sq. in. and 200° F. superheat, with exhaust pressure of 28¼ inches, gave a steam consumption for the turbines only of just over 9 lb. per shaft-horse-power per hour. Sir Charles Parsons states that the consumption should be about 8 lb. in the case quoted, hence there is still scope for improvement.

Sir George Goodwin also reminds us that development in one respect must be accompanied by developments in other respects, and cites the development of the single-collar thrust block in time to take the thrust from a geared turbine installation of 38,000 shaft-horse-power passing through a single shaft.

Auxiliary machinery and motor propulsion machinery were also dealt with in the lecture. There are two recent ventures of interest: (1) A combination of

heavy oil engines with electric transmission. (2) The transmission of the power of a fast-running heavy oil engine through mechanical gearing.

Sir George Goodwin has come to some conclusions regarding the future. These are as follows:

(1) The reciprocating steam engine will be the most common type in the mercantile marine for some years yet. It is not likely to be developed in power, and not in economy of fuel consumption to any marked degree.

(2) Geared steam turbines must continue to be the engine for all ships of high power, as in the Navy. Its development will be in the direction of improving its fuel consumption by use of superheated steam and by attention to its details and auxiliary machinery.

(3) The heavy oil engine, having established its reputation for reliability, will, having regard to its low fuel consumption per horse-power, be the propelling engine of an increasing number of cargo ships and ships of low and moderate power, but its rate of increase of use will be retarded while its cost remains high, and efforts will be made to reduce the cost by increasing the power per cylinder by the several stages leading to the double-acting two stroke cycle engine.

Development will require a great deal of engineering research and experimental work, and also probably fundamental research in certain branches of pure science. Co-ordination in the different fields of research and with the engineer has been accomplished in some branches of engineering in the United States, and Sir George Goodwin invites attention to the system adopted of having an intermediate laboratory separate from the fundamental research station and separate from the factory. Here the results of fundamental research are collected and sifted, and the parts promising to be of service to the engineer are co-ordinated and developed with the help of engineers who know the needs of the factory, and also with the help of others who are expert in the economical side. The results are said to be satisfactory and to justify the cost.

Dielectric Mineral Separation.

By Prof. S. J. TRUSCOTT.

IN the preparation of clean mineral from crude ore, the processes of water concentration and flotation concentration, in combination or separately, achieve all that is required with sulphide ores, the former process being particularly successful in the recovery of coarse and granular mineral, while flotation is equally successful with fine and with the finest mineral. But, with oxide or oxidised ores, though water concentration will generally suffice where the mineral grain is large and remains so during crushing, there is no equivalent of flotation to recover fine mineral or that so fine as to go into suspension. Yet in the dressing of tin and other oxide ores requiring fine crushing, a substantial proportion of the ore passes into the fine condition described as slime, from which it is at present impossible to make a satisfactory mineral recovery. Again, the recovery of the vanadium mica, roscoelite, from the sandstone in which it occurs typically in the United States is not at present possible by any dressing process, because the roscoelite is friable and light; such vanadium deposits, large as they are, at present lie idle. Even where the mineral grain is sufficiently large it sometimes happens, and particularly with minerals of the rare metals, that water concentration will yield a complex concentrate of two or more minerals with properties of density, magnetic permeability, electric conductivity, etc., so similar that no one of the presently applied methods of dressing is effective in separation. Thus, some vanadium, uranium, and molybdenum minerals occurring together largely remain inseparable; and some alluvial tin concentrates contain rare minerals from which it is difficult to free the tin.

Given this position, any new process based upon physical differences between minerals not yet used in dressing, and disclosing possibilities of useful application in the field as yet unoccupied, is welcome. Dr. H. S. Hatfield, in a paper read before the Institution of Mining and Metallurgy in February last, brought forward such a process, one based on the differences in inductive capacity between minerals and one which he termed "dielectric mineral separation," substances being dielectrics by virtue of their property to propagate electric forces through themselves by induction. The "specific inductive capacity" may be considered to be a particular range of the more general "dielectric constant." Conductors may be considered to have an infinitely high dielectric constant; but insulators are the characteristic dielectrics.

As groups, the sulphide ore-minerals are conductors, the oxide ore-minerals poor conductors, and the gangue minerals are non-conductors. Actually, the oxide ore-minerals have dielectric constants of the order of 20-30, while the constants of the gangue minerals are of the order of 5, that of air being unity. Situated in an electric field in air, the forces acting on particles of ore are such that all would be attracted to the electrode with forces so much of the same order that gangue and mineral could not be differentiated. The position is different in a magnetic field, in that gangue minerals have a magnetic permeability practically the same as that of air and accordingly behave as non-magnetics. In dielectric separation there are no non-electrics comparable to the non-magnetics of magnetic separation.

Dielectric separation therefore employs a liquid dielectric having a constant intermediate between that of the gangue and that of the mineral, in which medium the gangue is repelled and the mineral attracted to the electrodes. Water is useless, because when pure its dielectric constant is too high, and when impure it becomes a conductor. Dr. Hatfield has chosen to mix kerosene and nitrobenzene in proportions such as in each case give the desired constant, that of kerosene being about 2 and that of nitrobenzene about 36.

The necessary electric field is obtained by a single-phase alternating current of about 200 volts and 150 frequency, brought to electrodes about a couple of millimetres apart. These electrodes may be parallel wires, or one wire coiled around a straight wire, or

points on parallel plates. With the field in being and the crushed ore passing, the mineral is held while the gangue falls through. When loaded the circuit is broken and the mineral drops. Conducting minerals are rendered innocuous by covering one electrode with paper.

There is difficulty in this process in that the dielectric constant of a mineral is liable to vary according to its previous treatment in crushing and in exposure; it varies also with the frequency: these are points upon which careful work is necessary. There is also economic difficulty in recovering the expensive medium which passes out both with the mineral and with the gangue, these two products having to be filter-pressed and then subjected to heat to distil the remaining liquid. It is claimed that a similar difficulty has been successfully met in removing sulphur from kerosene with added colloidal silica, the silica being recovered dry and in a condition to be used again.

The process differs, on one hand, from ordinary electrostatic mineral separation in that it is not operative by reason of charges acquired by contact, and, on the other hand, from cataphoresis in that this latter is a migration of particles towards an electrode by reason of charges they possess of themselves. In dielectric separation there is no question of electric charges; the particle in the electric field is in an analogous position to ore in a magnetic field, only that there is both attraction and repulsion in dielectric separation, whereas with magnetic separation there is rather differential attraction, magnetic repulsion being a rare phenomenon.

Obituary.

Sir Maurice Fitzmaurice, C.M.G., F.R.S.

BY the death of Sir Maurice Fitzmaurice on November 17, the engineering world has lost a leader of outstanding ability who served the country in many capacities and whose name will always be associated with two great undertakings, the construction of the Assouan Dam on the Nile and the extension of the main drainage of London. He was also associated with railway development and harbour and dock work in various parts of the world. In 1916 he was chosen to succeed Mr. Alexander Ross as president of the Institution of Civil Engineers, from which he received the Telford and Watt Gold Medals, and three years later he was admitted a fellow of the Royal Society, a distinction also conferred upon many of his predecessors such as Telford, Walker, Sir Benjamin Baker, Rennie, Hawkshaw, Robert Stephenson, and Sir William Preece.

The son of Dr. Robert Fitzmaurice of Cloghers, Tralee, Sir Maurice Fitzmaurice was born in Co. Kerry on May 11, 1861. At Trinity College, Dublin, which has possessed a school of engineering since 1847 and where for thirty years Samuel Downing occupied the chair of engineering, he took the degrees of M.A. and Master of Engineering, and then became articled to Sir Benjamin Baker, who at that time was engaged with Sir John Fowler on the Forth Bridge. This was the first great work with which Sir Maurice was associated. During the 'nineties he was in charge of construction work in Canada and elsewhere, and then in 1898, at the age of thirty-eight, he received the important appointment of Chief Engineer to the Egyptian Government for the construction of the great Assouan Dam, with which Sir William Willcocks, Sir Benjamin Baker, and Sir John Aird were associated. This Dam, once described as "one of the grandest engineering undertakings of our time," is 6400 feet long, has 180 sluices, and contains more than 1,000,000 tons of granite. Begun in 1898, it was completed in 1902, Sir Maurice's work being recognised by the award of the C.M.G.

Returning home, Sir Maurice was appointed successor to Sir Alexander Binnie as Chief Engineer of the London County Council. In this capacity, he was responsible for the construction of the Rotherhithe Tunnel, the Embankment in front of the new County Hall, the new Vauxhall Bridge, and the subway for trams under Aldwych and Kingsway to the Embankment. During his period of office, 1902–1912, he also carried through the duplication and extension of the whole drainage system of London at a cost of about 4,000,000*l*. Until 1847 the sewage of London was discharged direct into the Thames, and it was under one of Sir Maurice's predecessors, Sir John Bazalgette, that the great sewers were carried down to Barking and Cross Ness, and in Sir Maurice's report to the Council in 1912 will be found many details of the growth of the wonderful network of sewers which carry off the drainage of London and the methods used for its disposal.

During the latter part of his career, Sir Maurice was a partner in the firm of Coode, Fitzmaurice, Wilson and Mitchell, consulting engineers to the Crown Colonies and to the Sudan Government for the Blue Nile Irrigation Works, and chief engineers of the national harbours at Dover and Peterhead. He also acted as chairman for important committees appointed by the Admiralty, War Office, Foreign Office, and Board of Trade; on two occasions he visited the British front in Flanders to advise on questions of drainage, and served on the International Technical Commission of the Suez Canal. Knighted in 1912, Sir Maurice received many honours, among which was the honorary membership of the American Society of Civil Engineers. He was the author of works on bridges and drainage, while his presidential address to the Institution of Civil Engineers contains much valuable advice to young engineers, the results of his own experience. "In looking back," he said, "over the great number of engineers whom I have come across in works and in office, I cannot bring to mind any case of a hard worker who has really failed."

We regret to announce the following deaths:

Mr. Romeyn B. Hough, author of the "Handbook of Trees of the Northern United States and Canada," who was known also for his remarkable fascicles of sections of North American woods, aged sixty-seven.

Dr. E. König, of the photographic department of the dye-works of Meister, Lucius and Bruning, Höchst-am-Main, whose name is known in connexion with the pinatype process, and with sensitisers and desensitisers, on October 29, aged fifty-four.

Current Topics and Events.

IT is of interest to recall that the date November 23 marks the 260th anniversary of the publication in 1664 of that rare and notable folio by Robert Hooke, entitled "Micrographia: or some Physiological Descriptions of Minute Bodies made by Magnifying Glasses, with Observations and Inquiries thereupon." The issue was licensed by Viscount Brouncker, P.R.S. Hooke, who was born in 1635, at Freshwater, Isle of Wight, died in 1703. He was associated in intimate fashion with the early founders of the Royal Society—Moray, Wren, Boyle, Evelyn, and others—and worked with amazing industry to promote its aims. The lineaments of this remarkable man have not been bequeathed to posterity, since no authentic portrait of him exists. Sir Robert Moray had originally suggested Hooke, in 1662, as a curator of experiments to the Royal Society, putting it that "Mr. Hooke should come and sit amongst them," but it was not until November 23, 1664, that the president was desired to declare to the whole Society that the council thought good to have a curator by office, and Dr. Wilkins was deputed to submit that "Mr. Hooke standing for a curator's place be this afternoon nominated." Robert Boyle was thanked for dispensing with his services, in favour of the Society.

THE "Micrographia" contains a dedication to the King, this subscribing to the current flamboyant style. "There are, Sir" (Hooke says) "several other of your Subjects, of your Royal Society, now busie about Nobler Matters: The Improvement of Manufactures and Agriculture, the Increase of Commerce, the Advantages of Navigation: In all which they are assisted by your Majestie's Incouragement and Example. Amidst all those greater Designs, I have presumed to bring in that which is more proportionable to the smalness of my Abilities, and to offer some of the least of all visible things, to that Mighty King that has established an Empire over the best of all Invisible things of the World, the Minds of Men." The Royal Society is given a special dedication, Hooke informing them that "the Rules you have prescrib'd yourselves in your Philosophical Progress do seem the best that have ever yet been practis'd. And particularly that of avoiding Dogmatizing." A long and somewhat drawn-out preface to the reader follows. Of Wren and Wilkins, Hooke has much to say in eulogy and evident friendship. There scarce ever met, he affirms, in one man (Wren) so great a perfection, such a mechanical hand, and so philosophical a mind.

BORROWING the title of a world-known story, "A Tale of Two Cities," Mr. H. S. Pritchett discusses in the November issue of *Scribner's Magazine* the application and function of Benjamin Franklin's trust for the cities of Boston and Philadelphia, the provisions of which were set forth in a codicil to his will made some eight months prior to his death. The recent celebration of the centenary of the Franklin Institute of Philadelphia gives the article special point. The detailed information respecting Franklin's philanthropic foundation is, indeed, welcome and timely. Needless to say, two other cities hold Franklin in honoured remembrance. He lived in London eleven years, was elected a fellow of the Royal Society, and served on its council. The Society would take no fees from him. The Paris National Assembly wore a badge of mourning for three days after his death; Condorcet pronounced a eulogy before the Academy of Sciences. Franklin's design was to benefit Boston and Philadelphia through the creation of a money trust for each, which, however, contained at the same time a hard and fast plan, operative for one hundred years, with a contingent second centennial period. He wished to form the mind of youth and conduce to the material prosperity of youth; also to encourage the projection of works of public utility of such nature as might lead to the comfort and convenience of the inhabitants of the cities named. Without stretch of imagination he would seem to have preceded Mr. Carnegie and Mr. Rockefeller. The story of these bequests, their limitations, the difficulties encountered in their administration, and, not least, the economic and social changes which have affected them, form, in the hands of Mr. Pritchett, an interesting record, throwing as they do much light upon the question of the institution, management, and obligations which arise therefrom.

ELECTRIC supply authorities are sometimes required to give a supply of electricity to districts at a great distance from the generating station, although the probable demand is small. In these cases it does not pay them to erect a manually operated substation, and a completely automatic substation is too expensive. Mr. Chattock, the electrical engineer to Birmingham, deserves great credit for doing valuable pioneering work with small automatic substations equipped with mercury vapour rectifiers of the glass-bulb type. This apparatus statically transforms alternating current into direct current. When a mercury arc exists in a vacuum under certain temperature conditions, it acts like a valve, allowing current to flow through it in one direction and not in the other. The cathode bath of mercury is the positive pole of the direct-current circuit. If the vacuum fail for any reason, then a violent short circuit occurs, but luckily this rarely happens. In a paper read to the Institution of Electrical Engineers on November 20, Mr. Rogers stated that in the case of glass bulbs for 230 volts, no single instance in his experience of a short circuit has occurred. This paper will be of immediate value to engineers, as not only are the arrangements for the automatic control of these rectifiers given in full, but also schedules of the complete costs of rectifier substations. A method is given in the appendix of supplying direct current at 550 volts to a six-mile length of double tramway track by means of semi-automatic rectifier substations. The method is both simple and cheap, and probably will have applications in the immediate future.

THE decision of the editors of the *Irish Naturalist* to cease publication of this journal with the December number will be learned with deep regret by the many readers in Great Britain and elsewhere who have followed the admirable work done by the magazine in promoting the study of the fauna of Ireland for a period of thirty-three years. It has been unable to recover from the vicissitudes due to the War, and increased costs of production, with the loss by death or otherwise of a large body of its former supporters, have combined to render continued publication impossible. An author index to the last eight volumes, on the same lines as that for the first twenty-five, will be issued with the concluding number of the current volume. A subject index and title index to the whole series is contemplated if sufficient financial support is forthcoming.

THE remarkable and well-known collection of stone implements and other Irish antiquities formed by Mr. W. J. Knowles of Flixton Place, Ballymena, Ireland, was sold by auction at Sotheby's on November 17 and three following days, the total amount realised being 4005*l*. The more important stone implements were purchased for the Belfast Museum, including a fine kite-shaped lance-head of flint found between Bellaghy and Castle Dawson (25*l*.), one of gray flint polished on both sides, 6 inches long, from Tyhorney (25*l*.), a spear-head of elongated kite-form, 7½ inches, from Carndon (10*l*.), chipped axe of basalt, 13 inches long, found at Armoy (10*l*.). Several of these implements were figured in the Journal of the Royal Anthropological Institute, vol. xxxiii. The Ashmolean Museum obtained two rare pieces—a cauldron of thin sheet bronze formed of four riveted plates found near Portglenoue (50*l*.), and a heart-shaped bronze fibula with triangular plate of the second century A.D. (17*l*. 10*s*.). A Celtic quadrangular iron bell with clapper fell to Belfast Museum (25*l*.).

FEW educational organisations have done more valuable work than has the School Nature Study Union, which celebrated its coming of age in September last. Founded in 1903 by a small band of enthusiasts, of whom the leaders were Miss Kate Hall and the Rev. Claude Hinscliff, with the primary object of bringing a breath of the country into the drear and drab lives of the children of the London slums, it has grown into a large and vigorous organisation permeating the educational system of the whole of England, endeavouring to foster in children a real love of the natural world around them, an appreciation of its beauty, and an interest in its manifold workings. The special anniversary number of its official organ, *School Nature Study*, issued to commemorate its coming of age, contains much interesting matter on various aspects of nature study, and a review of the growth of the Union and of the work that has been accomplished. Three articles deserve special notice. Prof. J. Arthur Thomson has rewritten his pamphlet on "The True Inwardness of Nature Study," and, in its revised form, it is worthy of the close attention of all who desire to see an extended system of biological teaching put into practice. It is a clear and reasoned statement of the objects, methods, difficulties, and potentialities of nature study, and embodies the ideals of the Union for which it was written.

THE other two articles in this anniversary issue of *School Nature Study*, by the president of the Union, Dr. Chalmers Mitchell, on "Observation and Theory," and Prof. J. B. Farmer on "Teleology in Nature," bear on the same problem and also contain timely warning against one of the greatest dangers of nature study in inexperienced hands, namely, the attempt to interpret the facts observed, the tendency to warp the powers of observation through the influence of preconceived theories, and the interpretation of animal and plant behaviour on anthropomorphic lines. Dr. Chalmers Mitchell deals with the general problem; Prof. Farmer is concerned mainly with the dangers of teleology, the appeal to design or purpose as an explanation of structure or behaviour. For these friendly warnings, so timely given, the Union and its supporters should be grateful. We join in the many congratulations which the Union has received on this special anniversary of its foundation. With the ideals before it so high, with the enthusiasm of its executive so keen and whole-hearted, and with a growing volume of support from biologists on one hand and educationists on the other, the Union in its maturity should bring to fruition the seeds so diligently sown in its infancy and adolescence.

A CHADWICK public lecture on "Smoke: its Cause, Nature, Effects and Methods of Prevention" was delivered by Prof. J. B. Cohen on Wednesday, November 19. Prof. Cohen stated that soot from factory chimneys is very different in character from that from domestic fireplaces where raw coal is burnt. In the former case, owing to the high temperature and strong draught, the volatile portions of the coal are mainly consumed, whilst the draught carries off mechanically fine mineral dust and grit mixed with carbon containing little tar. Domestic soot, on the other hand, may contain as much as a quarter of its weight of tar. It is this tar which causes the soot to cling, accumulating with time and blackening surfaces with a varnish which is not removed by rain. Vegetation suffers in several ways from the presence of smoke. If the light is partially cut off by the pall of smoke, or if the leaf (more especially of evergreens) is blackened by a coating of soot, or again if the stomata are blocked with tar, the plant must suffer. Again, the plant is affected by the acid soot, and also by the sulphur acids which pass into the air from burning coal and are washed down by rain. The effect of this acid is to corrode the leaf, which withers and falls much earlier in and near a town than in the country. Moreover, the acid percolating through the soil destroys certain organisms and enzymes concerned in the assimilation of the soil constituents, and many grasses, vegetables and flowering plants succumb. Even the colour of flowers is affected. The observations of Sir Frank Baines have also made it evident that the sulphur acids from coal attack masonry, while fabrics,

leather bindings and metal work are being similarly attacked. Passing to remedial measures, Prof. Cohen stated that in his opinion the situation could be much improved by the production of cheaper gas, coke, and electricity, while local authorities should encourage their sale and exercise to the full their powers under the Public Health Act of 1875 to stop unnecessary smoke from boiler chimneys.

THE opening meeting of the Illuminating Engineering Society on November 18 was, by custom, devoted to reports of progress and the exhibition of novelties. Mr. Leon Gaster in his opening address remarked that the vacation had been a period of exceptional activity. Illumination had been dealt with at the World Power Conference, the meetings of the International Illumination Commission and the International Conference on Industrial Hygiene in Geneva, and at the Conference afterwards arranged by the Society at the British Empire Exhibition. At Geneva an excellent opportunity of interesting hygienists in lighting problems had been presented, and good lighting is now definitely accepted as an element indispensable for health, safety, and efficiency. Developments abroad had been rapid, and in the present year an Illuminating Engineering Society had been formed in Austria. A report presented by the Committee on Progress in Electric Lamps and Lighting Appliances directed attention to the steady advance towards higher values of illumination, and quoted examples of the general tendency to utilise light in a more scientific manner. The exhibits after the meeting as usual covered a wide range, including new reflectors and luminous signs, and a motor-car headlight specially designed to overcome the dazzle difficulty. Mr. W. G. Raffe dealt with the psychology of illumination, and Miss Mary Wurm gave an address on stage lighting in connexion with music, illustrating her remarks by experiences in various Continental theatres.

IN the unavoidable absence of Lord Weir, Mr. H. B. Weeks presided at the third annual meeting of the Cast Iron Research Association in London on November 19. The chairman laid stress on the great progress made during the year, and summarised the main developments, referring particularly to the extended research programme and the establishment of a laboratory. Sir John Dewrance was elected president of the Association for the period 1924–26, and the following were elected vice-presidents: Mr. Geo. Pate (Falkirk), Mr. Summers Hunter (Wallsend-on-Tyne), Mr. F. W. Firth (Sheffield), Mr. C. E. Lloyd (Dudley), and Mr. W. B. M. Jackson (Chesterfield). Commander C. W. Craven and Prof. T. Turner were re-elected vice-presidents. A great tribute was paid to the services rendered to the Association by the retiring president, the Rt. Hon. Lord Weir of Eastwood, who was elected an honorary member. Mr. A. J. Burn, Mr. F. J. Cook, Mr. T. Donaldson, Mr. N. B. Ellington, Mr. J. Haigh, Major C. Howl, and Mr. M. Riddell were re-elected to the council. Dr. W. Rosenhain and Prof. T. Turner were elected honorary members, and Dr. Rosenhain spoke, expressing the hope that there would be even greater co-operation in future between the Association and the Ferrous Alloys Research Committee. Delegates nominated by the leading technical institutions were also elected at the meeting.

THE next Congress of the Royal Sanitary Institute and Health Exhibition will be held at Edinburgh on July 20-25, 1925, by invitation of the Magistrates and City Council.

THE following have been elected officers of the Cambridge Philosophical Society for the session 1924–1925: *President*, Prof. J. T. Wilson; *Vice-Presidents*, Prof. J. Barcroft, Mr. C. T. Heycock, Dr. G. T. Bennett; *Treasurer*, Mr. F. A. Potts; *Secretaries*, Dr. F. W. Aston, Mr. J. Gray, Mr. F. P. White; *New Members of the Council*, Dr. A. B. Appleton, Dr. C. D. Ellis, Mr. F. F. Blackman, Mr. C. T. R. Wilson, Mr. J. E. Littlewood, Mr. G. Udny Yule, Prof. E. A. Milne.

THE *Chemiker Zeitung* reports that Prof. F. Paschen, formerly director of the Physical Institute of the University of Tübingen, was installed on November 1 as president of the Physikalisch-Technische Anstalt, Berlin. The same issue also records the appointment of Herr Geheimrat Wiedfeldt, German Ambassador to Washington, to the head of the directorate of the firm of Krupp in Essen-Ruhr. Dr. Bruhn retires from the board of directors, in order to become the representative of Krupps in Berlin, in succession to Dr. Kurt Sorge, who has resigned.

A NEW expedition to the Arctic is being planned by Mr. Lauge Koch, the Danish explorer. According to the *Geographical Journal* for November, the objects will be mainly geographical and cartographical, and the field of work will be Grant Land and other islands of Arctic Canada, where Mr. Koch proposes to investigate and map the mountain range which he believes to be a continuation of those he explored in Northern Greenland and a section of a great arc that continues through Spitsbergen, the Shetlands, Scotland, and Wales. No date for the departure of the expedition has yet been fixed.

THE Royal Geographical Society, in conjunction with the University of London, has arranged a meeting of a special character to be held at the Central Hall, Westminster, on December 1. M. Albert Kahn, who is already well known for the establishment of the Albert Kahn Travelling Fellowships and similar works for the promotion of international comity, is sending to the meeting a number of photographs taken in natural colours by his direction in various parts of the world. These will be projected on a screen in four groups illustrating European scenery, the relation of environment to man, modern architecture, and China, and will be described by Mr. A. Ogilvie, Mr. L. H. Dudley-Buxton, Mr. E. A. Benians, and Prof. P. M. Roxby, all of whom have held Albert Kahn Travelling Fellowships.

WE learn from *Science* that an Institute of Research has been established by Lehigh University, Bethlehem, Pennsylvania, "to encourage and promote scientific

research and scholarly achievement in every division of learning represented in the organisation of the university; and in recognition of the need for further and more exact knowledge in science and in the applications of science to the affairs of modern life." The Institute will be controlled by an executive board including heads of the faculties of Lehigh University, and it is hoped to afford training in research methods to the staff of the University and the Institute, to graduate students of the former, and to special investigators. The New Jersey Zinc Company has already founded a research fellowship in science and technology in the new Institute. Bulletins or reports on the progress made in problems attacked will be issued from time to time.

MESSRS. Dulau and Co., Ltd., 34 Margaret Street, W.1, have just circulated their Catalogue No. 119, giving the titles of some 1400 second-hand books and serials relating to astronomy, dialling, meteorology, aviation, physics and chemistry, mathematics and mechanics, and fen drainage, which they have for sale.

THE Cambridge University Press announce for early publication "A History of British Earthquakes," by Dr. C. Davison, the aim of which is to record all known British earthquakes, to trace the zones in which crust-changes have recently occurred and in which the faults are yet alive, and to discover some of the laws that rule the growth of faults.

THE Cantor Lectures on "Colloid Chemistry," which were given by Dr. E. K. Rideal at the beginning of the year, have been published in three recent numbers of the Journal of the Royal Society of Arts (Oct. 17, 24, and 31). Dr. Rideal's review included such topics as adsorption, methods of preparation, stability of sols, emulsions, soaps, etc., practical applications of the features discussed being frequently given.

THE Oxford University Press will publish at the beginning of December a limited edition of "The History of Aeronautics in Great Britain from the earliest period to the latter half of the Nineteenth Century," by J. E. Hodgson. The work will include chapters on the development of international aeronautics, an annotated list of papers read before the Aeronautical (now the Royal Aeronautical) Society between 1866–93, and a selected bibliography.

Our Astronomical Column.

A STUDY OF STELLAR MOTIONS.—The *Scientific Monthly* for November contains an interesting analysis of stellar velocities by Dr. Gustaf Strömberg. He forms *velocity surfaces* for different groups of stars by imagining the bodies forming a group to start from a common point at the same instant; then after moving each with their proper speed for the selected unit of time, the curve or surface drawn through them gives a graphic representation of the velocity distribution.

These surfaces in most cases are considerably elongated not only in sections perpendicular to the galactic plane (which we might foresee *a priori*) but in the galactic plane itself. This is so far in accord with Schwarzschild's ellipsoidal hypothesis, but a considerable deviation from such a symmetrical form is found, which is especially notable when stars of high velocity, more than 100 km./sec., are examined. They are found to be practically all moving towards one hemisphere. A similar want of symmetry is found in many other distant objects.

The author gives a tentative explanation, supposing that some fundamental system of reference exists in space, and that high velocities relatively to it are far more rare than small velocities. He gives an illustration; supposing a ship moving rapidly through the air, then various classes of objects on deck are variously affected by the strong draught produced, some moving with the ship, others keeping their position in the air, while others have intermediate motions. If several ships are postulated, a close resemblance to the observed stellar motions would arise. The paper closes with some discussion on the bearings of these results on Einstein's general theory of relativity.

MARTIAN PHOTOGRAPHY.—Two very interesting series of Martian photographs are reproduced and discussed in the October number of Publications of the Astronomical Society of the Pacific. The first, by W. H. Wright, deals with photographs taken with the Crossley reflector at the Lick Observatory in light of three different wave-lengths, (1) ultra-violet, (2) yellow, and (3) infra-red. (1) shows no detail on the disc except the polar cap, and gives a distinctly larger image than the others; (2) agrees with the visual aspect of the planet; (3) shows the dusky regions in an accentuated manner, the polar cap being small and faint. (1) is thought to give a picture of the Martian atmosphere, extending 120 miles above the limb (this is supported by some recent observations of the occultation of Mars, a glow being seen for a few seconds after the disappearance of the disc). It is concluded that the polar cap is mainly an atmospheric phenomenon, but that there is probably a less conspicuous surface cap below it. The darkness of the dusky areas in (3) indicates that their radiations are mainly in the blue and green, agreeing with their visual aspect. Terrestrial landscapes taken from Mt. Hamilton with (1) and (3) show that the distant landscape is wholly blotted out in (1) by the atmospheric veil, while it is clearly visible in (3).

The second series was made by Prof. E. C. Slipher at Flagstaff, with the 24-inch refractor and the 40-inch reflector. The tests with light of different wave-lengths are in full accord with those of Mr. Wright. The pictures are grouped in a manner to bring out the seasonal changes, the dusky areas darkening in the late spring and fading in the autumn; this is in full accord with the vegetation hypothesis. On the whole, these markings and the polar cap have repeated the cycle of change recorded in 1909, the region Deucalion being, however, fainter this year.

Search was made, without success, for the chlorophyl bands in the spectrum of the dusky areas. It is noted that it is much more difficult to detect these in reflected light than in transmitted light.

Prof. R. Trumpler also publishes some simultaneous drawings and photographs made with the 36-inch Lick refractor. The drawings show numerous canals, including some in the dusky areas; traces of several of these can be seen in the photographic reproductions, and the original negatives are stated to show many more. The polar cap had some dark bands across it, and detached white patches at its edges. A small white spot is shown in the middle of Auroræ Sinus, not very far from "Dawes Ice Island."

Research Items.

HOLY WAYS AND HOLY PLACES.—Prof. H. J. Fleure has published in the *Sociological Review* a communication to the Conference on Living Religions, recently held at Wembley, on the origin of sites which are or have been held in special veneration as centres of religious cults. Such centres have to a great extent grown up along routes of trade and intercourse such as can be traced so far back, at least, as the late neolithic and early metal ages. There is evidence for the spread of cultural influences between the Iberian Peninsula, France, western Britain and Ireland, southern Sweden, Denmark, and north-west Germany. The megalithic monuments which mark this spread of culture may well have been stations of men of superior culture to which natives would come to trade, their sanctity continuing down to historic times, as is shown by the records of the early Christian Church. The stations along the route followed by Abram from Haran through Palestine—Shechem, Bethel, Hebron, and Beersheba—gathered traditions of sanctity in course of time. Mecca, a station of sanctity far older than Islam, as is shown by the cult of the Black Stone, is a place of contact on the trade way from Arabia Felix northward. Santiago de Compostella is a focus behind alternative ports going back directly and indirectly to the earlier stone monuments. Similarly St. Davids in South Wales, Canterbury, and possibly St. Andrews, each acted as a focus for sea routes; while Kief analogously is the culture entry for the land and rivers both from the south, by which Byzantine influence reached Muscovy, and from the west. Jerusalem originally was the fortress controlling the trade routes, whether from Hebron to Bethel and Shechem, to Jericho and across the Jordan, or along the western side of the Dead Sea.

GROWTH OF CHINESE.—Dr. S. M. Shirokogoroff and Dr. V. B. Appleton have published in the *Chinese Medical Journal* for May last an analysis of measurements of Chinese children and adolescents ranging in age from three years to twenty in the case of males and eighteen for females. The data investigated cover stature, weight, and growth, and are derived from 873 males and 266 females. It was at once apparent that the growth of females is not the same as males. There is, in the case of males, a regularity in increase of stature, weight, and relative weight. In females this regularity is disturbed at the age of 4 and 17 years in relative weight and at 18 in stature. There seem to be two critical periods in the development of males, at the age of 6 years and 15 years, when the absolute growth is evidently accelerated. The average stature of the Chinese is about 64·5 inches for males. Hence it appears that male stature growth stops at about 21 years. The curve of weight mounts smoothly up to about 17 years, when it nearly stops. For females the growth of stature stops almost completely at 15 and completely at 18. Though no data of adult females are available, the average stature is probably about 60 inches. In weight, the starting weight is as much as 2·5 pounds less than the males, and the growth almost ceases at 15 years.

KEMP FIBRES IN THE MERINO SHEEP.—Prof. Duerden and Miss Ritchie (Union of South Africa, Department of Agriculture, Science Bulletin No. 34) have made investigations into the nature of kemp fibres in the wool of sheep. These are straight, coarse, dull, opaque-white fibres, very brittle and inelastic, and not dyeing like wool fibres in the process of manufacture. Their presence in wool depreciates its value considerably, since it leads to lack of uniformity in texture and colour. The authors find that kemp fibres have a thick central medulla, with hollow interspaces containing inclusions of air, whereas wool fibres are solid, with no medulla and no air inclusions. Their experiments prove that kemp fibres dye just as readily as wool fibres, but that the air inclusions interfere with the effectiveness of the dye, and that the want of uniformity in colour is therefore purely an optical effect. They conclude that kemp fibres represent all that remains of the outer of the two coats of hair which the ancestor of the merino sheep, in common with most mammals, possessed. Under domestication this outer coat has largely disappeared as a result of long selective breeding and the inner coat, wool, alone remains. It is suggested that kemp fibres may be completely eliminated from the fleece of the merino sheep by an intensification of selective breeding and, alternatively, that it may be found possible by experiment to introduce some method for removing all the air from kemp fibres at one stage or other of the dyeing process and thereby secure uniformity of colour.

A GIANT INFLORESCENCE.—The *Gardener's Chronicle* for November 1 contains some very good photographs showing the development of the inflorescence of *Amorphophallus Titanum*, Beccari, in the Botanic Gardens at Buitenzorg, Java, Mr. P. Dakkus, the curator, having recorded in this manner the development of spathe and spadix from bud to maturity between June 5 and 27, 1924. The total height of the expanded inflorescence is recorded as 2·01 metres, the circumference of the spathe 1·30 metres. From temperature readings Mr. Dakkus concludes that but little heat is developed in the tissues during growth, though the data given seem to be obtained simply from readings of the air temperature within the unexpanded spathe. This giant inflorescence has frequently been seen at Kew, and the editor of the *Gardener's Chronicle* reports that a new and large tuber has recently reached Kew. The plant is a native of Sumatra.

THE POISONOUS ACTION OF COPPER AND MERCURY SALTS IN PLANTS.—In view of the growing practice of trying to sterilise seeds before germination, considerable interest attaches to the attempts of H. Lundegårdh to establish some general fundamental points as to the toxic action of the ions of copper and mercury upon the plant (*Biologisches Centralblatt*, 44, pp. 465–487, September 1924). These ions are absorbed very strongly in the fruit coat of wheat grains by a process which is apparently strongly periodic, like the Liesegang ring phenomenon, and the author thinks it is in this case based upon the interference between primary copper absorption and secondary alterations of the degree of swelling of the material of the fruit coat. Germination and germination energy are as a consequence differently affected by different concentration, so that, whilst a very low concentration may be harmful, a slightly higher may be beneficial if anything, whilst a higher concentration again inhibits or depresses germination. Obviously these results may have great bearing upon practice, and show that great caution will be necessary in establishing the concentration of such toxic substances when used in seed sterilisation.

EXPLORATIONS IN THE LIBYAN DESERT.—Mr. Hassenein Bey's account of his journey across the Libyan desert through Kufra to Darfur appears in the *Geographical Journal* for October and November. It is followed in the November number by a long article

by Dr. J. Ball discussing the cartographical results of the journey. Dr. Ball briefly summarises the additions to our knowledge of north-eastern Africa as follows: The true positions of Zieghen and Kufra have been shown to be 100 and 40 kilometres respectively from the hitherto assigned positions. Oases discovered at Arkenu and Owenat open up possibilities of new routes into the unexplored regions of the Libyan desert. A new route with water courses along it has been mapped across the Erdi and Ennedi plateau, and valuable information, including barometric levels, has been collected over a vast region, confirming Col. Tilho's conclusion that there is no possible drainage outlet from Lake Chad in an easterly direction. Two papers follow on the geological data by Dr. W. F. Hume and Mr. F. W. Moon.

Problems of Antarctic Sea-ice.—In "Manchester Memoirs," vol. lxviii., No. 7, Mr. R. W. James discusses some problems of pack-ice, especially in regard to the Weddell Sea. The most interesting part of the paper deals with the salinity of sea-ice. It is well known that pack-ice, particularly in old pressure hummocks, on melting yields water fresh enough to drink. Freshly formed ice yielded on melting a solution with 1·2 to 0·7 per cent. of sodium chloride. Older pack-ice which has been exposed to weathering for at least one summer has a salinity of 0·2 per cent. This old hummock ice has a vitreous appearance and has lost the original fibrous appearance that is characteristic of new ice. One condition of loss of salinity in old ice seems to be elevation consequent on pressure, which enables the included saline liquid to drain by the action of gravity. Mr. James made the interesting observation that even at very low temperatures (*e.g.* – 30° C.) certain of the salts contained in the ice are in solution and may be lost by draining. But he believes that for sea-ice to lose its salinity, exposure to high summer temperatures is also necessary. Tentatively he advances a theory to account for alternate rise and fall of temperature leading to drops of saline liquid descending through the ice without it being actually porous.

The Oilfields of Argentina.—The time was ripe for an up-to-date and authoritative summary of petroleum developments in the Argentine, and Mr. Campbell Hunter's paper, read at the Institution of Petroleum Technologists on November 4, attracted attention because of this, quite apart from the technical interest of the communication. It has been difficult both for science and the oil industry to gauge with any assurance the commercial possibilities of the Argentine as an oil producer, largely because only the broadest facts of essential geology are known, and also because the vicissitudes of past operations there have proved somewhat bewildering. Success in one part of the country has often been counteracted by failure in another, at all events from a commercial point of view. In spite of widely separated operations spread over a number of years, the chance find of petroleum in a water well at Comodoro Rivadavia in 1907, the impetus this gave to the industry, and the position of that field to-day as the most important in the country—the output averages some 750,000 tons annually—are still the outstanding features of oil exploration in this part of the world. At Comodoro Rivadavia the oil is apparently obtained from Cretaceous beds (Danian and Senonian), in which lenticularity is the dominant factor, though owing to a thick covering of Quaternary deposits and the presence of two unconformities within the Tertiary sequence, the geological structure of the oil-bearing rocks remains doubtful. The oil has a gravity of 0·912, a viscosity (at 15° C.) of 21·15, flash point 22° C., with 77 per cent. distilling over above 300° C. It is thus essentially a fuel oil, and is used as such at Buenos Aires and Bahia Blanca, where most of it is shipped. Other actual and potential oilfields include those of the Province of Neuquen, the Cerro Alquitran and Cacheuta fields of the Province of Mendoza, and the Salta-Jujuy territory bordering Bolivia. Two economically important veins of high grade asphalt occur near the ancient volcano Auca Mahuida; from the analytical details given, this bitumen is remarkably pure, and recalls some of the grahamite successfully mined in the United States. Future prospects of the Argentine as an oil-producing country lie in extending the Comodoro Rivadavia field, and in the more intensive development of fields such as those of Neuquen, where higher grade oils are obtainable and from which South American markets must eventually be fed.

Selenium Cells and X-rays of Various Wave-lengths.—Dr. H. Küstner describes experiments in which he has compared the action of X-rays on selenium cells, and on ionisation chambers of greatly differing dimensions, in the *Zeitschrift für Physik* of September 2. It is not possible to use fully monochromatic X-rays, as the selenium cell is not sufficiently sensitive; but copper filters of varying thickness were employed with different voltages on the X-ray tube, so that different degrees of hardness were obtained. The average wave-length varied from 0·119 Å to 0·473 Å. The larger of the two carbon ionisation chambers employed was 25·5 cm. high and 6·4 cm. in diameter, while the smaller "thimble" chamber was 21 mm. high and 14 mm. diameter. The ratio of the reading with the selenium cell, and that with the large chamber, showed a maximum at about 0·22 Å, and only half this maximum value was observed at about 0·12 Å and 0·4 Å. This behaviour cannot be related to an absorption spring in selenium, since the shortest wave-length of an absorption band head, that of the K series, is near 0·979 Å. The fact that the ratio between the values obtained with the two ionisation chambers varies with the hardness excludes a suggestion that the X-rays do not produce the full amount of ionisation, being absorbed by the walls of the chamber. An attempt is made to explain the phenomenon as being due to the difference between the scattering and pure absorption effects in air and in selenium. Although a quantitative treatment is not at present possible, a qualitative explanation is obtained.

Atomic Rays from Heated Salts.—In the *Annalen der Physik* for October, Dr. G. C. Schmidt describes experiments in which a platinum wire is coated with various salts, and heated electrically *in vacuo*. The wire is surrounded by a wire gauze cylinder which is connected to an electrometer, and the sides of the containing glass cylinder are lined with earthed wire gauze. Simple solid or fluid substances, which at a given temperature give out positive or negative ions, or both, conduct electrolytically at that temperature; if they give out electrons they conduct metallically. Salts in which the positive ions are alone mobile send out positive ions only, and similarly for negative ions; while, if the mobility of one kind of ion is greater than that of the other, the first is given out faster than the second at the temperature in question. Complexes such as Cd_nI_{2n} are formed in the solid salt, which disintegrate into $Cd_{n-1}I_{2n}$ and Cd^+. When iodine and bromine, which form complex salts, are present, they break up the large aggregates such as Cd_nI_{2n}, and so the number of ions increases and more are given off. At the same time a badly conducting layer forms on the wire and in the end the current falls. Measurements of the ratio e/m show that the salts of various metals send out positively charged metal atoms; the values of m thus

obtained are as follows—Cd 54-58·4, Cu 31·1-32·7, Zn 32·4, Pb 108·4, Ca 20·5; these are approximately half the atomic weights, since each atom carries the charge $2e$ of two electrons.

ELECTRICITY FOR AUXILIARY POWER ON SHIPS.—In a paper read to the Institution of Engineers and Shipbuilders in Scotland on November 18, by Mr. Gilbert Austin, a new system of electric driving which will be specially useful for driving the capstans, steering gear, pumps, fans, etc., used on board ship is described. The drawback to the ordinary shunt motor used on a constant voltage system is that it is practically a constant speed machine, and if it is pulled up there is a risk of the armature being burned out. The author has devised an ingenious system in which the current through the armature is independent of the speed, and the voltage of the constant current generator varies with the load. He shows how readily it can be applied to various kinds of ships. In a passenger liner, for example, there are three entirely independent circuits each actuated by its own constant current generator, which is driven by a steam turbine. At times of light load any one of the units may be used to supply the whole ship. Some startling statements were made about the cost of running steam auxiliaries. A 15-knot turbine vessel was found to be burning too much coal. It was found by tests that the main turbines took 75 tons of coal per day, whilst the various auxiliaries were responsible for 30 tons. The steam steering gear alone took 7 tons of coal per day. Assuming 250 days per annum at sea, and that coal costs 30*s.* per ton, the fuel cost alone for that particular steering gear amounts to 2625*l.* per annum. The author says that this steam steering gear could have been worked by a 40 horse-power electric motor at an annual cost of about 40*l.* Thus electric driving would effect a saving of 2585*l.* per annum for the steering gear alone. In another case, the loss of steam from 20 leaky joints in long lengths of steam piping was estimated to waste coal at the rate of 440*l.* per annum.

OLIVE OIL.—The *Chemical Trade Journal* for Oct. 24 prints a review of the olive-oil industry. Two varieties of olive tree are known, but only the cultivated thornless type, which exists in forty-five subvarieties, is used for oil-production; it is cultivated chiefly in Asia, Australia, South Africa, the Western States of America below latitude 35°, and, from the very earliest times, in Mediterranean countries. Spain and Italy are the two largest olive oil producing countries. The ripe fruit yields a sweet pale yellow oil if pressed immediately after gathering; stored ripe fruit gives an inferior colourless oil and unripe fruit a green, bitter oil. The extraction process is described in some detail; the physical and chemical properties are tabulated. The oil appears to consist of 70 per cent. tri-olein and 28 per cent. of tri-palmitin and tri-stearin, together with a small quantity of linolein and arachin. The applications of the oil and of the by-products of manufacture are discussed in detail, as also is adulteration. Its chief uses are for human consumption and in the manufacture of artificial leather and of soap.

THE ELECTRIC MOMENTS OF MOLECULES.—In the October number of the Journal of the American Chemical Society, C. P. Smyth shows how the electric moment of a molecule can be calculated from measurements of indices of refraction, dielectric constants, etc. These calculated moments are much smaller than those deduced from the hypothetical molecular structure based on G. N. Lewis's theory, and the conclusion is drawn that the charges shift under the forces of attraction and repulsion within the molecule, the discrepancy depending on the ease of displacement of the electrons. The electric moments of a series of alcohols, ethers, and analogous sulphur compounds vary from 1 to 2 times 10^{-18}; the value for water is $1{\cdot}98 \times 10^{-18}$, whereas the value deduced from the atomic structure model is $5{\cdot}51 \times 10^{-18}$. The forces required to displace an electron through unit distance are calculated in dynes $\times 10^{-6}$; water, 1·24; ammonia, 0·84; methane, 0·71; hydrogen sulphide, 0·51; and these are regarded as indicating the order of magnitude of the mobilities of the electrons in the molecules.

FLUORINE AND HYDROGEN FLUORIDE.—The preparation of fluorine by the electrolysis of fused acid potassium fluoride in a copper apparatus with a copper diaphragm and graphite anode is described by J. Simons in the October issue of the Journal of the American Chemical Society. Fluorine was obtained at the rate of 4 litres per hour, and the apparatus could be run for 20 to 30 hours. The same author also describes the preparation of anhydrous hydrofluoric acid, and measurements of its freezing-point ($-83°$ C.) and vapour pressure. Anhydrous potassium hydrogen fluoride was heated in a heavy copper retort; the vapour was passed through a tube packed with copper wire to remove salt spray, and condensed in a gold-plated copper cylinder. The relationship between pressure and temperature was found to be reproduced by the equation

$$\log P(\text{mm.}) = -1315/T + 7{\cdot}37.$$

Measurements of the vapour density of hydrofluoric acid, made by Simons and Hildebrand, are described in the same journal. Nitrogen was bubbled through the liquid acid, and the hydrofluoric acid vapour carried off was absorbed in weighed copper tubes containing sodium fluoride. From the known vapour density and the weight carried off, the density of the gas could be calculated. At the low temperatures used (15-19° C.) the molecular complexity exceeded H_4F_4. The results could be correlated with the vapour density measurements of Thorpe and Hambly at higher temperatures, by assuming that the vapour contains an equilibrium mixture of HF and H_6F_6 and a heat of association of 6670 cal. per mole of HF.

STAINLESS STEEL.—At an informal meeting of the Junior Institution of Engineers on November 21, Mr. J. G. Hopcraft discussed this material. The special properties of stainless steel are inherent and not merely superficial. The properties of withstanding heat and corrosion and remaining bright are produced immediately after tempering and removal of the scale, with polishing if necessary. The fact that the steel has to be heat-treated after being worked imposes a limitation on the size of job which can be undertaken, so that the production of large girders, for example, is not a commercial proposition at the present time. Stainless steel has good heat-resisting qualities and will not scale up to about 800° C., the effect on the surface being confined to colour effect only. The removal of scale from the inside of long tubes and similar inaccessible positions is difficult. Stainless steel cannot be expected to machine like mild steel, but with the right degree of hardness and a little experience in the use of the tools for the particular job, the turning and screwing, etc., of the metal can be carried out without much difficulty. A new stainless steel combining a high degree of resistance to corrosion with extreme malleability has recently been brought out under the name of "Stabrite." This metal can be produced in sheets for cold-pressed articles which require no further heat treatment. It cannot be hardened, but can be welded, soldered, and brazed fairly easily.

Science in South Africa.

THE twenty-second annual meeting of the South African Association for the Advancement of Science was held at Cape Town on July 7-12, under the presidency of Prof. J. A. Wilkinson, professor of chemistry in the University of the Witwatersrand, Johannesburg. The meeting was well attended, and more than 80 papers were read. Joint meetings of sections were held for a symposium on veld-burning and for the paper by Prof. H. B. Fantham on "Heredity in Man: its importance both biologically and educationally." There were various visits to places of scientific and historic interest in the neighbourhood, and a popular lecture was delivered by H.M. Astronomer at the Cape, Mr. H. Spencer Jones, on "Wireless Messages from the Stars." A scientific conversazione was arranged by the Royal Society of South Africa, and there was a reception by the Consul-General for Belgium.

The president of the Association, Prof. J. A. Wilkinson, gave as his presidential address, "A Review of some Developments in Chemistry during this Century." Commencing with a historical résumé, a synopsis was then given of progress in knowledge of the zero valency elements, radium developments, cathode rays, positive rays, atomic structure, X-ray spectra, newer work on isotopes, the configuration of the atom, X-ray crystal analysis, colloid chemistry and its developments, Werner's co-ordination theory, hydrogen-ion concentrations, and the theory of solutions. Progress in organic and inorganic analysis was noted, and the methods of soil analysis were outlined. The address concluded with a statement of the needs of research and an appeal for such research.

The presidential address to Section A was delivered by Dr. J. K. E. Halm, on "The Luminosities of the Stars." The history of progress in the several branches of astronomy was traced. The visual and photographic methods of obtaining photometrically correct magnitudes were discussed, and the practical applications of Planck's formula to the distribution of energy in stellar spectra were outlined. Methods of determining distances of stars were noted, and some new results recently obtained at the Cape Observatory in connexion with masses of the stars were outlined. The need of adequate equipment of observatories was urged.

Dr. A. L. du Toit, president of Section B, took as his subject, "The Contribution of South Africa to the Principles of Geology," in which he described the advances made, indicated the bearing of such discoveries in advancing geological theory, and suggested lines for future research. In mineralogy, reference was made to crocodilite and African "jade." The different origins of several kinds of asbestos in the Union, stanniferous ores in the Bushveld tin fields, gold-bearing conglomerates and kimberlite were discussed, and the Bushveld igneous complex of the Transvaal indicated as a field for research. The history of past glaciations in South Africa, and evidence of at least four past glaciations, were presented. The evidence for the existence of Gondwanaland and the hypothesis of continental disruption were discussed. The palæontological vertebrate assemblage of South Africa and its development were noted, as was the well-known Glossopteris flora. The address concluded with an appeal for more attention to field geology.

"Kirstenbosch, South African Botany and Nature Reserves," was the subject of the presidential address to Section C, given by Prof. R. H. Compton, who directed attention to the need for greater output of research, and for developing on national rather than on local lines. The creation of the National Botanic Gardens at Kirstenbosch, their history, manifold botanical possibilities due to situation, rainfall, variety of soil and many types of vegetation were described. Substations are projected, one of which, the Karroo garden, has materialised. The wide scope of the intended activities of the National Gardens was outlined and the need of pure research, in contrast to applied work, was emphasised. Kirstenbosch is also a sanctuary for the native flora and fauna of South Africa. The importance of the preservation of mountain catchment areas by an adequate covering of natural vegetation, the prevention of unnecessary veld-burning, the protection of the natural flora, and its preservation under natural conditions were urged.

Prof. E. H. Cluver dealt with "Some Applications of Physiology to Industrial Hygiene" in his presidential address to Section D. It was pointed out that all improvements directed towards improving health also increase efficiency. Developments in work on industrial fatigue, tests for the assessment of fatigue, arrangement of work periods, rhythmic movements, work postures, etc., were discussed. The importance of atmospheric conditions, such as heat and moisture, particularly in South Africa, in the mines and in factories, was emphasised. Dusty conditions, particularly silicosis, were considered. Dietetics were discussed from the point of view of under-development, correct feeding, and adequate supply of vitamins. It was pointed out that stunted growth and low resistance to pathogenic organisms are accompanied by industrial discontent, and physical inefficiency by inadequate output.

The presidential address to Section E, "The Education of the Native," was delivered by Mr. W. G. Bennie, who has had thirty years' experience of native education in the Cape Province. The historical landmarks in native education were first outlined, and the nature or scope of native education discussed. In primary schools a fairly liberal course with a strong industrial bias was recommended, the native language being the medium of instruction in early life and one of the official languages later. Instruction in physiology and hygiene and some form of handwork is essential. Secondary school work should resemble that for Europeans, suitable options being provided. Agricultural training is of great importance. A sympathetic attitude towards native education was urged, since the raising of the native is necessary for economic development, for the maintenance of our own civilisation, and from motives of justice.

The Chief Archivist of the Union, Mr. Graham Botha, delivered his presidential address to Section F on "The Public Archives—their Value to Scientific Research." After dealing with the widespread interest of the Archives, archive administration and availability, the Archives as a great storehouse of materials for research was dealt with at some length. The historian can find documents for reconstructing the history of the race and for studies in political and social evolution; the political economist can obtain materials relating to wages, land tenure, currency, commerce, development of resources; agricultural progress can be traced; sociologists can study to advantage the organisation and development of society in all its grades in South Africa. Documents on agrarian practices, plant life and forest reports are not only of intrinsic interest but also of economic importance. The Archives thus can provide abundance of material of great diversity for investigators in numerous fields of knowledge.

It is only possible to notice briefly some of the interesting papers read before the various sections.

In Section A, Dr. J. D. Schonken gave a paper on desiccation and how to measure it, defining desiccation, exsiccation, and siccation. He considers that a growing irregularity of rainfall provides a more trustworthy index of desiccation than the measurement of rainfall in inches. Dr. J. S. van der Lingen contributed a paper on the planetesimal hypothesis and dealt with uniform belts of planetesimals and equatorial accelerations. Dr. B. F. J. Schonland gave a paper on the scattering of the cathode rays, considering that the law of force in an encounter between an electron and an atomic nucleus appears to be that of the inverse square.

In Section B, Dr. B. de C. Marchand read a paper on the origin of black turf soils in the Transvaal. These are really clays, derivatives of plagioclase, and not particularly rich in organic matter. Mr. C. W. van der Merwe dealt with the formation of soil from diabase in the central Transvaal, the weathering being mainly due to chemical decomposition. Prof. G. H. Stanley reviewed metallurgical progress in the Transvaal during the decade 1914–1924. Mr. T. Leslie discussed the huge Transvaal formation of dolomite, which is very suitable for fluxes. Dr. J. J. Theron and Mr. J. V. Cutler gave a paper on the function of nicotine in tobacco, which their investigations show to be a storage product and not waste. Mr. Cutler also gave an account of the growth, ash content and constituents, and nicotine content of tobacco grown on experimental fertiliser plots at the Rustenburg Cotton and Tobacco Station. Mr. Steenkamp described the chemical composition of the latex of a Euphorbia. Dr. Theron wrote on the reaction of some Transvaal soils. Messrs. A. J. Pelling and J. B. Robertson further discussed the reciprocal salt-pair formed by sodium chloride and calcium nitrate. Studies on the thiazoles were contributed by Dr. J. L. B. Smith with Messrs. E. H. Flack and A. R. Inggs. Mr. O. G. Backeberg gave a paper on the theory of indicators. Mr. W. Torrance described his studies on metamorphic mudstones, and Dr. F. Nopcsa made a palæontological contribution on the systematic position of Saurosternon and Tangasaurus.

In Section C, Dr. R. Marloth gave a paper on the determination of acidity of soils. He considers Truog's test convenient and sufficiently accurate for the farmer. Prof. C. E. Bremekamp made a contribution on hydrotropism and thigmotropism of roots, and Prof. R. S. Adamson described some new cases of secondary growth in monocotyledons. The seaweeds of the Cape Peninsula and their distribution were discussed by Mrs. M. R. Levyns, the Atlantic and Indian Ocean seaweeds being contrasted. Notes on the aquatic flora of South Africa were presented by Miss E. Stephens. Mr. A. Stead contributed a paper on Saaidam terraces in the Karroo, a method valuable for securing an underground water-supply. Dr. J. S. van der Lingen gave three papers on plant pigments, including those of *Bacillus pyocyaneus*, which he has examined spectroscopically. Dr. W. F. Barker summarised his results on the function of the chloroplasts in carbon dioxide assimilation. Dr. T. Sim gave further notes on mosses from the south-west part of South Africa, and Prof. P. A. van der Bijl continued his descriptions of South African Polyporeæ. Mr. Pont contributed a paper on osmotic pressure in correlation with growth form and habitat. Mr. J. Phillips gave an interesting paper on the biology, ecology, and sylviculture of a valuable indigenous timber tree, *Ocotea bullata*, known as "stinkwood."

The symposium on veld-burning was opened by Dr. R. Marloth, who dealt in general with the problem, illustrating from occurrences in the South-west Cape, where thick evergreen scrub has been replaced by fire-resisting bulbs as a result of veld-burning, the run-off being greatly increased. Capture of water from the south-east cloud by mountain vegetation was urged. Mrs. M. R. Levyns spoke of the effect of veld fires on two contrasted areas in the Cape Peninsula. Mr. Pillans described the destruction of indigenous vegetation in the Cape and condemned veld-burning. Mr. Graham Botha contributed an historical account of the practice, originally derived from the Hottentots.

In Section D, Mr. A. D. Stammers dealt with the effect of altitude on health and longevity; from physiological experiments and statistical data he concludes that if certain minor precautions are observed, detrimental effects will not accrue from long residence at altitudes of 4000 to 6000 feet. Dr. Annie Porter gave an account of five kinds of insect larvæ observed by her in man in South Africa. Prof. R. W. M. Mettam described an ox liver possessing accessory lobes and so being more equine than bovine in character, and also described the greatly enlarged condition of the petrous temporal bone of a calf. Prof. H. B. Fantham gave an account of his further researches on parasitic Protozoa, and described *inter alia* a new Entamœba from a duck, a new Herpetomonas from the larva of Eristalis, and several new Trichodinas. Prof. Fantham also summarised the observations on various protozoal and helminthic parasites from South African Amphibia that have been investigated by Miss C. Weinbrenn and himself, and presented a further report, in collaboration with Miss N. F. Paterson, of their researches on the protozoal fauna of certain South African soils. The distribution of the soil Protozoa differs in the coastal belt, the Karroo belt, and the High Veld. It also varies in soils from False and Table Bays, which are adjacent. More work on seasonal variation in soil Protozoa and a preliminary account of the effect on them of veld-burning were also recorded. Mr. H. H. Curson presented a paper on the causal agents of nagana, showing that *Trypanosoma brucei*, *T. vivax*, and *T. congolense* are all associated with this condition in Zululand. Mr. H. H. Curson and Mr. J. M. Hugo discussed the preservation of game in South Africa, giving details of the various game reserves and measures for game preservation. Dr. C. S. Grobbelaar gave an account of his interpretation of the blood vascular system of *Xenopus lævis*. Dr. M. M. Prates sent a note on the fusiform bacillus-spirochæte association found among natives in Portuguese East Africa. Mr. J. Hewitt discussed the irreversibility of evolution, giving examples, particularly among spiders, tending to show that reversible evolution is possible by loss of mutations. Prof. J. E. Duerden and Miss M. Ritchie traced the development of the merino wool fibres from their first appearance to the birth of the lamb. Prof. Duerden and Miss G. Brock described the structure of the lining of the gizzard of the ostrich. A joint meeting was held with Sections E and F for a paper by Prof. H. B. Fantham on heredity in man, its importance both biologically and educationally. In this an account was given of various heritable traits, physical, mental, and moral, shown in man, both normal and abnormal characteristics being considered. The interaction of eugenics and euthenics was noted. Sociological applications were made, and suggestions put forward for educational betterment.

In Section E, Miss D. Earthy described various body markings employed more particularly by the VaChopi and VaLenge of Portuguese East Africa. Mr. A. J. H. Goodwin dealt with AmaPondo sibs. Col. W. E. Hardy exhibited stone implements col-

lected in the Cape and demonstrated methods of preparing them. Mr. G. D. Laing gave an account of Strandlooper skulls from Zitzikama, showing transition from a short face with light zygomatics to a long face with prominent zygomatics. Prof. R. A. Dart gave a paper on the Rooiberg cranium, which is probably not that of an ancient miner, but of a man who used the old mine as a dwelling. Prof. A. Radcliffe Brown gave details of the position of the mother's brother among the Bantu, a proper understanding of which is very necessary in dealing with native peoples. Prof. W. A. Norton and Mr. H. Velaphe presented sixty-eight Sesuto riddles with translations of the same. The science of tonetics and its application to Bantu languages was discussed by Dr. D. M. Beach.

In Section F, Advocate G. T. Morice discussed psycho-analysis and criminals, criticising various methods and certain new books. He considers Freudian psycho-analysis of little use, as it concentrates on the sexual and ignores other instincts. Prof. S. F. Gie gave an account of the economic development of South Africa from 1652 to 1795. Prof. R. D. Nauta gave a reasoned résumé of the moral value of Molière's works. The conception of intelligence was dealt with by Prof. R. W. Wilcocks. Much interest attached to a paper by Mr. C. S. Richards on the monetary history of South Africa since union, in which the currency problem and inflation of currency were dealt with, and a return to the gold standard advocated. Of much historic interest also was Miss M. L. Hodgson's paper on the Hottentot question in South Africa down to 1828. Prof. E. H. Brookes discussed the changes in native economic life in South Africa due to European influence and changes in Europeans due to native influences. He advocates economic differentiation and native development in agriculture and native industries, with no detachment of their natural leaders from the bulk of the Bantu. Mrs. Mabel Palmer gave an account of a South African Whitley Council as shown in the organisation of the printing industry. Rev. R. Balmforth pleaded for a more fully representative international authority than the present League of Nations.

As a result of Dr. Fantham's paper, the Eugenics and Genetics Committee of the Association has renewed its activities.

The next anual meeting of the Association will be held at Oudtshorn, under the presidency of General J. C. Smuts, in July 1925.

H. B. FANTHAM.

Sex Determination.

MANKIND has always been intrigued by the problem of what are the factors that determine sex, but it is only comparatively recently that a real light has been thrown upon this subject. The influence of the sex glands upon certain characteristics of the body has, it is true, been known for many centuries, as witnessed by the effects of castration, but the mechanism by which these changes are produced was obscure. With the discovery by Oliver and Schäfer in 1894 of the effects of suprarenal extracts upon blood pressure, a mechanism by which one part of the body may influence another (other than that involved in the intervention of the nervous system) was suggested, and experiments have shown that the action which the sex glands exert upon the body generally must be due to a substance or substances—"hormones" in fact, or chemical messengers—circulating in the blood stream. Thus removal of the testes or ovaries from their normal position to another part of the body produces no alteration of bodily appearance, although all nervous connexions must necessarily have been severed. Complete extirpation of both glands, however, leads to disappearance of those characters which are correlated with sex and are known as the secondary sex characteristics.

It is interesting to note that these characters vary considerably according to the species: thus the antlers in certain species of deer are present in the male sex only; the combs and spurs of cocks are peculiar to the male; in male frogs in the breeding season a clasping pad is developed on the thumbs. The external differences, however, between the sexes are especially well marked in birds, where the two sexes usually possess a very different plumage. For this reason, perhaps, those rare cases in which the creature during its lifetime changes its sex have been more frequently described in birds: these "freaks" have always excited much curiosity. In a recent paper in *Science Progress* (October 1924) F. W. Rogers Brambell describes some examples of this transformation. The change is always of a female into a male, and *post mortem* examination discloses the presence of testicular tissue as well as or without ovarian tissue: at times the latter is mostly degenerated. The change is therefore due to the development of a sex gland of the opposite sex; but the transformation is usually incomplete, some of the female characteristics remaining unchanged.

Now after simple removal of the sex glands from an animal the characteristics of the opposite sex do *not* usually develop; the change in appearance is towards a neutral type which, according to the species, may be either nearer to the male as in birds or to the female as in mammals. It is, however, certain that the actual appearance of the opposite sex depends on the development of the appropriate sex gland. Does this imply that every organism in species with separate sexes contains within itself the factors upon which the sexes ultimately depend? Probably this does not occur normally, the sex of the individual being determined at conception, possibly by the particular arrangement of the chromosomes in the ovum and spermatozoon which unite in fertilisation. The sex-determining chromosomes pass into the sex glands and thus influence the development of the somatic cells along the lines of the particular sex involved. In certain rare cases, however, of hermaphroditism or sex reversal the sex chromosomes of *both* sexes must be present, and the result is either a mixture of the two, or one predominates either completely or for a time.

This view is borne out also by the fact mentioned above that simple removal of the sex glands does not produce the characters of the opposite sex: on the other hand, the somatic cells are capable of being influenced by the secretions of *either* gland, and after removal of the normal glands, grafting of the glands of the opposite sex from an animal of the same species leads to the development of the characteristics of the grafted sex. The factors which produce any particular arrangement of the chromosomes in the ovum or spermatozoon and so lead to the appearance of the corresponding sex are not yet completely elucidated: it is, however, suggestive that in pigeons and doves, Riddle found a predominance of males amongst the offspring when the parents were the most vigorous, early in the breeding season. One factor which influences the constitution of the spermatozoon or ovum is therefore the general metabolic condition of the parent. Research along these lines may lead in the future to knowledge which will enable mankind so to arrange the conditions as to produce, with a fair amount of certainty, an offspring of the sex desired.

The Ramsay Memorial Laboratory, University College, London.

THE new Chemical Engineering Laboratory at University College, London, founded as a memorial to the late Sir William Ramsay, was opened on November 12 by H.R.H. Prince Arthur of Connaught, accompanied by Princess Arthur. There was a large gathering, including Lady Ramsay and representatives of university, professional, and industrial circles.

Sir Robert Robertson from the chair emphasised the need, felt especially during the War, for men trained in the development of chemical operations to the industrial scale. He laid stress on the necessity of thorough preliminary training in chemistry, physics, and mathematics, and also on the need for whole-hearted co-operation between the industries themselves and the new department, in providing facilities for students to extend their training to include actual works practice and the investigation of problems on a manufacturing scale. He stated that he noticed recently in America that it is possible for the universities to maintain a small colony of post-graduate students at the factories, working on fundamental plant problems, and that this arrangement seems to work to the utmost advantage of both students and manufacturers. He urged chemical manufacturers in Great Britain to consider the possibility of similar co-operation.

Prince Arthur of Connaught, in declaring the Laboratory open, sketched the history of the Ramsay Memorial Scheme, which has now been carried to completion. The new Laboratories—which are temporary—have been reconstructed and equipped under the guidance of Prof. E. C. Williams. In addition to the funds handed over by the Ramsay Memorial Trustees, the Laboratory has received generous support from many of the great British chemical firms, which, by subscriptions for a period of five years, have ensured a minimum income of 1400*l*. Further support is still needed to enable the Laboratory to rise to its full powers of usefulness to industry.

Mr. W. J. U. Woolcock, president of the Society of Chemical Industry, said that although there has, in the past, been some doubt as to the value of the chemical engineer, he looked forward to this pioneer laboratory, as a result of the course of studies which has been framed, sending out men who will play a great part in British chemical industry. He noticed with great satisfaction that Prof. Williams had laid stress on the planning of the large scale operations with special regard to the underlying chemical and physical phenomena involved, as well as on the actual design and operation of the plant. He foresaw the Laboratory becoming a centre to which chemical manufacturers would send their fundamental problems for solution, and although Great Britain is an old and conservative country, in which tradition dies hard, he appealed to manufacturers to bear in mind the possibility of still further co-operation along the lines indicated by Sir Robert Robertson.

Prof. E. C. Williams, in describing the scope and facilities of the Laboratory, said that the chemical industries require men of the same high scientific imagination and experimental skill as have done such great work in the pure sciences, but they must be trained to apply these gifts to the problems and plant operations of chemical industry. In the Ramsay Laboratory, men would be encouraged to develop processes from the test-tube scale to the industrial scale, and themselves to work out the whole of the data necessary for efficient operation on a commercial scale. Chemical engineering is essentially a quantitative science. Provision is made in the Laboratory for carrying forward investigations to the semi-industrial scale; a special laboratory has been built for this purpose, in which students can erect any plant they desire to their own designs and to meet their own special requirements.

A vote of thanks to His Royal Highness was moved by Sir John Rose Bradford and seconded by Mr. Roscoe Brunner.

After the ceremony, the Laboratory was thrown open for inspection. In addition to chemical and physical laboratories, there are provided a drawing office, mechanics shop, which is available for the use of students, and an industrial laboratory. The guiding principle in the design of the Laboratory has been flexibility. This is particularly apparent in the industrial or semi-large scale laboratory, where structures, services (including steam, gas, water, power, electricity, vacuum, and compressed air), and equipment are designed to give the greatest facility in the erection and operation of any desired experimental plant. The Laboratory is already well equipped with plant planned for quantitative investigation rather than for the illustration of industrial practice, it being felt that the latter can only be satisfactorily obtained at an actual factory.

Innermost Asia: its Geography as a Factor in History.

SIR AUREL STEIN delivered the first "Asia Lecture" before the Royal Geographical Society on November 3. He chose for his subject an account of his three expeditions to the Tarim Basin in Chinese Turkestan, which he undertook in the years 1900–1, 1906–8, and 1913–15. Sir Aurel has long held a foremost position as an archæologist and explorer. We well remember, many years ago, his interesting investigations into the identity of the site of Mount Aornus, described by the Greek historians, somewhere to the north of Attock, which Alexander the Great besieged on his way to India. Since then he has gone much farther afield, and his chief work has been in Central Asia.

The scene of these explorations lies in the great drainageless basins situated between the Tien-Shan, or "Celestial Mountains," on the north, and the Kun-lun ranges to the south which separate them from Tibet. To the west it abuts on the great mountain masses of the Pamirs, and on the east is bounded by the Nan-Shan forming the watershed towards the Pacific Ocean. This vast area is some 1500 miles long from east to west, and up to 600 miles wide from north to south. But "ground capable of settled life is strictly limited to strings of oases and only a few of them in the extreme east and west offer enough arable soil to support a population of some size. The rest of the area is occupied by huge stretches of desert . . . almost everywhere devoid of water."

This desert differs from the deserts of Arabia and South Africa, where whole tribes move about, sure to find grazing for their flocks, at least at certain seasons of the year. Such is not the case in the deserts of the Tarim Basin, where "the absence of moisture bans not only human existence, but practically also all animal and plant life," and what life there is, round the scattered oases, is entirely de-

pendent on irrigation derived from the water of glacier-fed rivers, which, if not artificially caught, rapidly disappears in the sand. This absence of atmospheric moisture is due to the immense distance which separates this region from the sea, and the high mountains which intervene on all sides.

The importance of the Tarim Basin lies in the fact that it was in the direct line of communication which once formed the great trade route between China and the West. Two thousand years ago it seems to have been the only means of interchange of commerce between the Far East and the West. Not only does the shortest route lie along it, but also the way to the north was barred by the presence of the fierce and warlike Huns and the Tien Shan Range, while to the south the snow-clad mountains of Tibet and the Himalayas formed an impenetrable barrier. Formidable as the passage of such a desert must have been, it appears to have presented less difficulties to the Chinese than were likely to be encountered on any alternative route. These circumstances accounted for the control China found it necessary to assume over this far-extended line, which eventually reached to the Pamirs. This was at first of a political nature, but ended in complete military occupation lasting for a thousand years. Sir Aurel Stein has been able to trace over a long distance the remains of the old *Limes*, or defensive wall, erected at the end of the second century B.C., no doubt the ancient representative of our modern line of block-houses.

The reasons for the abandonment of such a route as this, and the evacuation of the former inhabitants, give rise to interesting speculation. Was it due to an alteration of climate bringing about excessive desiccation, or to some other cause? From the high state of preservation of records, and other materials, discovered by Sir Aurel, it would appear that the climate has not altered and is much the same now as it was 2000 years ago, for such friable objects as were found could only stand the test of time in an extremely arid climate. If, then, the occupation of this area was independent of climate, it must have been dependent on irrigation, which in its turn was dependent on water derived from glacier-fed rivers.

The lecturer discovered several abandoned sites of human habitation which had been maintained by irrigation, but are now far distant from the terminal point of the river which formerly supplied them with water. This seems to show, as originally suggested by Sir Sidney Burrard, that the evacuation of this area was due to the diminution of water in the rivers and not to an alteration of climate, of which there is no evidence. The glaciers, probably the remains of a former ice-age, are known to be shrinking, with the consequent decrease of the water supply, which probably accounted for the abandonment of this important commercial highway. But while this seems to afford an explanation, it is not safe to rely entirely on it, as there is always the human element to be taken into account, and that is not so easy to gauge. The way in which the Chinese have held this region, throughout the long years of varied history, is a remarkable testimony to their tenacity of purpose. On more than one occasion it has been lost, generally on account of internal dissensions, only to be regained in more settled times, and is held down to the present day.

It is to be hoped that at some future time Sir Aurel Stein will give us some details of the contents of the documents he has found, and of other objects of interest. We may add that he was accompanied on his expeditions by surveyors of the Indian Survey, and that a series of maps on a scale of 1/500,000, and 1 inch to 4 miles, have been produced by that department as the result of his surveys. H. L. C.

Tropical Medicine in the Southern United States.

THE recent Conference on Tropical Problems at Kingston, Jamaica, has served to direct attention to the enormous interest which is taken at the present time in tropical medicine and allied sciences in the United States. This movement may be said to have started some thirty years ago when the States had to take control of the Philippine and Cuba Islands after the Spanish War; it became greater when it was decided to open the Panama Canal. The building of the canal was rendered possible by the genius of Gorgas, who applied in a practical way the discoveries of Ross and Manson. The scourges of yellow fever and malaria which had caused the complete failure of the French effort were successfully combated, and the canal was built.

A very important feature of the moment is that private concerns and corporations with estates and financial interests in the tropical zone are taking great interest in tropical medical problems. Some of these concerns have complete medical services of their own. The United States Fruit Company, for example, has a tropical medical service admirably organised, with branches in several Central American countries, Guatemala, Costa Rica, Honduras, etc. At the head of each branch or division there is a principal medical officer with an adequate medical and nursing staff in each division. The Company has built one of several up-to-date hospitals with splendid laboratories, X-ray departments, etc. Some of these hospitals are magnificent, and would adorn any big European or American city.

Several United States universities, as, for example, Harvard, established departments of tropical medicine some years ago. Funds have been collected now to found a large and up-to-date tropical school at New Orleans, and to institute a professorship of tropical medicine at the University of that city.

New Orleans certainly seems to be from every point of view the ideal place for such a school; it is in one of the most southern parts of the States (Louisiana), and tropical diseases are far from scarce there; yellow fever used to be a scourge in Louisiana and other southern United States, and malaria is still common. It has intimate trade relations with Cuba, Mexico, and Central and Southern America. It has the most famous university (Tulane) in the south, and modern progressive scientific institutes.

The authorities of Tulane University have offered the university professorship and the directorship of the new school to Dr. Aldo Castellani, lecturer at the London School of Tropical Medicine and Director of Tropical Medicine at the Ross Institute. Dr. Castellani is known by his discoveries in connexion with sleeping sickness, yaws, and several other tropical diseases. It may also be remembered that it was Dr. Castellani who, some years before the War, devised and prepared the combined typhoid + paratyphoid, and the typhoid + paratyphoid + cholera vaccines which, after much discussion, were generally adopted by all the allied armies, instead of the simple typhoid vaccination. He has written jointly with Dr. Albert J. Chalmers a standard text-book on tropical medicine, which has run already into three editions.

The Cinematograph in Anthropology.

AT the Royal Anthropological Institute, on November 18, Capt. M. W. Hilton-Simpson showed a cinematograph film of native life in the Algerian Hills. Last winter, when they commenced their sixth season of ethnological research among the Shawiya tribes of the Aures Hills in S.E. Algeria, Capt. and Mrs. M. W. Hilton-Simpson were accompanied by Mr. J. A. Haessler, who is beginning to compile a "library" of cinema films destined to illustrate the ethnography of primitive peoples. He secured a series of pictures among the Shawiya, from which Capt. Hilton-Simpson and he have prepared a film which shows how arts, crafts, and customs, when once they have penetrated to the remote valleys of the Libyan hills, have persisted there unchanged until this day.

The film begins by illustrating the inaccessibility of the inner valleys of the Aures Massif. It shows cave dwellings, palæolithic in their simplicity, still inhabited by the Shawiya (Berber) tribes; and it traces the growth of the cave dwelling to the stone-built Shawiya hut. Views of hamlets of the Aures demonstrate how the villages can have altered scarcely at all since the time of Jugurtha as described by Sallust. The film also shows the occupations of the modern male population; their primitive basketry; the fashioning of wooden door-locks (probably of Roman origin); the chipping out of quern stones; and their methods of husbandry. This last included a complete series of pictures illustrating the use of a "water clock" in connexion with irrigation.

Owing to Mrs. Hilton-Simpson's long acquaintance with the Shawiya women, a full series of photos of the activities of these Mohammedan women has been obtained. The two most complete series of pictures are those representing their weaving and the making of pottery. The former, which appears to date back to early Egyptian times, is shown in all its processes from the shearing of the beast to the finished fabric. The pottery-making, which is done by hand, without the aid of a wheel, appears to be more ancient in its origin even than the weaving.

The final reel of film deals briefly with folk-lore, and illustrates some customs which, it seems certain, constitute a survival of the cult of the great goddess of fertility and the crops, who was worshipped in Libya in early times. The conclusion to be drawn from the film is that, contrary to the belief of the natives themselves and of many European visitors to Algeria, the Shawiya owe but little to the influence of the Roman occupation of the country round; but still keep alive arts, crafts, and customs with which they were probably acquainted long before the fall of Phœnician power in Africa.

University and Educational Intelligence.

CAMBRIDGE.—The Adam Smith Prize has been awarded to G. T. Griffith, Trinity College, for an essay entitled "A discussion of the causes contributing to the increase of the population in England and Wales during the Industrial Revolution, with some inferences drawn from Ireland."

LEEDS.—On grounds of intellectual distinction and of long and meritorious service to the University, the Council has decided to confer the title of emeritus professor upon Dr. J. B. Cohen, who recently retired from the chair of organic chemistry.

Mr. J. W. Baker, senior chemistry master at Barnard Castle Secondary School, has been appointed to a new demonstratorship in organic chemistry.

LONDON.—Dr. F. L. Hopwood has been appointed, as from October 1, 1924, to the University chair of physics tenable at St. Bartholomew's Hospital Medical College. Dr. Hopwood has had considerable experience as a lecturer in physics. During the War he was for three years a research physicist to the Admiralty, and received an award of 1000*l.* for his inventions used by the Service. He is the author of a number of papers in the *Phil. Mag.* (1915–16) and Proc. Phys. Soc. (1921–23).

The title of professor of botany in the University has been conferred on Dr. F. E. Fritsch in respect of the post held by him at East London College. Since 1907 Prof. Fritsch has been head of the Department of Botany at East London College; he has published a number of papers on freshwater Algæ. The title of reader in human embryology in the University has been conferred on Dr. R. J. Gladstone, lecturer and senior demonstrator in anatomy at King's College. The title of emeritus professor of mathematics in the University has been conferred on Dr. M. J. M. Hill, who held the chair of pure mathematics at University College from 1884 to 1923.

Miss Mary Brodrick, a former student of University College, has made a donation for the foundation of an annual prize in geography at that College.

Two University Travelling Scholarships (open to internal and external graduates in all faculties), each of the value of 275*l.* per annum, and three University Post-graduate Studentships (open to internal and external graduates in the faculties of theology, arts, laws, music, and engineering), of the value of 150*l.* per annum, are to be instituted.

The following doctorates have been conferred: D.Sc. (*Zoology*): Mr. H. G. Cannon (Imperial College—Royal College of Science), for a thesis entitled "On the Development of an Estherid Crustacean"; D.Sc. (*Chemistry*): Mr. L. E. Hinkel (King's College), for a thesis on "Reactions in the Hydroaromatic Series resulting in the Formation of Aromatic Compounds."

Dr. G. V. Anrep has been awarded the William Julius Mickle Fellowship for 1925, of the value of 200*l.*, in respect of the work which he has carried out during the past five years in experimental physiology.

Fifteen entrance scholarships and exhibitions are available for award to students entering University College in October 1925. Three of them are tenable in any of the five College faculties: arts, laws, science, engineering, medical sciences, or in the School of Architecture. One is tenable in each of the faculties of science, engineering, three in the faculty of medical sciences, two in the School of Architecture, and one in the School of Librarianship.

A course of five public lectures on "Modern Bacteriological Technique" is to be begun at the Royal College of Surgeons of England on December 11, at 4 o'clock, by Mr. F. W. Twort, Superintendent of the Brown Institution. The succeeding lectures will be given on December 12, 15, 16, and 17. No tickets will be required.

OXFORD.—The Edward Chapman Research Prize, value 20*l.*, will be offered for competition at the commencement of summer term, 1925, to members of Magdalen College who shall have been in residence for a period of two years, for a published piece of original research in natural science. Competing papers or memoirs must reach Mr. R. T. Gunther, Magdalen College, by, at latest, May 1.

THE Scholarship of the Institution of Petroleum Technologists, granted to a student member of the Institution who is completing the petroleum

technology course at the University of Birmingham, has been awarded to Mr. Geoffrey Cotton.

IT is recorded by the *Times* correspondent at Brussels that the foundation-stone of the new buildings of the University of Brussels was laid on November 20 by Prince Leopold. The erection of the new premises has been made possible by financial assistance, amounting to nearly 20,000,000 francs (about 208,300*l.*), given by the Commission for Relief in Belgium and the Educational Foundation, as a result of the good offices of Mr. Hoover. The ceremony coincided with the fiftieth anniversary of the Polytechnic School, and was attended by a number of delegates from British and American universities and technical institutions.

THE Board of Education has issued the following list of successful candidates (in order of merit in each group) to whom awards have been made in the competition for Royal Scholarships and Free Studentships (Science), 1924. GROUP A. ENGINEERING. Number of competitors, 102. *Royal Scholarships*, W. G. Crocker, A. A. Butler, A. W. Morley, J. Donegan, E. W. Packenham, R. A. Yeo, G. W. Mills, W. J. Offord; *Free Studentships*, R. S. Bone, A. S. Crouch. GROUP B. PHYSICS. Number of competitors, 42. *Royal Scholarships*, F. Gill, E. T. D. Offer, D. T. Jones, W. H. Aldous, A. H. Nagle; *Free Studentships*, L. F. Stanley, W. D. Wright, W. Singleton. GROUP C. CHEMISTRY. Number of competitors, 29. *Royal Scholarships*, J. Cantor, A. O. Ball, J. D. Johnson, F. Witt, M. Kamenetsky, P. L. Jones; *Free Studentships*, E. Tanner, J. Anderson, T. Mitchell. GROUP D. BIOLOGY. One candidate. No award. GROUP E. GEOLOGY. Number of competitors, 4. *Royal Scholarship*, F. E. Eames.

THE Rensselaer Polytechnic Institute of Troy, in the state of New York, celebrated last month the hundredth anniversary of its foundation, and Prof. Ray Palmer Baker has contributed to *The Scientific Monthly* an account of some of its services to the cause of science. The first head of this "the oldest institution devoted to science in any English-speaking country" was Amos Eaton, an original genius whose eminence as a naturalist—he has been called the "father of American geology"—was surpassed by his even greater renown as an educator. "He ranged over many subjects—botany, zoology, physics, chemistry, geology, and mineralogy; and in every field he fired the imagination of students who outreached him in knowledge and attainment." He was the first to introduce field work and laboratory practice into the American college, and was the founder of the first popular museum of natural history. His were the first attempts to adapt the results of research to the needs of agriculture. Among other distinguished Rensselaer men were: Ebenezer Emmons, from whose monographs originated the bulletins of the Department of Agriculture; Asa Fitch, the first official entomologist in America, known as the "father of economic entomology"; De Volson Wood, who inaugurated the system of independent colleges for the pure and applied sciences; Henry Augustus Rowland, first professor of physics in Johns Hopkins University, than whom there is no more significant figure in the history of physics in the United States; James Curtis Booth, the most distinguished chemist of his day, who organised at Philadelphia a laboratory on the lines of a miniature factory, the first of its kind; and James Hall, "the founder of American stratigraphy and invertebrate palæontology."

Early Science at the Royal Society.

November 30, 1663. This being the anniversary election-day of a new Council for the year ensuing, the Society met in a solemn manner. The Society proceeded, according to their charter, to the election of the Council and Officers for the year ensuing, observing the orders prescribed for that purpose in their statutes, there being present fifty-seven or fifty-eight fellows.

December 2, 1663. Mr. Boyle moved, that Mr. Povey, Mr. Hoskyns, and others, who could, might bring in their collections of observations concerning springs.

1669. Mr. Hooke produced a picture printed after the expeditious manner of Dr. Wren, who having covered a very thin brass-plate with etching varnish, caused it to be etched upon by a hand careful not to close any letter, in which work the aqua fortis must be so strong, as to corrode the plate quite through: which done, the plate is to be turned and laid upon another thick plate covered all over with printer's ink, to be passed, after the usual manner, through the rolling press.

December 3, 1662. Dr. Power's paper of subterraneous experiments, and observations made of the damps of coal-mines, was read, and registered.

1674. It was resolved, that every member of the present council shall provide an experimental discourse for the Society to be made at some one public meeting within the year, either by himself or some other member of the Society; or to pay forty shillings.

December 4, 1666. Sir Robert Moray proposed, that the council would take into consideration, how the experiments at the public meeting of the society might be best carried on; whether by a continued series of experiments, taking in collateral ones, as they were offered, or by going on in that promiscuous way, which had hitherto obtained.—The earl of Northampton and the lord bishop of Exeter were desired to speak to the duke of Buckingham, that he would accommodate the society with some rooms in York-house for their meetings.

1672. Mr. Oldenburg produced and read a letter from Mr. Lister concerning veins and other curious observables in plants, and particularly of the liableness of all vegetable juices to be frozen, except the milky one. It was ordered to be entered in the Letter-book.

1673. There was present at this meeting the abbé D'Angeau, brother to the marquis of that name, who had attended her royal highness the duchess of York from Paris to London.

December 5, 1667. Mr. Oldenburg produced a great packet of letters and other papers sent to him by Mr. Hevelius. To which were added several relations of other particulars communicated by some learned men at Dantzick, of their own accord, concerning trials made of injecting liquors into human veins, an odd birth of twins, and a suggestion of new materials for telescopical glasses, etc. Of these only that on the trials of injection was read at this meeting. [Oldenburg records that upon hearing the account, a certain physician then present, to Oldenburg's "great grief," was so precipitate as to denounce it. I could not (he says) but take him afterwards aside, and represent to him how he would resent it, if he should communicate upon his own knowledge an unusual experiment to the curious at Dantzick, and they in public brand it with the mark of falsehood: that such expressions in so public a place and in so mixed an assembly would certainly prove very destructive to all philosophical commerce, if the curious abroad should be once informed, how their symbolas were received at the Royal Society.]

Societies and Academies.

LONDON.

Royal Society, November 20.—J. **Barcroft**, M. L. **Anson**, A. E. **Mirsky**, and S. **Oinuma**: The correlation between the spectra of various hæmoglobins and their relative affinities for oxygen and carbon monoxide. Hartridge's reversion spectroscope was used, and it was found that if A be the position of maximum intensity of the α-oxy-hæmoglobin spectral band and B that of CO-hæmoglobin in mammalian blood, and K the equilibrium constant of the equation $CO + HbO_2 \rightleftarrows COHb + O_2$,

$$\text{Log } K = 0{\cdot}05\ (A—B),$$

A and B being in angstrom units. The relation is also true of the recrystallised hæmoglobins. Log K is a measure of the change in free energy involved in the reaction. The value of (A—B), called in the paper "the span," varies from 43 to 56 angstrom units in the mammals observed. The variation in individuals in the same species is very marked, and seems to be due to specificity of the globin portion of the molecule. Brown and Hill's observations on effect of temperature on blood have been treated along similar lines.—H. R. **Hewer**: On certain abnormalities occurring in the pituitary of the frog. Three types of abnormalities are described in the pituitary of the frog: (*a*) Proliferation of cells in the *pars nervosa*; (*b*) formation of non-ciliated cysts in the hypophysial region; (*c*) formation of ciliated cysts in the same region as in (*b*). Probably the non-ciliated and ciliated cysts are similar if not identical in origin. The cilia are therefore incidental, and possibly derived from the epithelium enveloping the anterior lobe.—A. **Howard**: The effect of grass on trees.—J. W. **Pickering** and F. E. **Taylor**: Blood coagulation, anti-coagulants, and hæmolysis. Most substances which inhibit the clotting of blood also inhibit hæmolysis. The anti-coagulants employed were potassium oxalate, sodium citrate, "peptone," leech extract, neutralised thymus, and yeast nucleic acids, novarsenobillon, cobra venom, egg-white, and sugars. A general correspondence between anti-coagulants and substances antilytic to platelets does not exist. The phenomena in protection against hæmolysis and clotting are parallel up to the stage of thrombin formation in the latter process, and experimental evidence shows that the inception of the clotting of blood, like hæmolysis, is essentially the lysis of a colloidal complex, and that both these phenomena are inhibited in a similar manner by certain protective substances. These results support the view that the inauguration of the clotting of blood arises from the disassociation of a protective colloid with the clotting complex of the plasma.—R. J. **Ludford**: The distribution of the cytoplasmic organs in transplantable tumour cells: with special reference to dictyokinesis.—E. **Ponder**: On the balloon-like structure of the mammalian erythrocyte. In the case of the human erythrocyte, the experimentally obtained figures agree in a striking manner with the figures deduced by considering the cell as a balloon-like body with a membrane for which Poisson's ratio is about the same as for most known substances. From this result it may be deduced that Rollett's view of the structure of the erythrocyte is at variance with the facts, and therefore untenable.—V. B. **Wigglesworth**: Uric acid in the Pieridæ: a quantitative study. The wings of the male contain 0·5 mg. and of the female 0·3 mg. of uric acid. This sexual difference is due to the greater size of the wing scales. The pupa of *Pieris brassicæ* contains about 2 mg. of uric acid. This total amount is not changed during development. In the resting pupa most, if not all, of the uric acid is contained in the fat body. Shortly before emergence, some is deposited in the wings and more is transferred to the gut. There is no evidence for a new formation of uric acid during pupal life. The Pieridæ appear to differ from other families in the use to which uric acid is put, and not in the amount of this substance produced.—G. Lindsay **Johnson**: Contributions to the comparative anatomy of the reptilian and the amphibian eye, chiefly based on ophthalmological examination.

Linnean Society, November 6.—E. B. **Poulton**: Mimicry among Fijian butterflies. Of the four species of Euplœa, three had, in the western islands, gained pronounced white marginal patterns in mimicry of the fourth (*helcita*), this last being probably kept constant by fresh invasions from the islands farther west. The ancestral forms of the three species, with reduced patterns, still persisted in east Fiji, and occasional intermediates were found in Taveuni, near to the eastern group, and in the isolated Kandavu. *Helcita*, the model of the other three species in the west, became itself a mimic with reduced pattern in the east, although some reciprocal approach appeared to have taken place in the others, especially the females. *Hypolimnas bolina*, an abundant Nymphaline butterfly with a constant male, had produced, among a wonderful series of female forms, one which was a mimic of the dark eastern Euplœas, and another mimicking the more strongly patterned species of the west. In some islands, especially Viti Levu, many all-female families had been bred; males occur in the island, although far more rarely than females. There was no reason for supposing that these female families were produced parthenogenetically.—Mrs. W. H. **Pearsall** and W. H. **Pearsall**: Phytoplankton of the English lakes. These lakes fall into three groups according to their plankton types: (1) those with green Algæ dominant; (2) those with Dinobryon dominant; (3) those with diatoms and Myxophyceæ dominant. This classification agrees very exactly with their classification according to physical characters, water analyses, and rooted vegetation.—B. M. **Griffiths**: Studies in the phytoplankton of the Lowland Waters of Great Britain: the phytoplankton of Shropshire, Cheshire, and Staffordshire. The natural waters of Shropshire and Cheshire frequently show "water-bloom," due to a prodigious development of blue-green algæ. The algal flora of the district is poor in desmids. One new desmid, a remarkable twisted form, was found in Marbury Mere, and named *Closterium tortum*. In general, these Lowland waters resemble those of the European plain, and differ from the lakes of the British mountain areas.

Aristotelian Society, November 10.—Judge **Dowdall**: What is a society? A society is an interrelation of human action which is complementary, or a number of men regarded as standing to one another in that relation. It is based upon a community, community being defined as an abiding system of mental dispositions such that each member of the society is disposed to perform his appropriate part of the interrelated action as occasion requires. The occasion and the action which it requires are determined partly by institution, an institution being defined as a mental structure determining persons to certain types of conduct in certain types of contingency.

Royal Meteorological Society, November 19.—Sir Gilbert **Walker**: Note on Bjerknes's contribution of 1921 to the mechanics of the general circulation. The object of the note is to elucidate several important

theorems due to Bjerknes; these deal with the slope of surfaces of discontinuity between portions of the atmosphere under various conditions; and so throw light on the general circulation.—W. H. **Dines**: The correlation between pressure and temperature in the upper air, with a suggested explanation. It has been considered that this correlation is due to the fixed relationship between the pressure at the surface, the pressure at any height, and the temperature of the intervening air column. This relationship partly accounts for the high correlation in the troposphere, but fails entirely to account for that in the stratosphere; similarly with regard to the equation for adiabatic change of temperature with change of pressure. If air is forced outwards from the cyclone towards the anticyclone in the upper half of the troposphere, the observed changes of temperature indicated by the correlation coefficient will be produced. This explanation is also valid for the fall of the tropopause in cyclonic regions.

CAMBRIDGE.

Philosophical Society, October 27.—J. T. **Saunders**: The hydrogen ion concentration of the waters of Lake Lucerne. Observations of the P_H of Lake Lucerne during July and August 1923 showed that considerable variation occurred at different depths. The P_H of the surface (0 metres) increased from 8·4 at the beginning of July to 8·7 at the beginning of September, and a similar relative increase was found in all layers down to the bottom. The P_H of the water below 30 metres is about 0·45 less than that of the surface, and from this depth to the bottom (100-200 metres) it is the same, except that just over the bottom a slight decrease (0·02-0·05) was observed. The maximum during calm conditions is found in the layer at 5-6 metres, and this is due to the photosynthetic activity of the phytoplankton.—J. **Gray**: The process of cell division in the eggs of echinoderms. The form of the cleaving egg is due to the growth of the asters and the force exerted by the surface layer of the cell. —V. **Nath**: Oogenesis of Lithobius. The formation of vitelline yolk in the oocytes is preceded by nucleolar extrusions, and the two processes are associated with each other. The fatty yolk is formed from the Golgi rods. Mitachondria are also present.—H. Singh **Pruthi**: Studies on insect metamorphosis—1. Prothetely in mealworms (*Tenebrio molitor*) and other insects. Effects of different temperatures.—H. Munro **Fox**: Chlorocruorin.—C. G. F. **James**: Characteristics of complexes of conics in space of four dimensions.—T. M. **Cherry**: On integrals developable about a singular point of a Hamiltonian system of differential equations.—R. A. R. **Tricker**: A helical method of focussing β-rays.—D. R. **Hartree**: Some methods of estimating the successive ionisation potentials of any element.—Sir Joseph **Larmor**: Why wireless electric waves can bend round the earth (*v.* NATURE, November 1, p. 650).

MANCHESTER.

Literary and Philosophical Society, November 18.—G. **Andrew**: Note on the occurrence of Pachytheca in the Buildwas Beds. A single specimen of Pachytheca extracted from the Buildwas Beds is, so far as is known, the first specimen from this horizon. The specimen is a black carbonised sphere, diameter about 3 mm., and the surface originally was unbroken, but with a few irregular cracks. Subsequently the outer layer became fractured, displaying the characteristic structure of the organism: a central region, or medulla, surrounded by a cortex about 0·3 mm. thick. The cortex is composed of radiating tubes of about 8 μ diameter. Since the algal filaments are not shown, and since the specimen is single, it is referred to as Pachytheca sp. The Buildwas specimen, associated as it is with a shelly fauna which has not yet been studied in detail from the zonal point of view, cannot be dated accurately. The associated fossils indicate a wholly and definitely marine sediment.—C. L. **Barnes**: The Ben Nevis Observatory. The proposal to erect an observatory on Ben Nevis was first made in 1877 by Mr. Milne Holme, president of the Scottish Meteorological Society, and plans were drawn up, but no progress was made until 1881. In June of that year the late Mr. Clement Wragge began a series of daily ascents, which were continued by himself or an assistant until October. An observatory was opened in 1883, and put in charge of two salaried observers, whose duties were to read all the instruments, with certain exceptions, every hour of the day and night, and to make notes of phenomena such as fogs, haloes, rainbows, coronas, etc. A companion observatory was established at Fort William in 1890, as it was thought that simultaneous observations at the two stations would yield valuable results. In 1896 a smaller station was added, half-way up the mountain. The cost of maintaining the three was about 1000*l.* a year, towards which the Meteorological Office contributed 350*l.*, the remainder being subscribed by various societies and by private individuals. Eventually it was decided that the results were not commensurate with the cost, and on October 1, 1904, the observatory was closed down after twenty-one years of continuous work. The records and the log are accessible in the Transactions of the Royal Society of Edinburgh, vols. 36 and 42-44.

PARIS.

Academy of Sciences, November 3.—M. Guillaume Bigourdan in the chair.—L. **Lecornu**: The deformation of a spherical envelope.—E. L. **Bouvier**: The nidification and the metamorphoses of some saturnian hemileucids.—S. **Winogradsky**: The study of anaerobiosis in arable soil. An account of results of experiments with natural soil to which one per cent. of mannite or glucose was added. As test organisms, Azobacter was chosen as typically aerobic and Amylobacter as anaerobic. The moisture content was allowed to vary, loss of moisture giving increased access of air, and the proportions of the test organisms at various levels determined.—Maurice **Lugeon** and Nicolas **Oulianoff**: The geology of the neighbourhood of Camarasa (Catalonia).—Arnaud **Denjoy**: Series of rational fractions.—A. **Jygmund**: A generalisation of the method of Cesàro.—R. de **Montessus de Ballore**: The evaluation of $\log \underline{n}$.—Alexandre **Kovanko**: Series of functions with one complex variable.—E. **Merlin**: A geometrical property of curved surfaces.—Bertrand **Gambier**: The polygons of Poncelet generalised.—D. **Riabouchinsky**: Some general properties of plane movements of a liquid.—F. **Baldet** and E. M. **Antoniadi**: Observations of cloud-capped protuberances which recently appeared on Mars. The positions and movements of these protuberances, observed between October 10 and 13, are shown in seven drawings.—A. **Brun**: The discovery of a new variable star, with a period probably very short. This star, +80°·5030 in the Greenwich catalogue, varies in magnitude between 12·6 and 13·3 in a period of less than two hours.—T. **Peczalski** and A. **Launert**: The velocity of cementation of copper as a function of the temperature.—Mlles. Marya **Kahanowicz** and Ada **Estrafalaces**: The selective absorption of coloured glasses and the radiometric method for the determination of their reflective

power.—J. **Cojan**: Modification of the method of zones (Ritchey) for the determination of the aberration of optical systems. Its extension to aberrations outside the axis. A series of photographs at different determined positions is taken, and the densities measured by the microphotometer. The accuracy (0·01 mm.) is greater than that obtainable by eye observations.—F. **Guéry**: The magnetic field of the electron in movement. The conclusion is drawn that the magnetic field of the electron is only a mathematical expression without physical reality.—H. **Pied**: The precipitation of tantalum and niobium by cupferron and their separation from iron. After removal of iron as the sulphide in a solution containing oxalic and tartaric acids, tantalum and niobium can be completely separated by cupferron. Titanium, if present, is also precipitated.—Mme. P. **Ramart** and Mlle. **Amagat**: Molecular transpositions. The preparation and dehydration of some α-α-diarylethanols and alkyldiarylethanols.—Léon **Piaux**: The action of catalysts on the oxidation of uric acid: copper and cuprous urate. Both copper powder and cuprous urate serve as active catalysts in the oxidation of uric acid in alkaline solution by oxygen. Potassium oxonate and allantoin are produced.—E. **Kohn-Abrest**: The examination of blood for gaseous poisons. An apparatus is described and illustrated capable of detecting and estimating alcohol, sulphuretted hydrogen, hydrocyanic acid, carbon dioxide and carbon monoxide in 50 c.c. of blood.—Marcel **Solignac**: The eruptive rocks of the archipelago of Galite.—E. **Henrijean** and W. **Kopaczewski**: Colloids and mineral waters. A study of a ferruginous mineral water has proved the presence of a colloid in this water. From its chemical composition, this colloid can be only an electropositive hydrosol of iron.—— **d'Arsonval** and — **Bordas**: Remarks on the preceding note.—E. **Rothé** and Mme. A. **Hée**: The earthquakes observed in France during the year 1923. Fifteen earthquakes were felt in France during the year, the most important being in the Pyrenees region.—Ch. **Brioux**: The influence of urea, used as manure, on the reaction of the soil. Experiments with soil showed that urea, utilised as manure, behaves at first as an alkali on account of its rapid conversion into ammonium carbonate. As the latter is nitrified, it acts as an acid like other ammoniacal manures.—Jules **Amar**: Course of the vital coagulation.—Gabriel **Bidou**: An artificial hand or apparatus for replacing a hand after amputation.—E. **Lagrange**: A reaction of the testicular hormone.—L. M. **Betances**: New details on cytohaematogenesis.—Alphonse **Labbé**: An experimental phylogenetic race. An account of variations in some copepods produced by varying the P_H of sea water.—E. **Gley** and J. **Cheymol**: The presence of iodine in venous blood from the thyroid. It was found that the thyroid gland of the goat yielded sufficient venous blood to permit of the determination of the iodine. The blood in the general circulation also contained iodine. Whilst the proportion of iodine in the blood issuing from each lobe of the gland generally increases with the proportion of iodine in the gland itself, the two are not proportional, and there are probably other controlling factors.—H. **Lagatu** and L. **Maume**: The study, by the periodical analysis of the leaves, of the influence of manures containing lime, magnesia, and potash on the vine.—Louis **Lapicque**: The formula of electrical stimulation as a function of the time.—G. **Sanarelli**: The so-called "intestinal" anthrax. The enteric secretions of the dog, rabbit, and guinea-pig, although without action on the development of several species of organisms (Proteus, Staphylococcus, *B. mesentericus*), completely prevent the development of anthrax spores. These results throw some doubt on the views commonly held on "intestinal anthrax."—C. **Levaditi**, S. **Nicolau**, Mlles. J. **Salgue** and R. **Schoen**: The mechanism of the action of bismuth in syphilis. The destruction of the treponema *in situ* is the effect of quantities of bismuth too small to detect by chemical methods.

Official Publications Received.

United States Department of Agriculture. Department Bulletin No. 1238: The Canker-worms. By B. A. Porter and C. H. Alden. Pp. 38+3 plates. 10 cents. Department Bulletin No. 1243: Studies of the Mexican Bean Beetle in the Southeast. By Neale F. Howard and L. L. English. Pp. 51+12 plates. 20 cents. (Washington: Government Printing Office.)

University of Illinois Engineering Experiment Station. Bulletin No. 143: Tests on the Hydraulics and Pneumatics of House Plumbing. By Prof. Harold E. Babbitt. Pp. 80. (Urbana, Ill.) 40 cents.

The National Institute of Agricultural Botany. Fifth Report and Accounts, 1923–1924. Pp. 19. (Cambridge.)

Meddelelser fra Kommissionen for Havundersøgelser. Serie Fiskeri, Bind 7, Nr. 5: On the Summer- and Autumn-Spawning Herrings of the North Sea. By Dr. A. C. Johansen. Pp. 119. 8 kr. Serie Fiskeri, Bind 7, Nr. 6: Fish Eggs and Larvæ collected in the Belt Sea in March 1922. By P. L. Kramp. Pp. 19. n.p. (København: C. A. Reitzel.)

County Borough of Huddersfield. The Tolson Memorial Museum Publications. Handbook 3: Early Man in the District of Huddersfield. By James A. Petch. With an Appendix on the Nature and Making of Graving Tools, by Francis Buckley. Pp. 95. (Huddersfield.) 1s.

Commonwealth of Australia. Institute of Science and Industry. Bulletin No. 27: Australian Clays in the Manufacture of White Pottery Wares. By R. C. Callister. Pp. 87. (Melbourne: H. J. Green.) Gratis.

Meddelanden från Statens Meteorologisch-Hydrografiska Anstalt. Band 1, No. 5: Översikt över Sveriges vattenkraft. Av Sven Norlindh. Pp. viii+40+3 maps. (Stockholm.) 8.50 kr.

State of Connecticut. Public Document No. 34: Biennial Reports of the Storrs Agricultural Experiment Station, Storrs, Connecticut; including the 32nd Annual Report for the Nine Months ending June 20, 1920, 33rd Annual Report for the Year ending June 30, 1921, 34th Annual Report for the Year ending June 30, 1922, 35th Annual Report for the Year ending June 30, 1923. Pp. xiii+323. (Storrs, Conn.)

Smithsonian Institution: United States National Museum. Contributions from the United States National Herbarium. Vol. 20, Part 13: Revision of the American Species of Rinorea; New Plants from Venezuela; Hemibaccharis, a new Genus of Baccharidinæ. By S. F. Blake. Pp. x+491-554+plates 81-51. (Washington: Government Printing Office.) 20 cents.

Field Museum of Natural History. Zoological Series, Vol. 10, No. 16: Contents and Index to Volume 10, Numbers 1 to 15. (Publication 214.) Pp. ix+375-385. By Frank Wigglesworth Clarke and Henry Stephens Washington. Pp. v+117. 20 cents. (Washington: Government Printing Office.)

Department of the Interior: United States Geological Survey. Mineral Resources of the United States in 1923 (Preliminary Summary). Introduction by Frank J. Katz; Statistics assembled by Martha B. Clark. Pp. iv+130A. (Washington: Government Printing Office.) n.p.

Diary of Societies.

SATURDAY, NOVEMBER 29.

ROYAL IRISH ACADEMY, at 4.15.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section, jointly with the Mining Institute) (at Bolbec Hall, Newcastle-on-Tyne), at 7.

HULL ASSOCIATION OF ENGINEERS (at Hull Municipal Technical College), at 7.15.—W. J. Bowtell: Lifting Machinery for Docks.

SOCIETY OF DYERS AND COLOURISTS (West Riding Section).—Dr. F. M. Rowe and V. Tarbett: The Dyeing Properties of some Azo Derivatives of Tetra Hydro Naphthalene.

MONDAY, DECEMBER 1.

ROYAL SOCIETY, at 4.—Anniversary Meeting.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Monthly Meeting.

SOCIETY OF ENGINEERS (at Geological Society), at 5.30.—H. A. Rickwood: Recent Developments in Ferro-Concrete Cooling Towers.

INSTITUTION OF ELECTRICAL ENGINEERS (jointly with the South Wales Institute of Engineers) (at Cardiff), at 6.—W. E. Bush: Demonstration on Modern Illumination.

JUNIOR INSTITUTION OF ENGINEERS (North-Western Section) (at 16 St. Mary's Parsonage, Manchester), at 7.15.—B. Spencer: Modern Locomotive Lubrication Practice.

ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street, W.C.), at 8.—Prof. J. A. Smith: Prof. Alexander's Space-Time.

ROYAL SOCIETY OF ARTS, at 8.—Dr. L. C. Martin: Modern Colour Problems (II.) (Cantor Lectures).

SOCIETY OF CHEMICAL INDUSTRY (London Section, jointly with Oil and Colour Chemists' Association) (at Chemical Society), at 8.—Discussion on Protective Paint Coatings.

ROYAL GEOGRAPHICAL SOCIETY (at Central Hall, Westminster), at 8.30.—A selection from M. Albert Kahn's collection of Photographs in Natural Colours, described by A. G. Ogilvie: Physical Geography and Landscapes.—E. A. Benians: Moslem Architecture.—L. H. Dudley Buxton: Man in Relation to his Environment.—Prof. P. M. Roxby: China.

INSTITUTION OF THE RUBBER INDUSTRY (London Section) (at Engineers' Club, Coventry Street, W.).—Major B. J. Eaton: Research Work on the Plantation.

TUESDAY, DECEMBER 2.

ROYAL HORTICULTURAL SOCIETY, at 4.—Lecture.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—A. W. Nash and H. G. Shatwell: Fuel Oil Resources of the Future.—H. G. Shatwell, A. W. Nash, and J. I. Graham: The Somerset Oil Shales.

INSTITUTION OF CIVIL ENGINEERS, at 6.—R. H. L. Pennell and H. Addison: Water-Supplies to the Smaller Provincial Towns of Egypt.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—R. B. Stewart: Fire and Fire Protection.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at 17 Albert Square, Manchester), at 7.

INSTITUTE OF METALS (Birmingham Section) (at Chamber of Commerce, Birmingham), at 7.—W. E. Ballard: Metal Spraying.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Kinematograph Group), at 7.—M. Ruot, K. C. D. Hickman, and others: Colour Stencilling and Tinting.—Messrs. Pathé: Demonstration of their Process of Colour Kinematography, in which the Film is Coloured by a Mechanical Process.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at Coventry), at 7.15.

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7.30.—W. D. McLaren: The Further Development of Large Power Diesel Engines.

INSTITUTE OF METALS (North-East Coast Section) (at Armstrong College, Newcastle-on-Tyne), at 7.30.—G. B. Brook: Aluminium, its Production and Uses.

RÖNTGEN SOCIETY (at British Institute of Radiology, 32 Welbeck Street, W.), at 8.15.—Prof. J. A. Crowther: Some Experiments with Induction Coils.—Prof. J. A. Crowther and R. J. Stephenson: Effect of Capacity on the Induction Coil.

WEDNESDAY, DECEMBER 3.

GEOLOGICAL SOCIETY OF LONDON, at 5.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—G. Shearing: Wireless Telegraph Valve Transmitters employing Rectified Alternating Current.

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7.—G. Rogers: Automatic and Semi-Automatic Mercury-Vapour Rectifier Substations.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at Engineers' Club, Coventry Street, W.), at 7.—H. W. S. Martin: Air Washers and Air Filters.

SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section) (at University College, Nottingham), at 7.30.—Prof. W. E. S. Turner: Glass.

ROYAL MICROSCOPICAL SOCIETY (Biological Section), at 7.30.

INSTITUTION OF SANITARY ENGINEERS (at Caxton Hall), at 7.30.—H. A. Roechling: House Drainage, with special reference to the Intercepting Trap.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—G. Van B. Gilmour: The Analytical Value of the Melting Point of the Insoluble Volatile Acids from Fats.—A. H. Ware: The Use of Mitchell's Ferrous Tartrate Reagent in Qualitative Analysis.—Dr. S. Glasstone: The Influence of Hydrogen Ion Concentration on the Colorimetric Estimation of Pyrogallol and Catechol Derivatives.—B. S. Evans: The Futility of Sealing: A Suggestion for its Safeguarding.

ROYAL SOCIETY OF ARTS, at 8.—Prof. C. A. Carus-Wilson: The Teaching of Science in Secondary Schools.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

THURSDAY, DECEMBER 4.

ROYAL SOCIETY, at 4.30.—Prof. A. Fowler: The Structure of the Spectrum of Ionised Nitrogen.—Dr. H. Jeffreys: The Formation of Water Waves by Wind.—J. E. Jones: (1) The Determination of Molecular Fields. III. From Crystal Measurements and Kinetic Theory Data. (2) On the Atomic Fields of Helium and Neon.—F. S. Tritton: A Centrifugal Method of making Small Pots of Electrically Fused Refractory Materials.—*To be read in title only*:—Prof. J. W. Nicholson: Spheroidal Wave Functions.—J. V. Howard and S. L. Smith: Recent Developments in Tensile Testing.—F. C. Harris: The Photo-Elastic Constants of Glass as affected by High Temperatures and by Lapse of Time.—Prof. A. L. Narayan and D. Gunnaiya: Absorption and Dispersion of Thallium Vapour.—R. d'E. Atkinson: Note on Vegard's Theory of the Aurora.—Mollie Weinberg: The Spark Spectra of Indium and Gallium in the Extreme Ultraviolet Region.—S. W. Richardson: The General Law of Electrical Conduction in Dielectrics.—T. Lewis: The Interpretation of the Results of Bucherer's Experiments on e/m.—A. M. Mosharrafa: The Quantum Dynamics of Degenerate Systems.—E. G. Dymond: The Precise Measurement of the Critical Potentials of Gases.—I. Langmuir and K. H. Kingdon: Thermionic Effects caused by Vapours of Alkali Metals.

LINNEAN SOCIETY OF LONDON, at 5.—Dr. G. C. Druce: Exhibition of *Epipogum aphyllum*, and other British Plants.—Miss V. Hay: The Adult and Juvenile Forms of *Sophora tetrap'era* vars. *microphylla* and *prostrata*.—Miss V. M. Grubb: The Development and Liberation of Spermatia in some previously undescribed cases.—Prof. E. S. Goodrich: The Cranial Roofing-bones in Dipnoi Fishes.

ROYAL AERONAUTICAL SOCIETY (at 7 Albemarle Street, W.), at 5.30.—Col. F. Searle: The Maintenance of Commercial Aircraft.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. Octavia Lewin: Some Physical Causes of Mental Deficiency.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—Prof. J. G. Gray and J. Gray: Gyroscopic Pendulums.

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (at Bristol University), at 7.30.—W. E. Fearnsides: Some International Aspects of the Dye Industry.

INSTITUTE OF METALS (Sheffield Section, jointly with the Silver Trades Society) (at Sheffield University), at 7.30.—A. Jefferson and others: Discussion on Electro-Plating.

CHEMICAL SOCIETY, at 8.—H. Burgess and Prof. T. M. Lowry: (*a*) New Halogen Derivatives of Camphor. Part VI. β-Bromocamphor-α-Sulphonic Acid; (*b*) New Halogen Derivatives of Camphor. Part VII. The Constitution of the R-ychler Series of Camphorsulphonic Acids. Experiments on Chlorosulphoxides.

ROYAL SOCIETY OF MEDICINE (Dermatology, Laryngology, and Odontology Sections), at 8.—J. F. O'Malley, Dr. H. W. Barber, and others: Discussion on Focal Sepsis in relation to Diseases of the Skin.

INSTITUTION OF MECHANICAL ENGINEERS (Glasgow Section).—Report of the Marine Oil-Engine Trials Committee.

INSTITUTION OF MECHANICAL ENGINEERS (Manchester Section).—Report of the Marine Oil-Engine Trials Committee.

FRIDAY, DECEMBER 5.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Lt.-Col. R. McCarrison: Problems of Food, with special reference to India.

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.—Col. H. G. Lyons and Sir G. P. Lenox-Conyngham: The Use of Submarines in the Determination of Gravity at Sea. Chairman: Prof. G. I. Taylor.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (at Liverpool University), at 6.—Dr. P. Lewis-Dale: Liquid Hydrocarbons obtained in the Compression of Oil Gas.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Prof. F. C. Lea: The Effect of Low and High Temperatures on Materials.—J. M. Lessells: The Elastic Limit in Tension, its Influence on the Breakdown by Fatigue.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7.—L. Wood: Matters Pictorial.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at 16 St. Mary's Parsonage, Manchester), at 7.—A. V. Slater: Peptisation.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—J. B. Pollard: Metal Cutting under Water by the Oxy-acetylene Blow Pipe.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Cleveland Institution, Middlesbrough), at 7.30.—L. W. E. Rowbotham: Constructing a Ship.

PHILOLOGICAL SOCIETY (at University College), at 8.—R. J. Whitwell: Future of N.E.D.

INSTITUTION OF MECHANICAL ENGINEERS (Liverpool Section).—Report of the Marine Oil-Engine Trials Committee.

SATURDAY, DECEMBER 6.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.), at 3.—E. W. H. Piper: Durham Cathedral (Lecture).

INSTITUTE OF BRITISH FOUNDRYMEN (at Chamber of Commerce, Birmingham), at 4.—D. Wilkinson: Malleable Iron.

PUBLIC LECTURES.

SATURDAY, NOVEMBER 29.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—S. H. Warren: Prehistoric Man and the "Land of Lyonesse."

TUESDAY, DECEMBER 2.

KING'S COLLEGE, at 5.30.—Miss Hilda D. Oakeley: The Philosophy of the Absolute in English Thought: The Eternal and the Temporal.

WEDNESDAY, DECEMBER 3.

MEDICAL SOCIETY OF LONDON, at 5.15.—Dr. W. M. Feldman: Post-Natal Child Physiology and Hygiene (Chadwick Lecture).

UNIVERSITY COLLEGE, at 5.30.—I. Björkhagen: Sweden: Its Land and People.

THURSDAY, DECEMBER 4.

BEDFORD COLLEGE FOR WOMEN, at 5.15.—Dr. J. F. Spencer: The Historical Development of Conception of the Atom.

KING'S COLLEGE, at 5.30.—M. Beza: Pagan Remnants in Roumanian Folklore. (Succeeding Lecture on December 11.)

FRIDAY, DECEMBER 5.

KING'S COLLEGE, at 5.30.—Dr. E. S. Russell: Scientific Method.

SATURDAY, DECEMBER 6.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. N. Milligan: The Eggs of Animals.

The Development of Industrial Research Associations.

MANY of the Research Associations, founded under the auspices of the Department of Scientific and Industrial Research, have been in existence for five years, and consequently it is possible to form some idea of their future development and usefulness.

The reasons for their establishment are well known. It was recognised that British industries are in the main highly developed arts and crafts, basing their technical methods on slowly gained practical experience rather than on the broader foundations afforded by scientific method. The knowledge in any industry consists of a number of well-established but often unrelated facts; what is lacking is the scientific substratum which binds these facts into a coherent whole.

It must be clear to all who have given thought to the subject, that industries established in this manner now find that, before much further advance can be made, problems of such a fundamental and purely scientific nature have to be faced that no single firm could undertake their solution. Generally speaking, British industry in the past has fought shy of research, especially of the more fundamental kind. The necessity for it is, therefore, all the more pressing. Fortunately, industrial leaders have a growing belief in its utility, and are readier than ever before not only to avail themselves of the results that research can place at their disposal, but also to bear its cost. The only debated point with them has been the nature of the scheme to be adopted in order to bring about the desired end. In these circumstances it is hard to conceive a better plan than that evolved by the Department of Scientific and Industrial Research, since for the first time it enables fundamental problems to be worked on by an Association representative of, and supported by, the whole industry, which is ready to pool its experience and place it at the disposal of the scientific workers who are responsible for carrying out the investigations.

Probably, if Research Associations did not exist, British industry would still be chary of recognising its obligation to undertake fundamental research work, and the fact that industrial belief in Research Associations is undoubtedly spreading, constitutes one of the strongest arguments in favour of the creation and continuance of these bodies.

Research Associations have many advantages over academic research institutes in attacking industrial problems which, as a rule, are many-sided scientifically, and require not only deft handling by an expert in any one science, but also organised and co-operative attack by experts in several sciences. Nor does the matter end here, for when the scientific data are ascertained

and the laboratory solution has been found, there still remains what is often the most difficult and costly part of the work, namely, the application to large-scale practice. Neither the man of science nor the technologist can, individually, handle this side of the question successfully: the closest co-operation is necessitated, in which the technical side must be represented by both employers and employed. The future success of Research Associations largely depends on the reality and effectiveness of this co-operation.

Far-reaching inquiries into the scientific foundations of industrial practice are not, however, likely to bear fruit in a brief period of time; and on this account great faith and patience are required on the part of those who are supporting them. How are this faith and patience to be created? The hard-headed business man with no knowledge of scientific method would not be won over by the statement "subscribe to the Association for five, ten, or perhaps fifteen years and good will come to you." He is, however, strongly appealed to when he sees everyday difficulties surmounted, and newly discovered facts, which probably at first he regarded with little interest, usefully applied in unexpected directions. The gradual accumulation of scientific data should make it comparatively easy for Research Associations to give this form of assistance.

This raises the question, to what extent should Research Associations do consulting work? This is undoubtedly not their prime object; yet it seems inevitable that some work of this description will have to be undertaken, for as the confidence of a trade in its Association increases, so naturally will the desire of the former to refer more and more of its difficulties to the latter. Moreover, the solution of these minor problems is of undoubted educational value to the scientific staff of an Association, who, as they are devoting their whole energies to the scientific side of a trade, must eventually become "the" authorities in their respective branches. The relative amount of such work to be undertaken must be left to the decision of the governing body of each Association, but the most useful test to apply in relation thereto should be: Is the particular point raised of importance to the trade in general, or does it affect one firm only? If the former, the work might well be done and the solution given to the trade as a whole. But it must never be forgotten that, although this kind of work can greatly improve general efficiency, it is unlikely to effect a revolution in any industry. Really great advances can only result from the discovery of new starting-points, which will be established by probing more deeply into the intrinsic properties of the raw materials employed, and by laying bare the scientific principles involved in each process of manufacture.

Five years—the first period of Government support to the Research Associations—is certainly too short a time in which to prove the value of fundamental scientific work to those who have never had any knowledge of its possibilities, especially when the scientific staffs of Research Associations have had to acquire a considerable knowledge of technical detail of the industry, and perhaps the additional five years, for which new grants have been made, may not prove adequate to allow the Associations so to gain the confidence of their trades as to render outside assistance no longer necessary. It is, however, at once granted that such must be the ultimate goal, and there seems little doubt but that the goal will be reached. In support of this statement no more striking example could be quoted than that of the cotton industry, the members of which have recently proved their faith in co-operative research by agreeing to double their subscriptions to their Association and to guarantee them for five years. The Cotton Research Association has now an assured income of more than 40,000*l.* a year, and although this sum may be considered small for an industry of the magnitude of that concerned with cotton, and further, may not be sufficient to allow the fullest possible developments at the moment, it is at least sufficient to demonstrate the value of what may well prove to be one of the greatest movements in the advance of modern British industry.

It is hoped that many of the trades which have entered into the scheme may reap early benefit as a result of their foresight, but the main object in the founding of Research Associations was surely not so much consideration for the immediate present, as a desire to associate science with industry in such a manner that the future would show the continued supremacy of British trade, on which the welfare of the nation depends.

KENNETH LEE.

The Life of Lord Rayleigh.

John William Strutt, Third Baron Rayleigh, O.M., F.R.S., Sometime President of the Royal Society and Chancellor of the University of Cambridge. By his Son, Robert John Strutt, Fourth Baron Rayleigh. Pp. xi+403+5 plates. (London: E. Arnold and Co., 1924.) 25*s.* net.

LORD RAYLEIGH has completed a very difficult task with great success; he has written a life of his father which has the intimacy which only near relationship could give, combined with a frankness which leaves the conviction that he has shown true filial piety by omitting nothing that would help to make his portrait of a very great man true to life. He says in the preface that it has been his aim not so much

to give an account of his father's scientific work as to depict him as a man. He tells us about his father's boyhood, how he went first to Eton and then after an interval to Harrow; bad health, however, prevented him from staying more than a term or two at either. The greater part of his school education was at Mr. Warner's, a well-known private school at Torquay, a school by the way where no unmarried lady of less than sixty years of age was to be mentioned at the dinner table. The love for a joke, which Rayleigh never lost, began soon, for we find from a letter written at school that he and another boy invented a language which they called Russian, and set the smaller boys at work learning the declensions. The mathematical teaching at Warner's seems to have been good, and Rayleigh remained there until within a few months of going up to Trinity College, Cambridge. As a boy he was very fond of photography, which he began at about the time when he went to Warner's, and he often in after life declared that he owed much to the practice he got in manipulation with the old wet collodion process.

Between the spring of 1861, when he left Warner's, and the October of the same year, when he came to Trinity, Rayleigh began with a private tutor to read the differential calculus, so that his stock of mathematical knowledge as a freshman was a great contrast to that of Lord Kelvin, who had written papers on Fourier's theorem before coming to Cambridge; it was, however, greater than that of Stokes, who had not commenced the differential calculus when he came into residence. At the time when Rayleigh was an undergraduate, the teaching of mathematics to the best men was very largely in the hands of Routh. College lectures counted for little, and professor's lectures for still less. Routh's method of teaching was as different as possible from the popular idea of private coaching. It consisted of admirably clear and carefully prepared lectures given to a class of perhaps ten or twelve pupils. Many examples were set for solution, and each week there was a problem paper the marks for which were made public so that it acted as an incentive. Lord Rayleigh expressed in a speech quoted in his biography the gratitude which he and many other pupils felt to Routh for his teaching. At Routh's the physics were in abeyance, and when in his third year Rayleigh attended Stokes's lectures on optics, it was an epoch in his life. "This was what I really liked," he said many years afterwards, quoting from his note of Stokes's lectures: "a beam of coloured light was passed through a dilute alcoholic solution of the green colouring matter of leaves; the transmitted rays were green, but the part of the liquid traversed by the rays shone with a deep blood-red light."

Rayleigh prepared with great care for the tripos examination, going so far as to study the idiosyncrasies of the examiners so as to form some idea of the questions they were likely to set. Like others before and after him, he was reduced to despair by the problem paper in the first part of the tripos: a diabolical contrivance full of "low mathematical dodges." However, all went well in the end, and he came out senior wrangler and first Smith's Prizeman in January 1865. Marshall, the political economist, was second wrangler, and H. M. Taylor third. Some of Rayleigh's answers were so good that one of the examiners said they might have been sent straight to press without correction. The correspondent of the *Times*, in announcing the result of the tripos, said that "the success of Mr. Strutt is attributed more to his perseverance than to his brilliant talent"! It is disconcerting to find that when at Trinity the future Chancellor indulged in roof-climbing about the College, a practice which now at any rate is not regarded with favour by the authorities. He also played real tennis; one result of this was his delightful little paper "On the irregular flight of a tennis ball."

After taking his degree Rayleigh found great difficulties in getting opportunities for experimental research or instruction in laboratory work. This, he said afterwards, "wasted three or four years of my life." In 1868, after a trip to America, he started experimenting on his own account at Terling, and in the course of the next ten years published, along with many other things, papers on the theory of resonance, on the scattering of light by small particles, on the resolving power of optical instruments, and his great book on the "Theory of Sound."

When on Clerk-Maxwell's death in 1879 the professorship of experimental physics at Cambridge became vacant, Lord Rayleigh received an invitation, signed by 125 members of the Electoral Roll, inviting him to become a candidate for the professorship. After considerable hesitation he accepted the invitation and was elected to the professorship in December 1879. He began at once to reorganise the laboratory and the teaching. Finding the supply of apparatus inadequate, he raised a fund of 1500*l.*, towards which he gave 500*l.*, for buying more. In collaboration with Glazebrook and Shaw he organised a system of teaching practical physics which is in essentials the same as that still in force. His own work before coming to Cambridge had not been especially on electrical subjects; but, as he told me, he found that the interest which Maxwell had aroused in electricity was so strong that he was led himself in the same direction. He organised and carried out, with the assistance of Mrs. Sidgwick and Sir Arthur Schuster, those classical determinations of the fundamental electrical units which raised electrical measurements to a new level. An admirable account of these investigations is given in the

biography. In starting the work on electrical units he had in his mind a scheme of identifying the laboratory with a research planned on an extensive scale in which a large number of workers in the laboratory might take part. I think it is doubtful whether, considered from the point of view of training for young physicists, such a scheme is advantageous in a university laboratory. Most men are much more interested in, and more enthusiastic about, one branch of physics than another, and a young man develops his powers more rapidly and puts more independent thought into his work if he tackles a problem which he has, to some extent, selected for himself, than if he joins a scheme of work already planned.

As one who worked in the laboratory while Lord Rayleigh was professor, I can testify to the assistance we got from him; there never was, I think, a man whose judgment in scientific matters was sounder or more free from prejudice; if he questioned a conclusion or a result one felt there was a real difficulty which required further investigation. Yet even with these qualities he found prophecy was not free from danger. He says in a letter written at this period: "Yesterday I had an opportunity of seeing the telephone which every one has been talking about . . . it is certainly a wonderful instrument, though I suppose not likely to come to much practical use." Having quoted a bad guess I ought not to omit a good one in his presidential address to the Royal Society in 1908. He says: "We may expect to see flying machines in use before many years are past."

Lord Rayleigh had only undertaken to hold the professorship for five years, and at the end of 1884 he resigned. In spite of attacks of rheumatic fever he had worked desperately hard and published sixty important papers in five years. Mr. Gordon, who had been his assistant at the Cavendish laboratory, went with him to Terling; it is pleasant to find in the biography kindly reference made to Gordon, who, by the assistance he gave to Lord Rayleigh, rendered good and faithful service to science.

On leaving Cambridge in 1884 Lord Rayleigh continued his experimental work in his laboratory at Terling. The absence of the facilities of a large laboratory would have been a serious handicap to most men, but Lord Rayleigh possessed to an extraordinary degree the power of getting important results with simple apparatus: it has been said of him that he only required a few pieces of glass tubing and a stick of sealing-wax to make the most fundamental discoveries. It was immediately after leaving Cambridge that he began the work which led to his discovery of argon and incidentally caused him much annoyance. The story of the discovery of argon is told by his son in a chapter which is a masterpiece of clear and impartial statement; every line carries conviction, and after reading it we are convinced that there is nothing further to be said on the subject. The discovery of argon is a most striking instance of the necessity of utilising physical methods in chemical analysis—what can they know of chemistry who only chemistry know?

Besides his almost unparalleled activities in research, Lord Rayleigh did no inconsiderable amount of official and executive work. These aspects are dealt with in the biography in a chapter on "Public Work": a very clear and interesting account of the foundation of the National Physical Laboratory is given, and the debt which that laboratory owes to him is certainly not overestimated. He was the chairman of the Treasury Committee which in 1898 reported in favour of establishing the laboratory, and he was chairman of the executive committee to which it was entrusted from the time of its formation until shortly before his death. His judgment, his wisdom and his influence contributed in no small measure to the growth of that institution from very modest beginnings to the foremost place among National Physical Laboratories. His work at the Royal Society, at the Royal Institution, as scientific adviser to Trinity House, and as gas referee, are admirably described.

Not the least interesting part of the book is the account of Lord Rayleigh's connexion with psychical research. As a young man he realised the immense importance of the subject, and it is stated in the biography that he contemplated throwing the greater part of his energies into the investigation of such problems. He says in a letter written in 1874: "A decision of the existence of mind independent of ordinary matter . . . would be the most important possible scientific discovery." He attended many seances, but came, as others have done, to the conclusion that he was unlikely from his own personal experience to be able to arrive at conclusions definite enough to justify him in making it his life work. In his presidential address to the Society for Psychical Research a few months before his death, and showing that clearness of thought and perception of essentials so characteristic of him, he offers no definite opinion, but says: "Some of those who know me best think that I ought to be more convinced than I am. Perhaps they are right."

Lord Rayleigh was a lover of good stories, and a list of some of those which appealed to him is given in an appendix to the biography. This is a novel feature in a book of this kind, but it makes us, I think, feel we know him better than if it had been omitted.

Lord Rayleigh has been fortunate in his biographer, for no one can read this admirably written work without increased admiration and respect for one of the great names in British science, a great discoverer and a counsellor whose judgments were never clouded by prejudice or by a shadow of self-seeking. J. J. THOMSON.

Practical Farming.

(1) *The Production of Field Crops: a Textbook of Agronomy.* By Prof. T. B. Hutcheson and Prof. T. K. Wolfe. (McGraw-Hill Agricultural and Biological Publications.) Pp. xv+499. (London: McGraw-Hill Publishing Co., Ltd., 1924.) 17*s.* 6*d.* net.

(2) *Grassland Farming, Pastures and Leys.* By W. J. Malden. Pp. xxiv+314. (London: Ernest Benn, Ltd., 1924.) 30*s.* net.

THE agricultural industry is passing through a critical period not only in Great Britain but also—if for very different reasons—in the United States of America. It would almost appear as if these difficult times are operating to bring the man of science and the man of practice closer together, and as if the movement in the direction of universal agricultural education and research, quickened by the stress of adversity, is on the threshold of bearing very substantial fruit. It is a noteworthy fact that the later post-War period has been remarkable for the appearance on both sides of the Atlantic of a large number of books on agricultural subjects. There has been discernible in many of these books a tendency to write as much, or more, for the benefit of the farmer as for the enlightenment of the student.

This tendency is well exemplified in the two volumes under notice, and is shown by nothing so much as the fact that the chapters are not burdened with attempts to teach elementary chemistry or elementary botany or with digressions in the realm of pure science irrelevant or more or less irrelevant to the subject matter. The subjects under discussion are dealt with from the practical point of view and with resort to the minimum of technical terms. It is presumably coming to be realised that the farmer does not wish to be taught the technicalities of science, but he demands that the practical information and advice given him shall be both correct and sound; it must therefore be based on accurate scientific knowledge born of experimentation, and should be backed by prolonged farming experience.

(1) The work of Profs. Hutcheson and Wolfe constitutes the nineteenth of the excellent series of agricultural and biological publications of which Dr. Charles V. Piper is the consulting editor, and is based almost entirely on the results of properly conducted field trials.

The authors state that the standard introductory course in field crops recently adopted by the American Society of Agronomy (see Journal of the American Society of Agronomy, vol. 14 (4), April 1922; vol. 15 (2), February 1923; and vol. 16 (1), January 1924) has been followed as closely as practicable. The work is therefore essentially a text-book adapted for the use of American farmers and students, and deals explicitly with American conditions. This is emphasised by the fact that of the 396 citations in the bibliography, all except about a dozen refer to American investigations.

The book should be of considerable value, however, not only to the British student seeking accurate information with reference to American crops and to American literature, but also to such as desire concise information, based on scientific investigation, as to the fundamentals of successful crop production. Thirty-seven of the forty-five chapters are devoted to a general discussion of the culture of crops. In addition to subjects like tillage, fertilisers, and lime, which in the past have so largely dominated works on crop production, it is significant of the American point of view that no less prominence is given to the treatment of the factors more or less inherent in the crop itself, such as the adaptation of crops, crop improvement, and the value of good varieties and of good seed. The part that seed associations of farmers have played in the distribution of improved or suitable varieties and of good seed, based on the extensive trials undertaken by the Experimental Stations, is emphasised in these chapters and should afford food for thought to the British agriculturist. Similarly the chapter on grain grading directs attention to an important question which has recently been given much prominence by the teachers of farm crops in the various agricultural colleges in the United States. Grassland is adequately dealt with in chapters on haymaking, pasture, and meadow management.

The chapters on the individual crops are enhanced in value by maps indicating the geographical range of cultivation of each within the United States, and in the case of the more important crops the belts devoted to certain groups of varieties in particular are also shown, while statistics are given both as to world production and to production within the United States.

(2) Mr. Malden's volume on grassland farming is severely practical, and the information supplied, although supplemented by references to numerous trials, is based largely on the author's considerable experience of farming. That the results of exact experimentation have not been more extensively drawn upon, or at all events not more extensively relied upon, is perhaps in the main to be accounted for by the simple fact that very little experimental work bearing explicitly on the management of grassland as a whole—as opposed to experiments on isolated aspects of grassland husbandry, such as manuring, seeding-down, and the like—has been conducted in Great Britain. In several instances,

however, the author undoubtedly attaches more importance to his own interpretation of his own experiences than to the largely accepted teaching of more or less recent experimental trials. This is noteworthy in respect of his paragraphs relative to the feeding of cake on grassland, and as to the use of inorganic nitrogenous fertilisers on pastures; it is also apparent that the author has a decided predilection in favour of the so-called complicated mixture. Thus on p. 87 he quotes and apparently approves of a seeds mixture for light land consisting of sixteen species, no less than four of which are included in amounts of less than 1 lb. It is true that at the end of the chapter on seeds mixtures he quotes, but without comment, those of a simpler character recently advocated by the Royal Agricultural Society.

In the chapter "Plants of Permanent Pasture" valuable and concise information is given relative to the chief species; it is unfortunate, however, that the author perpetuates the term "cow-grass" for single cut cow grass or late flowering red clover, and that he also quotes without contradiction the time-worn view that this strain of red clover originated from crossing *Trifolium pratense* with *T. medium* or zigzag clover, a view for which there is no possible botanical justification.

The chapters on the management of temporary and permanent pastures are exceedingly interesting and very suggestive, while that on haymaking should be read with the greatest care by every farmer who operates in regions of high rainfall. R. G. S.

The Manufacture of Sulphuric Acid.

(1) *The Manufacture of Sulphuric Acid (Chamber-Process)*. By W. Wyld. ("The Manufacture of Acids and Alkalis," by George Lunge. Completely revised and rewritten under the Editorship of Dr. A. C. Cumming. Vol. 2.) Pp. xii+424. 31*s.* 6*d.* net.

(2) *The Concentration of Sulphuric Acid*. By J. W. Parkes. ("The Manufacture of Acids and Alkalis," by George Lunge. Completely revised and rewritten under the Editorship of Dr. A. C. Cumming. Vol. 3.) Pp. xii+394. 31*s.* 6*d.* net.

(London and Edinburgh: Gurney and Jackson, 1924.)

THERE is no treatise in any language which gave more detailed accounts of the manufacture of sulphuric acid than that of Lunge. The earlier editions of this were based directly on the experience of the author and were very practical. In the course of revision the new matter took the form of extracts from patents, and very little critical discussion of these was added. In the latest edition, two volumes of which form the subject of the present review, there is considerable difference in the method of treatment.

(1) The new volume dealing with the chamber process is essentially the same as the later editions of Lunge, but a fair amount of the text of these has been omitted. The new matter added consists mainly of rather sketchy descriptions of pumps for acid and of patent packings for towers. The practical details of construction and working remain essentially those of Lunge, so that the larger volume of the previous edition will remain perhaps the more complete account of the subject. The new diagrams also are of a sketchy character, *e.g.*, that on p. 83 representing a tower system used by Mr. Wyld. The description of this occupies only about half a page, and the diagram is merely a rough sketch. The description of tower systems consists mainly of brief extracts from patent specifications.

Mr. Wyld states in the preface that he is himself carrying out extensive investigations on tower plant, and it would seem that it would have been wiser to have deferred the publication of this volume of the series until information of practical value had been obtained. Even if the book is to be considered merely as a collection of patent references, then it must be regarded as incomplete. The lack of detailed new information may be merely an indication that the chamber process has not been found capable of improvement, but there was obviously need for a fuller and more critical discussion of the newer tower systems. It is assumed that all the references given in the former edition have been checked with the originals; some were incorrect, and at least one is incorrect in the present edition.

(2) Mr. Parkes's volume dealing with the concentration of sulphuric acid is a very decided improvement of the previous edition of Lunge's book and contains a large amount of new information of great practical value. Much of this is derived from the experience gained during the War in the national factories. The admirable methods of control used in these factories have resulted in the accumulation of a large amount of important and useful information which is now collected, arranged, and critically discussed in one volume.

There can be no doubt that Mr. Parkes's book will be the standard treatise on the concentration of sulphuric acid. The densities are given in accordance with Domke and Bein's work, and the thermal data are collected from the critical memoir of Prof. A. W. Porter. The calculations based on these figures are therefore the most accurate available, and the results may be safely assumed as a basis of plant design. The newer types of concentrating plant, such as the cascades of various materials, the Gaillard tower, the Gilchrist apparatus,

and the modern Kessler plants, are described in full detail, with excellent working drawings and reproductions of photographs of actual plant. The condensation of fumes, a most important part of the operation of a concentration plant, is discussed, and the Cottrell and Calder-Fox systems described. The recovery of waste acid and the transport of acid are also included.

Mr. Parkes's revision has been thorough, and his book is a complete treatise on the theory and practice of the concentration of sulphuric acid. J. R. P.

Psychology as a Science.

The Nature of Intelligence. By Prof. L. L. Thurstone. (International Library of Psychology, Philosophy and Scientific Method.) Pp. xvi+167. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co. Inc., 1924.) 10*s.* 6*d.* net.

THE fact which is, perhaps, most obvious to readers of psychological literature is that each School uses language which is entirely unmeaning when applied to another School; the behaviourist, the experimentalist, the psychiatrist, and the academic psychologist all appear to be talking in different languages, and Prof. Thurstone attempts both to unravel the reasons of the medley and also to construct an intelligible science out of it. His book is thus the first real attempt to bring into a composite whole the different branches of psychology and, for that reason alone, commends itself to all serious students.

Prof. Thurstone finds the chief reason of the differences to be that the specialists lay stress on diverse entities in conduct; they look at the subject from entirely dissimilar points of view, and (in the author's view), wrongly, build up a science which is not really true to the facts. Thus the behaviourist stresses "overt conduct," the experimentalist mere stimulus and response, the academician "consciousness and its states," and the psychiatrist abnormal psychology. The author, however, would combine the different points of view and, by shifting the stress of the special branches, construct a science at once more human and accurate.

Our author begins by showing how the stimulus-response theory must give way to the theory that impulses generate in the organism and only use stimuli in so far as they are able to satisfy the feeling generated by the activity. He then goes on to show that consciousness is an evolutionary development the sole use of which is that it leads to activity and thereby helps to gain the object desired. But this is not enough. After consciousness and its states we must have the overt act, the behaviour of the organism in order to complete the cycle. Thus a complete view of psychology begins with the "energy-source" in the individual, passes through consciousness by means of ideation to the external stimuli, proceeds to the overt act, and ends with the satisfaction of the impulse and the quiescence of the "energy-source." Looked at from this basis, intelligent conduct depends upon whether it is possible for the individual to focus in consciousness at an early stage of the impulse the specific universal meaning of the impulse and thereby make use of "trial and error" conduct. Grades of intelligence are grades of powers of inhibition, powers, that is, effectively to control mere reflex actions in order better to satisfy the impulse.

We cannot enter into details of the book. It is doubtful whether Prof. Thurstone really means the phrase "consciousness is unfinished conduct"; if he does, then he is severely limiting the use of the word "consciousness" and his definitions, both of consciousness and intelligence, appear to savour of descriptions, and, at any rate, are both debatable. The book, however, is simply written and is illuminated by profuse and clear diagrams, and his theory is backed up by a wealth of good psychological examples. It should be read, if only as a stimulus to thought and to give a clear view of the real need for a science which will combine the different branches of psychology.

Cotton in Australia.

Cotton in Australia: the Possibilities and the Limitations of Australia as a Cotton-growing Country. By Richard Harding. Pp. xviii+270. (London: Longmans, Green and Co., 1924.) 12*s.* 6*d.* net.

THE author describes this book as the result of eighteen months' investigation made in Australia, when secretary of the British Cotton Delegation, 1922. He sets out to prove that great areas of that continent can produce cotton commercially; of course he succeeds. At first one is inclined to resent the facile optimism of the fourth chapter, which is especially devoted to this proof, where the author openly omits a drought year from his averages and guesses the available resources in six significant figures; but having duly discounted his rather uncritical attitude, we can welcome this book as the first available general statement of the Australian cotton position. That the country has large potential cotton areas is clear; the Government proposes to face the basic difficulty of getting labour for the picking season (from white men in a cotton-growing climate) by planting many small areas, each on one man's small holding. Whether the plan will work remains to be seen, but Mr. Harding certainly puts his finger on two essentials; one is the cultivation of a big boll type, since the labour of picking a given weight of crop is almost inversely proportional to the boll weight; the other is the advisability of insisting

on quality, though we think he perhaps overrates here the agricultural virtue of the white as compared with the coloured man.

Structurally the book is weakened by a dual purpose. Not only does it present Australian cotton to the rest of the world—for which we welcome it, though more explicit references to sources of data would be useful—but it has also another purpose; and both would have been better achieved by shuffling the chapters into two parts. This second purpose, not explicitly stated by the author, is the presentation of the world's knowledge of cotton to the Australian; and this is necessarily a compilation. Some obsolete matter and ancient tags are included in the first two chapters, which are of dubious value; we have often heard previously of Lancashire's climate (p. 19) and men of business (p. 18); the point is missed that the Nigerian cotton supply to us is merely surplus production from their own local cotton industry (p. 23); and the artificial silk industry is making long-distance predictions of cotton consumption (p. 28) rather risky. The chapters on seed supply and cultivation, which have the same instructive aim, are of real use; the author describes some procedures which certainly ought to be followed as if they commonly were followed, thus giving a valuable tinge of practical idealism, perhaps deliberately, to his exposition. Some statistical and descriptive appendices, also of dual purpose, complete the book, which, though in many ways unsatisfactory, will be useful not only in Australia, but also outside. W. LAWRENCE BALLS.

Our Bookshelf.

(1) *The Common Sense of the Theory of Relativity.* By Dr. Paul R. Heyl. Pp. 44. (Baltimore, Md.: Williams and Wilkins Co., 1924.) n.p.

(2) *Relativity for Physics Students.* By Prof. G. B. Jeffery. Pp. vii+151. (London: Methuen and Co., Ltd., 1924.) 6*s.* net.

(3) *The Foundations of Einstein's Theory of Gravitation.* By Erwin Freundlich. Translated from the Fourth German edition, with Two Essays, by Henry L. Brose. Second edition, revised and enlarged. Pp. xvi+140. (London: Methuen and Co., Ltd., 1924.) 6*s.* net.

(4) *Darstellung der Relativitätstheorie im Dreidimensionalen Lobatschefskijschen Raume.* Von Prof. Vladimir Varićak. Pp. x+104. (Zagreb: Zaklada Tiskare Narodnih Novina, 1924.) n.p.

HERE are four more books on relativity, ranging from the highly popular and amusingly written booklet of Dr. Heyl to the extremely technical and ponderous representation of the theory in three-dimensional Lobatschefsky space. (1) The common sense of relativity can apparently be expounded in 44 pages of light reading for the man in the street, but naturally this is possible only by a use of analogies which must not be too closely scrutinised. We doubt whether it is actually "common sense" which is content to be fobbed off in this way. Nevertheless, as a booklet for whiling away a half-hour's railway journey, it is admirable.

(2) Prof. Jeffery's book is on a different plane. It introduces the theory to students of science capable of using their mathematics to a moderate extent as an instrument of thought, but not yet fully equipped with the mathematical weapons required for the thorough investigation of the subject. The result is an excellent little book which we trust all science students still nervous and suspicious of a field apparently subversive of their training, will study carefully. The ideas are clearly and concisely expounded before any mathematical treatment is entertained, and even then the analysis is economised to correspond closely to the object in view.

(3) That the translation of Freundlich's book is worth study there can be no doubt, but it is needlessly difficult to read, not so much because it is a translation but because so much more has been included between the covers than the original work. An introduction by H. H. Turner (8 pp.), followed by the material giving the title to the book (68 pp.), then 28 separate notes to this material (36 pp.), and tacked on at the end two essays by the translator (35 pp.), all contribute to produce a lack of homogeneity and the impression that the same courses are being served up several times under different guises.

(4) This is an interesting and lucid analysis of Lobatschefsky space, displaying its properties in such a form as to present their intimate relationship with the ideas of relativity.

Everyday Physics. By H. E. Hadley. Pp. viii+474+4 plates. (London: Macmillan and Co., Ltd., 1924.) 6*s.* 6*d.*

THE headmaster of a secondary school has to solve the problem of providing a satisfactory course of general science for the average pupil (including the budding specialist in language or history) along with a course which will equip a student of science for an advanced course in chemistry and physics. The chemistry of air and water, so far as it is necessary for the study of geography and botany, is taught in most schools in Great Britain to boys and girls alike, and presents no great difficulty; but the subject of physics, which is subdivided by examining bodies into three heads, becomes a Cerberus guarding the gate of a sound general education. To pass an examination *either* in heat, light, and sound, *or* in mechanics, *or* in electricity and magnetism may give admittance to the gate of the School Certificate, but that is not quite the same thing. It is undesirable that any boy should leave school without an acquaintance with the main facts of all three, and this is essential to the specialist in science.

The course in general physics outlined by the University of London provides an opportunity for a wider study of physics in the elementary stages, and is suitable for both classes of candidates. Experienced schoolmasters have already found that boys who have passed in the general physics paper are better equipped for an advanced course in science than those who have followed a more intensive course in one branch of physics only. The mathematical difficulties of such matters as lenses and specific heats are not formidable to older students who have made some progress with their mathematics, and if the earlier work is based on

sound teaching of facts and the exact meaning of words, the theory can follow later with greater appreciation.

For such an early course Mr. Hadley's book is eminently suitable. The author's name is a sufficient guarantee of its soundness to those who know his other books. The illustrations are good and for the most part new, and the number of modern appliances described and explained is remarkable. Some attention has been given to the historical side; but among the great names which appear in the index in thick type we have been unable to find Kelvin, Clerk Maxwell, and J. J. Thomson, although wireless telegraphy and atomic structure are treated with some fulness.

Hyper and Ornate Magic Squares, 15th and 16th Orders. Constructed by Major J. C. Burnett. Pp. 36. (Grantham, Lincs.: The Author, Barkston, 1924.)

MAGIC SQUARES having certain properties were known to the ancients. In modern times they have been studied by mathematicians since Albrecht Dürer's celebrated magic square picture of 1514. A magic square of order n involves in its cells the first n^2 natural numbers in such manner that the sum of the numbers in each row, column and diagonal is the same. Certain of these termed "pandiagonals" introduce the broken diagonals possessing the same additive property. If also every pair of numbers equidistant in a straight line from the centre have the constant sum n^2+1, the squares are further specified as associated or symmetrical. Squares are said to be doubly magic if the properties held show the numbers are replaced by their squares. Again, prime numbers exclusively and the knight's path, etc., have been introduced and the squares, to some extent, studied.

Major Burnett presents in his booklet examples of some of these of the 15th and 16th orders. The last square that he gives is doubly magic of the order 8. They will be of service to those who are interested in the subject. There is an extensive literature. Ahrens deals with it in Chaps. xii. and xiii. of his second volume ("Mathematische Unterhaltungen und Spiele," Bands I., II. B. G. Teubner, Leipzig, 1918), and at the end of the volume gives no fewer than 182 references. W. R. Rouse Ball ("Mathematical Recreations") gives an interesting account and many references. Squares which possess row and column properties without any restriction upon the magnitudes of the cell numbers have also been studied. The theory of these is fairly complete since it has been shown that a syzygetic scheme indicating ground forms and syzygies can be constructed. The allied theory of the Latin Square of Euler has also been connected with the theory of differential operations.

It is much to be desired that some competent person should take up (say) the bibliography of Ahrens and give a good account of the present state of knowledge concerning the various natures of magic squares. This will take time and will involve a book of a fair size; but it ought to be undertaken, because the subject is no longer isolated from other parts of mathematics. Several substantial links have been forged during the last thirty years, and without question others are in prospect. P. A. M.

Bristol Geology and Geography: for the Use of School Teachers and Others. By Prof. Sidney H. Reynolds. Pp. 98. (Bristol and London: J. W. Arrowsmith, Ltd., 1924.) 2s. net.

BRISTOL is situated in a district rich in interest to the geologist and one which is well adapted to the study of physical geography. This little handbook has been produced by its author specially to meet the needs of teachers and students of geography and others whose interest in geology is only general. To this end the use of unfamiliar geological terms has been avoided, so far as possible, and, in addition, a glossary is provided.

The district described extends over a somewhat wider area than might be inferred from the title, and includes most parts of Gloucester and Somerset lying east of the Severn, up to within about 25 miles of Bristol, and takes in a little of Wiltshire. Prof. C. Lloyd Morgan's stimulating introduction to Reynolds' "Geological Excursion Handbook for the Bristol District," which outlines the historical and physical geology of the country surrounding Bristol, is reprinted in the book under notice.

Prof. Reynolds, after tabulating the geological strata and chief features of general interest in the district as a whole, proceeds to describe fourteen smaller physically or stratigraphically separable areas.

Detailed geological information, such as is given in the author's "Excursion Handbook," has, for the most part, been omitted, nor are there any references to previous literature. Prominence is given to the physical characteristics of each area, and the reader is assisted by a number of simple sketch maps and diagrams. A novel section of the book is that describing points of geological interest visible from a railway compartment to travellers in the vicinity of Bristol.

Prof. Reynolds' new handbook should serve its limited purpose very well, and may be recommended to visitors to Bristol, by whom it should be studied in conjunction with the geological model of the Bristol district on exhibition at the Museum there. "Bristol Geology and Geography," however, cannot, as its author points out, replace the "Excursion Handbook" as a guide in the field. V. A. E.

Flora of the Presidency of Madras. By J. S. Gamble. Part 6: *Scrophulariaceæ* to *Plantaginaceæ*. (Published under the authority of the Secretary of State for India in Council.) Pp. ii+963-1160. (London: Adlard and Son and West Newman, Ltd., 1924.) 10s. net.

THE feature of the present contribution to the Madras flora is undoubtedly the account of the Acanthaceæ, which occupies more than a third of the entire part. To most workers this family has been one of considerable perplexity, which has not been lessened by the use some recent authors have made in the classification of the genera of minute pollen characters. It is just this that will make the field-worker of S. India, for whom indeed the flora is chiefly written, grateful to Mr. Gamble for giving him a clear analysis of the family which does not necessitate the use of a compound microscope. The excellent keys of some of the larger genera are also improved by the addition of rather full specific details.

One of the most interesting genera treated of is Strobilanthes. So long ago as 1888 the author published in the *Indian Forester* a special study of the genus and an account of the curious periodic flowering of many of the species. Even in the condensed letterpress of this work, room has been found for brief details of this phenomenon. We learn, for example, that a gregarious shrub like *Strobilanthes Kunthianus* grows in such continuous masses on the grassy downs of the Nilgiris and other neighbouring hills that, when it all comes into flower together about every six years, it covers large tracts with blue. It is believed, indeed, by some that the name of that famous range was derived from this circumstance. Some of the other species have even a longer period of flowerless growth; *S. consanguineus*, for example, probably flowers only at intervals of twelve years.

Another family which shows evidence of a great deal of useful work is the Labiatæ, and near the beginning of this part is a valuable contribution to S. Indian botany in the treatment of the genus Utricularia.

La structure des cristaux: déterminée au moyen des rayons X. Par Prof. Ch. Mauguin. (Recueil des Conférences-Rapports de documentation sur la Physique. Vol. 6, 1re Série, Conférences 14, 15, 16. Édité par la Société *Journal de Physique*.) Pp. 281. (Paris: Les Presses Universitaires de France, 1924.) 20 francs.

THIS is an excellent introductory treatise describing the methods of X-ray crystal analysis and the results which have been obtained. A difficulty in the presentation of our new knowledge of crystal structure is due to the fact that we all dislike being asked to think in three dimensions. Prof. Mauguin has realised this, and provides numerous illustrations, many of them very ingenious, which force the reader to visualise the structures which are described. The book is well planned and deals thoroughly with the subject, while yet being concise. The student will find a short introduction to the geometry of space lattices which provides the necessary foundation for a study of crystal structure. The different methods of analysis are illustrated by examples of the more simple crystals. Three short chapters are devoted to atomic dimensions, the structure of the atom, and the interatomic forces, and a final chapter to a description of the principal types of crystals.

Prof. Mauguin has contented himself with a very brief reference to the more speculative aspects of the new science; a list of papers at the end of each chapter will aid the reader who wishes to pursue the subject further. The lucidity of the style makes the book easy to read, and it is a valuable addition to the literature on the subject.

Dairy Farming Projects. By Prof. Carl Edwin Ladd. (Macmillan Agricultural Project Series.) Pp. xix +327. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1923.) 7*s.* 6*d.* net.

THERE are many novel features in this volume which, although it applies to American conditions, still contains such an amount of information and suggestion that it cannot fail to be of great value to the teacher or student of dairy farming, and ought also to be of considerable interest to any farmer or owner of dairy stock. The whole field of dairy farming is covered: types of cattle; breeding, feeding, and management; methods of arranging and working the farm; business and financial aspects of dairy farming, even to suggestions for advertising stock and produce. There are also chapters on the diseases of dairy cattle, clean milk production, preservation of manure, etc., the whole being arranged under appropriate months from September to June.

It is perhaps doubtful whether the somewhat elaborate course of study which the author maps out could be worked in its entirety, but there is no question as to the educational value of what he proposes, and the ideas and methods could by slight adaptation be made to apply to any country.

The Vegetable Proteins. By Dr. T. B. Osborne. (Monographs on Biochemistry.) Second edition. Pp. xiii+154. (London: Longmans, Green and Co., 1924.) 9*s.* net.

A NEW edition of this well-known work has now appeared. While it contains all the essential material of the first edition, it has been largely rewritten and considerably amplified. The chapter on the proteins of green plants is brought up-to-date by details of Chibnall's work on leaf proteins. The new volume also contains a chapter by L. J. Henderson on the relation of proteins to acids and bases. This discusses the titration curves of vegetable proteins in an extremely lucid manner and presents an interesting addition to the literature of the subject. Frankel's work on the rate of hydrolysis of plant proteins is cited at length in the chapter on the products of hydrolysis, and recent work dealing with the subjects discussed in the original edition appears to be included throughout in sufficiently detailed manner.

The Philosophical Writings of Richard Burthogge. Edited with Introduction and Notes by Margaret W. Landes. Pp. xxiv+245. (Chicago and London: The Open Court Publishing Co., 1921.) 10*s.* net.

RICHARD BURTHOGGE (1638–1698) was an English medical practitioner who, with the exception of an early medical tract in Latin, "Disputatio de Lithiasi et Calculo," wrote entirely on philosophical and theological subjects. The chief of his works, "An Essay upon Reason and the Nature of Spirits" (1694), is interesting for the light it throws on the general state of philosophical opinion in England at the time when Locke's Essay appeared. The present work is not a reprint of any one of Burthogge's writings but a selection from several, accompanied by notes and collated facts concerning extant editions.

Le Principe constitutif de la Nature organique. Par Édouard Jung. (Bibliothèque de Philosophie Contemporaine.) Pp. 694. (Paris: Félix Alcan, 1923.) 30 francs net.

THIS large treatise seeks to bring under one comprehensive and constitutive principle the whole scheme of the conscious life from its basis in physiology and evolutionary biology to its manifestation in cognitive, moral, and æsthetic activity. It is mainly founded on the philosophy of Kant, and is an application of the logical categories and the Kantian method generally to the whole modern scientific biological problem.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Word "Scientist" or its Substitute.

I HAVE long thought that it is desirable, but perhaps not possible, to control the use of the words "science" and "art" and derivatives from them. The popular tendency is to make rubbish both of the original words and of the adjectives derived from them. Thus "science" is definitely used to describe the skill of the boxer, the text of Aristotle's writings, the highest mathematics, the twaddle of Mrs. Eddy, and the elements of chemistry.

In hopeless effort to define science it used (a hundred years ago) to be asserted that every art is based on a science and every science has its related art—a piece of glib and baseless assertion. It is Cicero, I believe, who says "*Scientiæ mentis artes*," the sciences are the arts of the mind, whatever "arts" may be. The French speak of "les Sciences," including therein all the "'ologies." In England we like to make-believe in an obscure essence or pervading entity which we call (when we are journalists) "Science" with a large S. Probably the historic and most luminous use of the word "science" is that in the plural, as in "l'Academie des Sciences." The British Association is for the advancement of *science*, not sciences, as it should be, whilst the Royal Society did not three hundred years ago use that word, but declared that it aimed at the promotion of "natural knowledge"—that is, knowledge of Nature, as distinguished from human tradition and Divine revelation.

We get some glimpse of a synonym for the word science when we find Cicero writing "*Physiologia naturæ ratio*," which must be translated "Physiology, the ratio (or 'reasoned story') of Nature." All the "'ologies" or branches of science are ratios or reasoned stories of those sciences. But I can find no word which will serve to distinguish one who deals with many branches of science or to name a body of men dealing with many distinct sciences. It is easy to name those who take up this or that science, as geologist, phytologist, zoologist, chemiologist (chemist), electrologist (electrician), etc. But we soon get into a muddle, even here, since words derived from φύσις have been insanely perverted in meaning during the past three hundred years—for example, *physic* and *physics*, *physicien* and *physician*, as well as *physiology* (this last to mean *not* "natural history," as it should, but the study of the activities of the organs of animals and plants).

I hope NATURE will continue to refuse to use the word "scientist." Its formation can be defended, it is true, as parallel to that of "artist." But the example of the word "artist" gives us no encouragement, for it is the most vague and ill-used word in our language. All sorts of mysterious qualities are claimed for "the artist," and any impostor can defend his claim to be "an artist," and to worship art with a big A. We shall have others saying they "stand for" science with a big S and calling each other "Scientist." The eminent scientist Barney Bunkum is already flourishing in the United States and in English newspapers. I think *we* must be content to be anatomists, zoologists, geologists, electricians, engineers, mathematicians, naturalists (that last is a term I like and wish to use). We cannot find a name to join all the followers of different branches of science, but I think that "rationalist" rightly designates those who, in their inquiries into the unknown in whatever field, strictly follow the scientific method.

It is well to remember in this connexion what Clifford wrote in one of his essays: "There are no scientific subjects. The subject of science is the human universe—that is to say, everything that is, or has been, or may be related to man."

What then *can* we mean by calling a man a scientist? We cannot mean that he studies or pursues any *special* subject. Every subject can be the subject of science. "Science" and "scientific," of course, have reference to the method and habit of mind. Our "man of science" is a man who makes use of and cultivates a special habit of mind or method which is known as the scientific method or experimental method. Assuredly this is *not* what the journalist means when he calls a person "an eminent scientist."

In old times the word "philosopher" was quite properly used for those we now call men of science: they were called "philosophers" or sometimes "natural philosophers," but custom—the most absurd jade we tolerate—actually nowadays restricts "philosophy" to speculations about metaphysics. Hamlet's "philosophy" was wider and all-embracing. The founders of the Royal Society called themselves "Philosophers." I am afraid that word will not do, to-day, for what is wanted; and I feel pretty sure there is not one which will. I should call myself alternatively a philosopher, a natural philosopher, a naturalist, or a rationalist. Rationalist is really the best designation. All men of science are rationalists, but many shrink with fear from the word, since they have been told that the devil himself is a rationalist. It is, however, a just and honourable title. On the other hand, "scientist" has acquired—perhaps unjustly—the significance of a charlatan's device.

E. RAY LANKESTER.

44 Oakley Street,
Chelsea, S.W.3.

IN my little book on "Notes on the Composition of Scientific Papers" I have defended the use of "scientist": it is quite a normal word, such as artist, economist, etc. Against it is the dislike of all new words or spellings; they are contrary to our habits. But there is more than this: in England (especially as compared with Germany or Scotland) there has been a certain prejudice against science as a *profession*. Many of our great men (*e.g.* Darwin, Rayleigh, Clerk Maxwell, etc.) have been great amateurs; and the generations bred upon letters only (*e.g.* Swift) have regarded science as too arid for exclusive culture. The amateur is saved from being narrow or inhuman. So there has been an unconscious antipathy to science as a calling or profession. But I am speaking of our prejudices—remnants of the past—which now are cobwebs, and no more. I should accept the word were I in your place. NATURE has set a good example in another very important—far more important—linguistic matter, namely, the use of "*fact*" as distinct from opinion, or inference, or axiom, or principle, or truth, etc., in the sense of general statement founded upon (assumed) facts. We collect our facts, and upon them are built fallible conclusions or laws, which not a few contributors call also "*facts*." We must keep the word fact for the several events, and call our inferences opinions, conjectures, hypotheses, etc., and ultimately, when relatively certain, theories; theory is our highest scientific category. To mistake inferences or axioms for facts has been a curse of science.

CLIFFORD ALLBUTT.

St. Radegund's, Cambridge.

THE "Oxford Dictionary" defines *scientist* simply as "A man of science." It defines *man of science* (*s.v.* Science, 6) as: *a* (a sense ruled out as obsolete); *b*, "In modern use, a man who has expert knowledge of some branch of science (usually, of physical or natural science), and devotes himself to its investigation." All this with no suggestion whatever that the usage is blameworthy or questionable, or that there is any other modern acceptation.

Accordingly, in the "Pocket Oxford Dictionary" published this year, the only definition of *scientist* given is "(esp.) person learned in one or more of the natural sciences," in which "(esp.)" merely indicates that the limitation to the natural sciences is, though usual, not so far obligatory that, *e.g.*, a pure mathematician might not, exceptionally, be called a scientist.

My opinion is, then, that to refuse the word the now prevalent and extremely convenient sense that you mention, "a worker in the field of physical or biological science," is antiquated pedantry. I may add that nothing is gained by the substitution of *man of science*, so far as meaning is concerned; for any undesirable vagueness that may attach to *scientist* comes to it only as a consequence of *science's* having also more than one sense. But I suspect that those who really have an instinctive (as opposed to a merely imitative) aversion to this use of *scientist* are influenced not by doubts of its meaning, but by dislike of its (and many other -ist words') slightly abnormal formation; but that is not the point raised in your question. H. W. FOWLER.

Moulin de Haut, Guernsey.

So long ago as 1840, according to the "Oxford Dictionary," Dr. Whewell, eminent as man of letters as well as man of science, wrote: "We need very much a name to describe a cultivator of science in general. I should incline to call him a Scientist." I do not think the objections to the word on merely literary or linguistic grounds can be maintained. It is a hybrid, but the language is full of hybrids: moreover, it may well be argued that *-ist* is naturalised as an English termination.

There is, however, another sort of objection which has to be weighed. Like other words in *-ist*, it has a professional air, as if the man who so described himself were claiming an *ex cathedra* authority for his utterances. Hence its use is not always complimentary. We see this in its derivatives "scientism" and "scientistic." Similarly, when I have been introduced to a public meeting as an "educationist" or "educationalist," I have wished to be saved from my friends: I would rather be called a schoolmaster. My conclusion is that the term scientist is too convenient to be wholly rejected, but that writers would do well to remember its less complimentary use as a label, and not resort to it too frequently.

J. H. FOWLER.

16 Canynge Square, Clifton, Bristol.

THE word "scientist" is, in itself, neither better nor worse than dentist, oculist, socialist, or violinist. It would be pedantic, at the present day, to object to it merely on the ground that it begins in one language and ends in another. If it were a new word, introduced for the sake of brevity and convenience by some respectable writer, I should have little objection to it; I should be reluctant to use it myself, but I should not dream of objecting to its use by others.

It seems to me, however, that the word has already got a sort of taint about it, very much as the word "sophist" did in Greek. It is often used in an equivocal, or even disparaging, sense, by people who have no great respect either for science or the "scientist." Most men of science would surely rather be called so than be dubbed scientist. The widely used term "Christian Scientist" has helped to make matters worse; what that phrase means I do not know, but if I did know I am sure I should not like it any the better.

On the whole, I take it that the word scientist has been in low company, and I should be very slow to introduce it into better.

D'ARCY W. THOMPSON.

St. Andrews.

REGARDING the inquiry contained in your letter, I would say that the word "scientist" has fully established itself in the written and spoken language of scientific workers as well as of non-scientific persons. It is, of course, when one stays to examine it, a hybrid, but like that other hybrid, the mule, it does useful work. After all, there are numbers of hybrid words in our language also doing useful work, and one does not now trouble to look them in the mouth. For example, take the Latin stems with the Greek termination *-ist*. The psychologists do not blush to use the word "animist"; they even say "behaviourist." In my opinion, "scientist" is a gentle-born word alongside of "behaviourist," which may well have besmirched the pages of NATURE.

W. J. SEDGEFIELD.

The University, Manchester.

I HAVE submitted your inquiry to my son, who is a literary critic. He sees no objection to "scientist," and is rather surprised that it has not been adopted before. He thinks it as well-formed as "artist." He does not much like words ending in "ist," but concludes that they cannot be avoided.

For myself, I dislike the word, but cannot give a clear reason for the dislike—unless it be that the preposterous term "Christian" prefixed to it has given it an alien significance. On the whole, I feel that the public has forced the word upon us, and that we must succumb. OLIVER LODGE.

Normanton House,
Lake, Salisbury.

PERSONALLY, I should say "man of science" rather than "scientist"; but I do not think one can deny to the word scientist its legitimate place in English. It is recorded in the "Oxford Dictionary," together, I admit, with a good many words which a man does not use if he can help it. But the place of "scientist" in the English vocabulary must have been fairly safe since Whewell wrote in 1840, "We need very much a name to describe a cultivator of science in general. I should incline to call him a Scientist."

R. W. CHAMBERS.

University College,
Gower Street, W.C.

IN spite of the objections which have been raised to the use of the word "scientist," it may with advantage be used in place of "scientific worker" or "man of science." Whewell seems to have coined the word to describe "a cultivator of science in general." On the whole, there is much to be said in favour of it. It should not, however, in my opinion, be limited to a worker in the field of physical or biological science. ISRAEL GOLLANCZ.

King's College, London.

My intense dislike of the word "scientist" is due to the fact that it debases the currency. The word is not applied to a man to indicate respect for his scientific or philosophical attainments, but to indicate a certain disdainful attitude towards the truth claims of æsthetic, moral, and religious values. The distinction so often expressed between philosophers and scientists is a false one when it implies (and it is meant to imply) that philosophers are uninterested in or indifferent to the positive results of science.

H. WILDON CARR.

107 Church Street,
Chelsea, S.W.3.

The Biology of Verse.

IN NATURE for October 11, 1924, p. 534, I have reported the results of the only registrations of verse ever made and analysed. They show that verse is a current of speech energy of varying amount so adjusted as to come in more or less regular waves. When the centroids of these waves are calculated, they are found to occur at approximately equal periods.

The next problem is that of the source of this current of energy. The replies of many living poets to a question-paper agree without exception with all the statements I have been able to find from the poets of the past: they have no ideas whatever on the subject. They all assert, moreover, that the verse-form comes to them ready-made along with the poetic content. This poetic content, they all declare, is forced upon them by some inner power. The source of verse, therefore, must be sought in the source of poetry.

The poets all agree that the source of their poetry lies entirely outside of their consciousness. In psychological terms it is a product of the unconscious. In physiological terms it is a product of bodily processes that result in producing poetical feeling and ideas in consciousness. In either sense it is a biological phenomenon of which the ultimate explanation must be in biological terms.

On the psychological side there are the statements of famous poets of the past. Many say that they write because they must (Pope, Goethe, Schiller, Grillparzer, Hebbel, Brentano, and so on). One of them says that whenever a new poetical idea struck him he had to write it down even at the cost of his life. They often write in over-excited or half-conscious conditions (Goethe, etc.). They write to relieve themselves from mental strain or trouble (*e.g.* Byron). They write out their own inner selves (Byron, Goethe, Schiller, Hebbel). They write because they feel themselves mentally ill (Grillparzer, Heine). They write because they feel themselves to be criminals in need of confession (Hebbel, Ibsen). A poet is a lunatic (Shakespeare). Poetry flows from the poet like gum from a tree (Shakespeare). The statements that I have collected from living poets are along the same lines.

Further psychological information is furnished by the work of Freud and his gifted disciple, Otto Rank. Poetry is the result of an inner conflict. On one side is the fundamental part of the Unconscious, the "It," with its one impulse to have its own inflexible way and to obtain peace; on the other side is the Self, or the "I," with the wish to live, love, and enjoy by adapting itself to the environment. Out of the struggle there is engendered the Conscience, a kind of council of the League of Nations that sits in judgment over the self. Again, like the League of Nations, it is controlled by the stronger powers of the "It" and has the one function of condemning the weaker "I." At the instigation of the "It," Conscience takes every opportunity of declaring the "I" to be a criminal worthy only of annihilation and death. It is kept from doing so only by the power of the Self to resist it. The details of this conflict must be sought in the works of Otto Rank.

The result of the conflict depends on the amount of fundamental energy, or kinetic drive, at the disposal of the Self. When this becomes small, as in misfortune, weakness, illness, or grief, the Self can no longer resist the efforts of "It" to get Conscience to pass a condemnation of the Self to some degree of death varying from withdrawal from social life to suicide. With more fundamental energy the Self struggles with varying success but never gets real control; this produces the condition of the neurasthenic failure. With a larger amount of fundamental energy the result depends on what compromise can be effected. Sometimes the Self compromises with the "It" by carrying out some of its anti-social demands; this produces the criminal. Sometimes the Self can win only by denying the truths of the environment; this produces the lunatic. Sometimes the Self can escape by affording the "It" a means of letting off its force in a way that partially lightens the pressure but yet does not bring the Self into conflict with the environment. This produces the class to which the poet belongs.

Poetry is thus the expression of the impulses of the "It" in a form acceptable to the environment. These impulses are familiar to Freudian analysts. Some of them have been exhaustively treated by Otto Rank. A complete general treatment of the poetic conflict has not yet been made.

It is my own belief, however, that this conflict can be reduced to biological terms that can even be measured. In NATURE for March 15, 1924, p. 386, I have shown that records of speech show the presence of three biological forces; the impulse to conform to the speech of the environment, the hindrance to successful conformity, and the impulse to correct the resulting defect. The three forces correspond quite well to the Freudian concept of the Self, the "It," and Conscience. In many speech records—both normal and pathological—the prevalence of one or another of these forces can be plainly seen and measured. It is a commonplace of my laboratory to use the size of the probable error in making speech sounds as a measure of the successful adaptation of the speaker to his social environment. A large probable error indicates either an increase of the inner hindrance to adaptation or a decrease in the impulse to correction—or in Freudian terms either an increase in the power of the "It," or a decrease in the force of the Self or a decrease in the power of Conscience. Quite characteristic is the fact that a very large probable error is diagnostic of general paralysis, a disease the earliest characteristic of which is a decay of the social sense, that is, of Conscience.

Whether the result of this conflict depends on metabolism or the presence or removal of toxins in the blood or on the hormone balance, biochemistry must determine. It is my belief that a physiological explanation quite parallel to the psychological one can be found.

In any case poetry is the product of a compromise among biological forces whereby the social force is strong enough to affect the adjustment by allowing the anti-social force some degree of expression.

The source of the verse form itself is now clear. Rhythmic speech is the primitive form of language. The linguist Prof. Jespersen of Copenhagen agrees with the poet that

> Thus Nature drove; warbling rose
> Man's voice in verse before he spoke in prose.

OEHLENSCHLÄGER.

The natural speech expression of the more primitive savage Unconscious is in verse form. That is why, as so many poets report, their poems come to them suddenly in completely finished form (Goethe, Grillparzer, Hebbel, Brentano, Fontane, Goncourt, Flaubert, and many living poets). The source of the verse form thus lies, like the source of poetry, in a partial yielding of the Self to the demands of the Unconscious for expression.

E. W. SCRIPTURE.

University of Vienna.

Experiments on Sex in Mushrooms and Toadstools.

MISS MOUNCE,[1] working under my direction, found that *Coprinus sterquilinus*, *C. stercorarius* (a sclerotium-producing species), and *C. narcoticus* are all homothallic. All the spores in each of these species are sexually of one kind, and each spore gives rise to a mycelium which becomes diploid and fruits perfectly without fusion with any other mycelium.

Hans Kniep[2] has shown that in *Schizophyllum commune* and *Aleurodiscus polygonius*, segregation in the basidium results in the production of four sexually different haploid genotypes, so that the spores sexually are of four different kinds. Normally one kind can react with only one of the others. Two Mendelian pairs of factors are involved. The diploid fusion nucleus in the basidium bears both pairs of factors and may be represented as (AaBb). The haploid nucleus of each of the four spores bears only one of each pair of factors, so that sexually the four kinds of spores may be represented as (AB), (Ab), (aB), and (ab).

W. F. Hanna,[3] working in my laboratory upon *Coprinus lagopus*, has confirmed Kniep's results. His experiments, which have involved some 1500 matings, clearly demonstrate that, here again, we have a species which bears spores which sexually are of four different kinds: (AB), (Ab), (aB), and (ab).

There has just come into my hands a paper by Vandendries,[4] in which he records experiments which prove that *Coprinus radians* is bisexual, *i.e.* that this fungus produces spores which fall into two sexually opposite groups, and not into four groups as found by Kniep for *Schizophyllum commune* and *Aleurodiscus polygonius* and by Hanna for *Coprinus lagopus*.

Miss Dorothy Newton,[5] who has been studying the problem of sex in my laboratory for upwards of a year, has obtained results with *Coprinus Rostrupianus* which are exactly similar to those Vandendries obtained with *C. radians*; for, as a result of upwards of 400 matings, she has found that in *C. Rostrupianus* the spores fall into only two groups which are sexually opposite.

In *Aleurodiscus polygonius*, under certain abnormal moisture conditions, the four spores of each basidium are shot away together in a single mass. Kniep[6] noted this fact and took advantage of it to analyse the sexual reactions of the four spores on each of thirty-five basidia. He found that each basidium bore two kinds of spores, two of one sex and two of another, and that there were two kinds of basidia, so that the two pairs of spores of one group of basidia were different sexually to the two pairs of spores of the other group of basidia. The four spores of one group may be represented as (AB), (AB), (ab) and (ab), and the four spores of the other group as (Ab), (Ab), (aB) and (aB).

Kniep's method of obtaining the four spores of a single basidium and separating them by shaking them apart in agar is applicable, so far as is at present known, only to *Aleurodiscus polygonius*; and Vandendries was unable to analyse the sexual reactions of the four spores of a single basidium of his *Coprinus radians*.

A method for removing the four spores of a single basidium and sowing them separately has been devised in my laboratory, and it has the advantage over the method used by Kniep in that it is not dependent on an abnormality but is generally applicable to normal fruit-bodies of Coprini and other Hymenomycetes.[7] The method is as follows. A gill is placed on a slide and a cover-glass is lowered down upon it and pressed gently against the hymenium. The cover-glass is then raised, inverted, and examined under the microscope. The four spores of each of a number of basidia are then seen to be attached by their apices to the cover-glass, so as to form tetrads resembling those which may be observed on isolated basidia when one looks down on a gill from above with the microscope. Using the dry-needle method, described by Hanna,[8] it is then not difficult to remove the other spores around a perfect tetrad and afterwards to pick up the four spores of the tetrad one by one and sow them individually in hanging drops of a culture medium.

By employing the methods just described, both Hanna and Miss Newton have successfully analysed the sexual reactions of the four spores of a considerable number of individual basidia. In Hanna's quadrisexual species, *Coprinus lagopus*, some of the basidia were found to bear spores of two kinds only, a pair of one sex and a pair of another and opposite sex, while other basidia were found to bear spores of all four kinds: (AB), (Ab), (aB), and (ab). The occurrence of four different kinds of spores on a single basidium proves that the reduction process in the basidium takes place with the second division of the nucleus, and not with the first as found by Kniep in the case of *Aleurodiscus polygonius*. In Miss Newton's bi-sexual species, *Coprinus Rostrupianus*, all the basidia have been found to be exactly alike, for they all bear only two kinds of spores, two of one sex and two of the other and opposite sex.

Negative and Doubly Charged Positive Ions in Argon.

IN letters to NATURE (June 16, 1923, and July 26, 1924), and elsewhere (Proc. Roy. Soc. A, vols. 102, 104, 105), Dr. H. D. Smyth has described investigations he has made of the ionisation of several diatomic gases. By using positive ray analysis he was able to correlate different ionisation potentials with the production of ions of different ratio of mass to charge. I have now used the same apparatus to study the ionisation of argon, chiefly to explain, if possible, the "blue" spectrum of this element.

From a preliminary analysis of results I found that singly charged, positive, atomic argon ions were first produced in detectable numbers when an accelerating potential of about 17 volts (uncorrected) was applied to electrons striking the atoms. I do not consider that the accuracy of the determination is sufficient to distinguish between the varying results of other observers.

Doubly charged, positive atomic ions were not produced at all until an accelerating potential of more than about 45 volts was applied. For the most part these must have been produced by single impacts as the pressures and thermionic currents used were so small as to make successive impacts very improbable. This result is contrary to the assumption that the critical potential of about 34 volts at which the first part of the blue spectrum appears (Horton and Davies, Proc. Roy. Soc. A, 102, p. 131 (1922), and Déjardin, *Ann. de Phys.*, 10th Series, v. ii., p. 241 (1924)) corresponds to the production of doubly charged ions. Therefore this portion of the blue spectrum cannot be the entire first enhanced spectrum of argon. It may be due to excitation of the singly ionised atom, but the detailed application of this hypothesis meets difficulties which are too complicated to discuss here.

I also found that large quantities of negative ions could be produced. These apparently originated in a region of the tube where impacting electrons had just sufficient energy to excite the atoms. It therefore appears that in argon it is a necessary and sufficient condition for the capture of an electron that the atom first be in an excited state.

A full report of this work is to be published shortly.

Flow of Sap in Trees.

IN recent discussions on the upward movement of sap in trees, I have seen no mention of an interesting observation of Charles Darwin to be found in his "Voyage of the Beagle" (p. 258, John Murray, 1912 edition). He was exploring the Campana or Bell Mountain about 26 miles from Valparaiso, and he writes as follows, for the quotation is worthy to be reprinted in full :

"In a few places there were palms, and I was surprised to see one at an elevation of at least 4500 feet. These palms are, for their family, ugly trees. Their stem is very large, and of a curious form, being thicker in the middle than at the base or top. They are excessively numerous in some parts of Chile, and valuable on account of a sort of treacle made from the sap. On one estate near Petorca they tried to count them, but failed, after having numbered several hundred thousand. Every year in the early spring, in August, very many are cut down, and when the trunk is lying on the ground the crown of leaves is lopped off. The sap then immediately begins to flow from the upper end, and continues so doing for some months ; it is, however, necessary that a thin slice should be shaved off from that end every morning, so as to expose a fresh surface. A good tree will give ninety gallons, and all this must have been contained in the vessels of the apparently dry trunk. It is said that the sap flows much more quickly on those days when the sun is powerful ; and likewise, that it is absolutely necessary to take care, in cutting down the tree, that it should fall with its head upwards on the side of the hill ; for if it falls down the slope, scarcely any sap will flow ; although in that case one would have thought that the action would have been aided, instead of checked, by the force of gravity. The sap is concentrated by boiling, and is then called treacle, which it very much resembles in taste."

The effect of the sun and the great quantity of sap from a felled tree are both noteworthy, but the effect, or rather inhibition, due to gravitation, adds mystery to an obscure subject. A friend has proposed to test this gravitational effect with two young felled sugar maples next spring.

The Colour of Sulphur Suspensions.

IN the review of Ostwald's "Licht und Farbe in Kolloiden" which appeared in NATURE of November 8, p. 672, the reviewer alludes to the investigations of Keen and Porter on "sulphur suspensions containing particles *large compared with wave-lengths* and indigo in *transmitted light.*" He adds, "No theory of this phenomenon is available so far ; until one is found there will be a distinct gap in the optics of disperse systems."

A theory of the effect observed by Keen and Porter was given by Prof. C. V. Raman and Mr. B. Ray in 1922 ("On the Transmission Colours of Sulphur Suspensions," Proc. Roy. Soc. A, vol. c., pp. 102-109), the explanation offered being that the colour of the transmitted light is due to interference between the primary wave and the light scattered by the particles in the direction of the primary wave. Results were given of calculations based on Rayleigh's theory of the scattering of light by a transparent sphere.

Raman and Ray repeated Keen and Porter's experiments and found that the diameter of the sulphur particles when the indigo colour first appeared was considerably less than that quoted by Keen and Porter, but that the amended value agreed satisfactorily with the theory. The theory appears to be adequate, although the computation of numerical results is extremely tedious. A more complete comparison of theoretical with experimental results than has yet been published is desirable.

Absorption Spectra of Mixed Metallic Vapours.

DURING work on the absorption spectra of mixtures of metallic vapours, I have obtained band spectra peculiar to mixtures of magnesium and alkali metals, and also to mixtures of calcium and alkali metals. A sodium-potassium band spectrum has already been described (Proc. Roy. Soc., 1924). The existence of such band spectra is of interest, as it points to the presence of molecules of volatile alloys of these metals in the mixed vapours.

I have incidentally observed that lines of the series $1S - md$ are developed in the absorption spectra of rubidium and cæsium vapours. As has been remarked by Datta, who observed the corresponding absorption in potassium, the development of such series in the absence of an electric field is a contravention of the selection principle, since it involves a change of two in the azimuthal quantum number.

I have, further, been unable to trace any previous observation of the cæsium series $1S - md$, either in emission or absorption, and wave-length measurements, as well as experiments upon the conditions necessary for its appearance, are at present in progress.

The Ages and Masses of the Stars.

By J. H. JEANS, Sec. R.S.

AS is well-known, a rapidly moving electron has a greater mass than a stationary one; more force is required to deflect it from its path or to produce a specified acceleration. The theory of relativity shows that this is not an isolated phenomenon, but an example of a universal principle. Every natural system, on acquiring additional energy E increases its mass by E/C^2, and a loss of energy causes a corresponding loss of mass.[1] For example the sun, losing energy by radiation at the rate of $3{\cdot}8 \times 10^{33}$ ergs per second, must be losing mass at the rate of $4{\cdot}2 \times 10^{12}$ grammes (about four million tons) a second.

Changes of energy and changes of mass are, then, the same thing: it is immaterial whether we specify the change in terms of energy or of mass. It is a somewhat different question whether absolute mass can be specified as absolute energy or vice versa. For example, setting an electron in motion with a velocity $0{\cdot}866C$ doubles its mass, but in what sense does it double its energy? If m was the mass of the electron when at rest, the addition m to its mass has represented an addition mC^2 of kinetic energy, but did the original mass m also denote energy mC^2?

Clearly an electron at rest must be thought of as having some energy, for it consists of electric charges which have been brought very close to one another in opposition to their mutual repulsions. If an electron is regarded as a negatively charged sphere, its electrostatic energy is $\frac{3}{4}mC^2$. To satisfy the conservation of energy when the electron is in motion, there must be further energy $\frac{1}{4}mC^2$ of unknown type,[2] making energy mC^2 in all. Presumably the whole of this would be set free if the electron could be persuaded to explode and scatter to infinity.

The energy mC^2 just discussed may be called "sub-electronic" energy, any further energy which electrons may have in virtue of their motion or positions in space being "super-electronic" energy. The two energies become equal when an electron moves with a velocity $0{\cdot}866C$, corresponding to a temperature of 4,000,000,000° Centigrade; for an atom the corresponding temperature is thousands of times higher. In all actual systems, then, the super-electronic energy is insignificant in comparison with the sub-electronic. In the sun the ratio of the two kinds of energies is probably at most of the order of one to a million, and the same is of course true of the two kinds of mass. Of the sun's total mass of 2×10^{33} grammes, not more than about 2×10^{27} grammes can be "super-electronic."

The sun, as we have seen, is radiating mass away at about four million tons per second. The usual estimates of the sun's age have all been based on the supposition that the only mass available for radiation is the "super-electronic" mass. The estimates reached in this way, about twenty million years, have been too short to satisfy either astronomers or geologists. Some years ago I suggested that the source of stellar radiation was to be found in an actual destruction of matter in a star's interior, the mechanism probably being that positive and negative electric charges fell together and annihilated one another. The essential novelty in this suggestion was that it made the enormous "sub-electronic" mass of a star available for radiation, in addition to the comparatively puny "super-electronic" mass; thus it immediately extended our estimate of the sun's life by a factor of the order of a million. Whatever else may be thought of this suggestion, it must be admitted that it solves, with a comfortable margin to spare, the age-long problem of the source of the energy of stellar radiation.

Nothing in the suggestion appears to conflict with modern atomic physics. According to classical electrodynamics, the mutual destructiveness of positive and negative charges was such that all the matter of the universe ought long ago to have melted away in a blaze of glory. The quantum-theory has introduced restrictive forces which, in some way unknown to us, keep positive and negative charges apart, but these forces are not unfailing in their action. At times the electron in the hydrogen atom eludes them and drops down from orbit 3 to orbit 2, at times it drops farther from orbit 2 to orbit 1; let it sometimes also drop from orbit 1 to orbit 0, and what we have been imagining becomes an accomplished fact.

In the form in which we have so far put it, the whole question looks somewhat speculative. It takes on an entirely new complexion in the light of the definite results recently obtained by Eddington (cf. NATURE, May 31, 1924). Both as a matter of theory and of observation, Eddington finds that a star's luminosity is a function, approximately, of its mass alone. All the stars that are about as massive as Sirius have about the same luminosity as Sirius, stars as massive as our sun are about as luminous as our sun, and so on. At present Sirius has 2·5 times the mass of our sun, and 36 times the luminosity. Not having an unlimited store of energy it cannot go on radiating at its present rate for ever; its luminosity must eventually decrease, and some day this will only be equal to that of our present sun. When that day comes, Sirius will be only about as massive as our present sun, so that between now and then it must lose 60 per cent. of its present mass. This is enormously more than the total "super-electronic" mass of Sirius, so that we conclude that the main part of its loss of mass will of necessity be "sub-electronic." Further, we know of no normal process by which mass can escape except by radiation, whence we conclude that the diminution of mass is the equivalent of the energy radiated away.

If this be conceded, Eddington's relation between luminosity and mass fixes quite definitely the rate at which stars change both their luminosity and mass. For example, the sun with a mass of 2×10^{33} grammes, is radiating away $4{\cdot}2 \times 10^{12}$ grammes a second. Thus, after 1,500,000 millions of years its mass will be reduced by 10 per cent., so that from Eddington's table, its luminosity will be reduced by about 30 per cent. In the same way we find that the interval on the evolutionary ladder between Sirius and our sun is approximately $6{\cdot}4 \times 10^{12}$ years. Between a giant sun of ten

[1] Here and throughout C denotes the velocity of light, 3×10^{10} cm. a second.

[2] Jeans, "Electricity and Magnetism," 4th edition, § 667.

times the mass of our sun and our sun, the interval is $7{\cdot}5 \times 10^{12}$ years. These two figures do not differ greatly, for a star squanders its mass at a great rate during its highly luminous giant state; it is the last part of the journey that takes the time. Both figures are of course enormously large in comparison with any estimates heretofore made on the ages of the stars.

If nothing unexpected intervenes in the next $6{\cdot}4 \times 10^{12}$ years—and it must be admitted that there is time enough for the unforeseen to occur—Sirius will at the end of that period be similar to our present sun. We cannot, however, assert that $6{\cdot}4 \times 10^{12}$ years ago our sun was in the state of the present Sirius. The old-fashioned astronomer believes that the whole universe was created only some 10^9 or 10^{10} years ago, and until the contrary is proved he has a right to his opinion.

The geologist insists that life on our earth must have existed for millions of years because fossil bones occur under deposits which, he estimates, must have taken millions of years to accumulate. A similar method of reasoning is available to the cosmogonist, who has the advantage over the geologist that he can calculate, instead of estimating, his periods of time.

All calculations in cosmogony have hitherto been made on the supposition that stellar masses remained constant. The conception of diminishing masses brings new features into almost every problem of cosmogony. For example, the orbit of a particle about a gravitating mass is no longer an endlessly repeated ellipse; it is an ellipse of ever-increasing size, the major axis of which varies inversely as the mass of the attracting body. After 1,500,000 millions of years, when our sun will only have nine-tenths of its present mass, the radius of the earth's orbit will be ten-ninths of its present size and the year will have lengthened to 451 days. The whole universe of stars is expanding for the same reason and in the same way as the solar system. When, if ever, in the past the average star had four times its present mass, the stars must have been 64 times as closely packed as now, and stars must have interfered with their neighbours 64 times as much as they now do. When due allowance has been made for this, it is found that features are shown by the stars which could be produced by the influence of neighbouring stars in periods just about equal to those we have had under consideration, say six or seven millions of millions of years. These features are the fossil bones of cosmogony.

Foremost among such features must be placed the orbits of binary stars. A newly formed binary star has generally a period of a few hours and an almost circular orbit of radius of the order 5×10^{11} cm. Old binaries show much longer periods, orbits which are frequently highly eccentric and of radius much greater than those of new stars. Statistically, the orbits tend towards conformity with what may be called the "equipartition law"—the law which would be obeyed exactly if the binaries were pushed and pulled about by their neighbours for an unlimited time. Calculation shows that the observed partial conformity to this law indicates a knocking about for a period of the order of that just mentioned, say six million million years.

The same period is indicated by the velocities of the stars in space. Statistically, the most massive stars have the lowest velocities, and there is a pronounced tendency to obey an "equipartition law" under which the velocity varies inversely as the square-root of the mass. This would be obeyed perfectly if the stars had influenced one another for ever; the partial extent to which it is obeyed again indicates a period of the order of six million million years.

A somewhat less convincing "fossil-bone" is provided by a study of the ratios of the masses of the two components of binary stars. As a binary gets older, its components become more equal in mass. According to Aitken,[3] 20 spectroscopic binaries of early type (B to B8) show an average mass-ratio 0·70, while 7 of late type (F to G) show an average mass ratio of 0·89. Calculation shows that to pass from a mass-ratio 0·70 to one of 0·89 would require a period of 4·5 million million years. The numerical result is entirely satisfactory, but it must be admitted that it is based on scanty material.

Finally, it may be remarked that the extension of the time scale which is now proposed increases enormously the chance of solar systems being formed by tidal action. With a time scale of 10^9 years, we had to think of systems of planets such as our own as being of necessity extremely rare. With the longer time-scale and the recognition that our system of stars must have been more closely packed in the past than now, we can think of planetary systems as being, if not quite the normal accompaniment of a sun, at least fairly freely distributed in space.

[3] "The Binary Stars," pp. 206, 207.

The Ages of Peat Deposits.

By Dr. W. H. PEARSALL.

RECENT work on the Yorkshire peat has raised some very interesting problems as to the ages of various types of peat deposit in the British Isles. One of the striking features of the Pennine peat is the normal absence of any marked differences in composition, such, for example, as the definite forest layers observed in the Scotch deposits by Prof. Lewis. Typical Pennine peat is usually composed entirely of cotton-grass remains, though here and there the remains of heather or birch point to local desiccation, which can usually be traced to drainage. In the Ingleborough district, Messrs. Cheetham and Burrell find the basal vegetation to differ very slightly from that of the main peat, though rushes are often present. Birch scrub with local pine and oak is also very widely distributed up to 1900 ft. The presence of oak is suggestive, since this tree is not known from deposits older than Neolithic, either in England or Scandinavia.

Mr. J. Holmes first pointed out that neolithic flints occurred about the base of the peat, and now further information is accumulating, largely through the efforts of Mr. F. Buckley and Dr. T. W. Woodhead. They

have found among the trees at the base of the peat, a horn of *Bos primigenius* and a triangular arrow-head of the Neolithic Dolmen period. At a somewhat higher level, a piece of bronze and a barbed arrow-head suggest the Bronze Age horizon. Added to this, are previous discoveries of two horizons in the sand underlying this peat. The lower layers of sand contain flint implements of the Belgian Tardenois culture, while similar traces of the later Tardenois period are found in the upper layers of sand.

If the facts so far ascertained are completely substantiated, they form a very valuable chronological sequence. The question then arises as to their relation to the Scottish peat deposits studied by Lewis. These show fairly definite horizons roughly corresponding to Geikie's well-known climatic periods, namely, from below upwards, a Sub-arctic or Tundra zone, a Lower Forest, a Lower Turbarian or peat layer with some arctic plants in places, an Upper Forest, and finally an Upper Turbarian or deep peat layer.

Now, tree layers in peat are not *necessarily* an indication of climatic change. There is, for example, at present a general tendency for woodlands on poor soils (owing to the progressive leaching of the soil) to be replaced by moorland types of vegetation. Wood layers at the base of the peat may indicate a similar natural succession of vegetation. The study of plant successions on lowland peat also indicates that stages of woodland may alternate with stages in which peat is formed more rapidly, without the intervention of climatic change. It is obvious that extreme caution is necessary in interpreting the wood layers in peat deposits. The validity of the assumption made by Lewis that the Scottish peats show evidence of climatic change, largely rests on two facts. In the first place, the peats studied were mostly from high levels, where the general conditions are unfavourable to tree growth. Secondly, Lewis lays emphasis on the continuity of the main horizons almost all over Scotland. The Scottish wood layers are thus, apparently, signs of widespread changes. Samuelsson has reinvestigated the Scottish deposits and his main conclusions agree with those of Lewis.

So far as it can be ascertained, there is at present little evidence as to the archæological age of the main horizons. We can, however, obtain a rough correlation with the English results by indirect methods. According to Clement Reid, the submerged forests round the English coast are apparently of Neolithic age. Reid also estimated the period of coast depression to occur between 3500 and 1500 B.C., since when the coast has remained fairly stable. He pointed out that as no arctic or tundra species occur in these forests, they were probably formed a long time after the last considerable glaciation. The submerged forests apparently approximate to the tree layer at the base of the Pennine peat and the period of its replacement by moorland. Now along the Scottish coasts, the submerged forests are replaced by the 40-50 foot beaches, also of Neolithic date, and these beaches correspond in time to the Lower Turbarian stage of Lewis. If this approximation is correct, we then obtain the suggestion that the destruction of the Pennine forest coincides with the colder climate assumed for the Lower Turbarian. It would also indicate the Scottish Upper Forest to be approximately Bronze Age, while the Palæolithic horizons might lie below the Lower Forest. It is of interest to compare this approximate sequence with that obtained from the very detailed studies of Scandinavian peats. The following summary, taken chiefly from von Post, avoids most of the controversial points.

VEGETATION-CLIMATIC PERIODS.

1. Sub-Atlantic—Colder and moist.	Recent.	
2. Sub-Boreal—Drier: the warmest part of the post-glacial period	Bronze Age	*circa* 2000 to 1000 B.C.
	Stone Cists	Neolithic. English submerged forests are later than Littorina depression.
	Passage Graves	
	Dolmens	
3. Atlantic—Warm and moist	First Swedish Stage	Maximum extent of Littorina Sea.
	Transition — including Tardenoisien	
4. Boreal—warmer	Ending about 6000 B.C.	
5. Sub-Arctic	End of Palæolithic—beginning about 10,000 B.C. (De Geer).	

The warm Sub-boreal period in Scandinavia could scarcely fail to exert some influence in Scotland. Hence the estimate of the Upper Forest as being approximately of Bronze Age would receive some justification. The Neolithic Dolmen period apparently indicated at the base of the Pennine peat lies at the beginning of the Scandinavian Sub-boreal period, and we are apparently faced with the difficulty that the Scandinavian climate was becoming drier and more favourable to woodland vegetation while British climate was becoming colder (and moister ?). The evidence clearly suggests that either the Scandinavian and British culture periods were reached at different times or else that the climatic sequences were actually somewhat different. Much would depend, therefore, on the determination of cultural horizons in the Scottish peat. To these problems, one must in honesty add one more. The Pennine upland peats, as a whole, show few, if any, traces of Lewis's Upper Forest layer, although this is supposed to represent a time when the forest limit was very greatly raised both in Britain and Scandinavia. Further, in the Danish and Swedish lowland moors, this horizon is marked by a definite layer of "horizon peat"—the Sub-boreal surface.

A similar surface presents the only strikingly uniform horizon in the upper peat of the North Lancashire "mosses." It occurs about 3 to 4 feet below the surface, and below the peat is brown and partly decayed remains of Sphagnum and Eriophorum. Above this horizon, the peat is "white" and undecayed Sphagnum peat. Dr. Osvald, to whom I showed this, considered that it coincided with the Swedish Sub-boreal horizon. It certainly corresponds with a long period when the development of all the North Lancashire moors was arrested and when, according to Mr. Rankine, the surface was sufficiently firm to allow a corduroy road to be laid on it. Why is this horizon and that of the Scottish Upper Forest so conspicuously absent from the typical Pennine peats ? It must be confessed that these problems suggest that the climatic theories of peat succession are not nearly so firmly anchored in Great Britain as in Scandinavia. The further investigation of peats is likely to assume great importance and, in particular, the establishment of cultural horizons in the Scottish peats. The present indications clearly raise more problems than they solve.

New Measurement of the Velocity of Light.[1]

By Prof. A. A. MICHELSON, For. Mem. R.S.

THE velocity of light is one of the most fundamental of the constants of Nature, and this fact alone would justify the attempt to measure its value with the highest possible precision. But in addition to its scientific importance, it may prove to have a practical value if the result of such a measurement can be obtained with sufficient accuracy.

The mean of the various measurements thus far attempted is 186,330 miles per second, with an uncertainty of twenty or thirty miles. If this uncertainty could be reduced to one mile per second, the timing of light could be utilised to obtain distances between stations from 50 to 100 miles apart far more expeditiously and with an order of accuracy at least as great as that obtainable by the usual method of triangulation. Indeed, there are possibilities of utilising the velocity of light in cases where triangulation would be difficult or impossible.

An invitation tendered by Dr. G. E. Hale, then Director of the Mt. Wilson Observatory, and supported by Dr. J. C. Merriam, Director of the Carnegie Institution, made it possible to install the necessary apparatus on Mt. Wilson, with Mt. San Antonio, twenty-two miles away, as the distant station, during the summer of 1923; but smoke and haze from burning oil and from forest fires made it impossible even to test the feasibility of the method at so great a distance.

This feat was accomplished during the past summer with very promising results. The set-up of apparatus involved several important changes in the arrangement employed in previous investigations, the most important of which consisted in the substitution of an octagonal revolving mirror for the usual plane-parallel, together with the introduction of a system of reflectors which eliminated all direct and diffuse extraneous light. Finally, a simple method for returning the light from the distant station to the source was substituted for the plane mirror used for this purpose in previous work, and this equipment functioned so well that no readjustment was required during the entire two months of the work.

[1] Address delivered at the University of Pennsylvania on September 19, on the occasion of the observance of the centenary of the Franklin Institute. Reprinted from the Journal of the Institute for November 1924.

The advantage of the octagonal revolving mirror, in addition to the higher speed obtainable, lies in the possibility of receiving the return light on a succeeding face, thus eliminating the measurement of the angular deflexion of the returned beam; or rather, transferring this measurement to the construction of the octagon, the angles of which were tested and found to be equal, with an uncertainty of only one part in a million.

The determination of the velocity of light is thus reduced to the measurement of the distance between the stations, and of the speed of rotation of the mirror. The former operation was carried out by the U.S. Coast and Geodetic Survey, and the result obtained was 35,426·3 metres (about twenty-two miles), with an uncertainty of the order of only two parts in a million. The errors in the measurement of the speed of the revolving mirror were much greater, as no very effective means were employed to ensure its constancy. (This defect will be eliminated in the continuation of the work next summer.)

Notwithstanding the inconstancy of the speed of the mirror, the choice of the most favourable moment, when the speed was that corresponding to the frequency of a control tuning-fork, made the resulting uncertainty of the measurements of the order of one ten-thousandth part, which is about that of the mean of all the previous measurements. It is hoped that next year's work will furnish results four or five times more accurate.

The result of eight independent observations in the present preliminary work is, for the velocity of light *in vacuo*, 299,820 kilometres per second.

Following is a table of results of the more important investigations to date, with an estimate of the weight which should be assigned to each:

Investigator.	Method.	Distance.	Weight.	Velocity.
		km.		
Cornu	Toothed wheel	23	1	299,950
Perrotin	Toothed wheel	12	1	299,900
Michelson	Revolving mirror	0·6	2	299,895

Obituary.

DR. FRANZ DOFLEIN.

IT seems but a short time since we deplored the premature death of Prof. Minchin, and now protozoologists have lost another distinguished leader, Prof. Doflein of Breslau, who died at the age of fifty-one on August 26. It is by his excellent text-book, "Lehrbuch der Protozoenkunde," that Doflein is most widely known. The fourth edition, which appeared in 1916, has been out of print for some years, and he had been working for the last three or more years on a fifth edition, although often interrupted by illness, aggravated by depression caused by the War. However, it is some satisfaction to learn that this new edition may be expected soon to appear, as it is being prepared for the press by Prof. Reichenow, of the Institute of Tropical Medicine in Hamburg.

Many in Great Britain will remember Prof. Doflein's charming personality and his readiness to help any one interested in his subject. He attended the Dundee Meeting of the British Association in 1912 and worked much at the Zoological Stations of Naples and Rovigno as well as in the Musée Océanographique at Monaco.

Franz Doflein was born in Paris in April 1873, his mother being of English origin and his father a German merchant. At seven years of age, on the death of his father, he was taken to Germany to be educated. In 1896 he went to the University of Munich to study medicine, but, coming under the influence of Prof.

Hertwig, he decided to devote himself to zoology. After graduating, several university posts were held by him in Munich until 1912, when he was appointed Weissman's successor as professor of zoology at Freiburg. Here he taught for six years, finally moving to Breslau in the autumn of 1918 to become Director of the Zoological Institute in succession to Kükenthal.

A many-sided naturalist, Doflein published work on crabs, ants and Bdellostoma as well as his numerous important papers on the protozoa. The first edition of his text-book appeared in 1901 under the title "Die Protozoen als Parasiten und Krankheitserreger." The second edition five years later was the first to be known as the "Lehrbuch der Protozoenkunde," and it included descriptions of free-living as well as parasitic protozoa. In collaboration with his friend Richard Hesse, Doflein recorded their observations on living animals in a popular book entitled "Tierbau und Tierleben," which appealed to a large circle of readers. In addition to this, he wrote popular books on three scientific expeditions undertaken by him—to the West Indies, Japan and Macedonia. The last, on his Macedonian travels, published in 1921, is illustrated with his own water-colour sketches.

In the early part of 1923, owing to continued ill-health, Doflein resigned his appointment in Breslau, and he died of pneumonia on August 26, 1924. Thus was tragically cut short a life of great achievement, for not only did he contribute much to biology himself but he also attracted many students to his laboratories, where they were allowed to follow their own lines of research, although always sure of his help in difficulty. His liberality and broad-mindedness were indeed part of that artistic temperament which delighted all with whom he came in contact.

THE *Chemiker Zeitung* of November 4 records the death, on October 25, at the age of seventy-two, of Dr. Carl Huggenberg, one of the pioneers among German public analysts. Huggenberg's name is associated with the well-known Analytical Institute founded by him at Chemnitz, where most of his public work was carried out. Born of Swiss parentage at Winterthur, he studied first at Zurich and later at Würzburg, where he became assistant to J. Wislicenus, and graduated in 1876. During the following three years he held an official appointment as analyst of foodstuffs in the Canton of Zurich. This special branch of applied chemistry was still in its infancy at that time, but in all the German towns, associations were being formed with the object of fighting against the adulteration of food. In 1882, the association which had been founded five years previously at Chemnitz by L. Friedrich, offered Huggenberg the direction of its laboratory. Here he found full scope for the development of his natural powers. His analytical skill, his comprehensive knowledge of chemistry, and his practical insight into the needs of industry and commerce were invaluable assets to him, and his opinion on technical matters was soon widely sought. His interest in technology led him to make numerous valuable investigations in oils, fats, and soaps, and he made numerous contributions to scientific literature on the refractometry of soap-fats, the recovery of waste fat, and on soap analysis. Until 1902 he also held the post of food controller at Chemnitz. In 1910 he retired to Zurich.

Current Topics and Events

THE Fishery Board of Scotland recently issued a notice to fishermen and others directing attention to the protection afforded to the grey seal under the Grey Seals Protection Act of 1914, which lays open to a penalty of 5*l.* any person taking, killing, or wounding grey seals during a close season, October 1-December 15. The publication of the notice has led to correspondence in the Scottish newspapers, the protection of this seal being condemned on the ground that it is increasing in numbers and is responsible for the destruction of some of the Hebridean cod fisheries. The weight of the evidence, however, seems to indicate that the grey seal is very rapidly decreasing in numbers on the west coast, and that the constant slaughter of the young in certain breeding haunts, their pelts being sent in considerable numbers to furriers in Glasgow, threatens the existence of the species in these waters. As regards the destruction of fisheries, the assertion is made that dog-fish and not cod form the diet of the seal, and that the destruction of seals and consequent increase of dog-fishes are responsible for the deficiency of cod. The point is an important one, which is left undecided by the assertions of the correspondents. It might readily be settled by the examination, by an expert in fragmentary fish remains, of a few series of stomach contents taken at appropriate seasons.

THE Field Museum of Natural History, Chicago, has arranged a series of twelve free programmes of moving pictures, with occasional lectures, illustrating natural history subjects, for children on Saturday mornings from October to December. The subjects include "Wild Animals I have known," by Mr. Ernest Thompson Seton, Capt. Kleinschmidt's "Polar Adventure," Theodore Roosevelt's "Visit to a Bird Reservation," and a number of films illustrating particular facts and aspects of zoology, botany, and geology. At each entertainment a little printed "museum story" is given to each child. This story gives, in simple language, some brief facts about the men, animals, and plants seen in the pictures, and directs the child to the case or cases in the Museum in which they are exhibited. By directing attention to the permanent exhibits in this way, opportunity is afforded to the child to crystallise the general impressions and information gathered from the films, and the real educational value of the scheme is thereby enormously enhanced. It surely is more than a series of entertainments, as the programmes are described on the syllabus. The experiment will be watched with great interest not only by those who believe in the vast potentialities of museums in education, but also by those who are convinced of the possibilities of the cinematograph as an aid in the same field.

THE proposal made by James Watt in 1783, that international units of weights and measures should be adopted, was the direct origin of the metric system. The strongest argument in favour of this system, as was pointed out by Sir Richard Gregory in his presidential address to the Decimal Association on November 26, is its international character. Scarcely a year passes without the addition of one or more countries to the list of those which have adopted metric weights and measures as their sole standards, while not a single country has introduced British measures to supersede its own. One of the latest additions to this Metric League of Nations is Japan, where metric weights and measures became official on July 1 of this year. The change was made as the result of the report of a Commission of Inquiry, which gave careful consideration to the advantages, from the points of view of industry and commerce, of the British, metric and other systems. Great Britain and the United States are responsible for so large a proportion of the world's trade that it would seem that this of itself would have led to the adoption of their weights and measures by other countries; yet whenever a country has appointed a Commission to inquire into the desirability of a change of units, it has always reported in favour of the metric system and never of the British. When Germany introduced the metric system, it seemed to be against immediate manufacturing interests on account of the overpowering superiority of British trade at the time. What decided the question then, as it should now in Britain, is that the metric system is an international system. At the annual meeting of the Decimal Association, Mr. A. J. Stubbs was elected vice-chairman of the executive committee, and the following were elected new vice-presidents: Sir Hedley le Bas, Mr. Llewellyn Atkinson, Mr. Harold Cox, and Mr. Gordon Selfridge.

AN interesting and little known chapter was added to the history of mechanical transport by Col. R. E. Crompton in his paper on "The Motor Car: its Birth, its Present, and its Future," read to the Royal Society of Arts on November 12. Col. Crompton's aim was avowedly "to vindicate the memory of that great Scotsman" Robert William Thomson, who was born on June 29, 1822, and died on March 8, 1873. A prolific inventor, Thomson as a young man came in contact with Faraday, Cubitt, and Stephenson, and then in 1844 set up in business for himself. The following year he took out his patent for the pneumatic tyre, an invention made possible by the rubber pioneers Macintosh, Goodyear, and Hancock. Thomson's tyre, however, was used but little, and Dunlop's re-invention of it forty years later was an independent one. By 1862 Thomson had a consulting practice in Edinburgh, and in 1867 he built a three-wheeled steam road locomotive for colliery work in Labuan, the wheels having heavy ring rubber tyres. Col. Crompton, then a young lieutenant in the Rifle Brigade in India, learning of this, got into correspondence with Thomson and was able to persuade the Government authorities to try steam locomotives on the Indian roads. In 1870 Col. Crompton came to England, spent some time at the home of Thomson, who by then was an invalid confined to his sofa, and supervised the building of two road engines, the "Chenab" and "Ravee." With a permit to test the engines on the roads at speeds greater than those allowed by the notorious Red Flag Act, the "Ravee" in September 1871 went from Ipswich to Edinburgh and back, hauling a large omnibus, and near Doncaster attained a speed of 25 miles per hour. In India the engines were in the first place used for Post Office work and then for military transport. It was the experience thus gained which led to Lord Roberts' advocacy of mechanical transport in South Africa in 1900. Thomson's achievements as one of the great pioneers of modern road haulage have often been acknowledged, and two years ago the Royal Automobile Club placed a tablet to his memory on the site of the house in which he was born in Stonehaven, Kincardineshire.

THE Engineering Department of the University of Cambridge has attained a leading and distinguished position among the engineering schools of Great Britain, and the illustrated descriptions of its new laboratories published in the *Engineer* for October 24 are of great interest. There are indications that the number of engineering students at Cambridge will become stabilised at about 500, which is approximately the present figure. The new laboratories stand on the Scroope House site in Trumpington Street, which occupies an area of about 4 acres. The buildings mostly consist of one-storied north-lighted structures of the factory type. The laboratories were completed and equipped in 1922 at an approximate cost of 100,000*l*., but no money was available for the construction of the projected two-storied lecture room block. In consequence, lecture rooms and laboratories are separated by a considerable distance, and the authorities hope that this inconvenience may be remedied soon by some generous benefactor; a further sum of 60,000*l*. is required. Provision is made in the laboratories for experimental work on heat engines, including engines and boilers, materials, structures, hydraulics, electrical engineering, including wireless telegraphy, and metallurgy. The equipment of all these laboratories is on a generous scale, and a large number of the machines has been presented by engineering firms. Whilst the Department also possesses workshops, we note with approval that students are encouraged to spend some of their vacations in real engineering workshops, and are advised, if possible, to serve in an engineering workshop for about six months prior to starting the course at the University.

NOMINATIONS for the award of the Elliot Medal of the National Academy of Sciences, Washington, for the year 1924 should be addressed to the secretary of the Academy. The terms of the award in the Daniel Giraud Elliot deed of gift are as follows: "One such medal and diploma shall be given in each year and they, with any unexpended balance of income for the year, shall be awarded . . . to the author of each paper, essay, or other work upon some

branch of zoology or palæontology published during the year as in the opinion of the . . . judges in that regard shall be the most meritorious and worthy of honor. The medal and diploma and surplus income shall not, however, for more than two years successively, be awarded for treatises upon any one branch of either of the sciences above mentioned. . . . The medal and diploma and surplus income may be conferred upon naturalists of any country and . . . no person acting as judge shall be deemed on that account ineligible to receive this annual gift . . . if, in the opinion of his associates, he shall . . . be entitled to receive them." The treasurer of the Academy reports that the Elliot Fund has increased since the original donation of 8000 dollars. The best idea of the kind of work for which this award was designed may be gathered from a résumé of previous awards: 1917, to Frank M. Chapman for his "Distribution of Bird Life in Colombia"; 1918, to William Beebe for his "Monograph of the Pheasants," volume i.; 1919, to Robert Ridgway for his "Birds of North and Middle America," Part VIII.; 1920, to Othenio Abel for his "Methoden der paläobiologischen Forschung"; 1921, to Bashford Dean for his "A Bibliography of Fishes," volume i.; 1922, to William Morton Wheeler for his "Ants of the American Museum Congo Expedition"; 1923, to Ferdinand Canu for his "North American Later Tertiary and Quaternary Bryozoa." Unlike other awards, the Elliot Medal is always for a special piece of research in zoology or palæontology completed and published in the year for which the award is made. The Committee particularly desires that nominations shall be received for foreign as well as for American work during the year 1924. Recommendations should be accompanied by a printed copy of the research submitted for consideration.

HEATHFIELD HALL, Birmingham, where James Watt lived from 1768 up to the time of his death, and where many of his experiments were carried out, having been sold, the former owner, Major Gibson Watt, has presented to the Science Museum, South Kensington, the contents of the attic workshop in which Watt worked. After Watt's death the room remained closed for some forty years, and all the contents still remain practically as he left them. A room, which will reproduce as closely as possible the attic at Heathfield Hall, is about to be constructed in the Science Museum on the ground floor of the new Museum buildings not far from the two Boulton and Watt engines which are preserved there. In this room the furniture, tools, two or three machines which Watt used, as well as many trial pieces, etc., will be placed on view.

ACCORDING to messages which have appeared in the daily papers, photographs were successfully transmitted by radio across the Atlantic in some tests carried out on Sunday, November 30. The transmitting apparatus was installed at Radio House, London, and the radio signals were picked up at Long Island and transmitted to New York by land lines. Brief descriptions of the apparatus have been issued, from which it appears that a photographic film is attached to a rotating glass cylinder and the actual emission of radio signals is regulated by a photo-electric cell under the influence of the light which traverses the photographic film. After each revolution of the drum carrying the film, the latter is automatically moved by a fixed amount; in the recent experiments the shift was $\frac{1}{128}$ in., but it is stated that $\frac{1}{64}$ in. would be sufficient. It takes about twenty minutes to transmit a half-plate film. The invention has been developed by Mr. D. H. Ranger, of the Radio Corporation of America. According to the New York correspondent of the *Times*, the receiving apparatus executes on paper a pen-and-ink reproduction resembling an engraving, and it is stated that the photographs transmitted in the test were easily recognisable. The general principles of the transmission of a film record by means of the action of light on a selenium cell were described by Prof. A. O. Rankine in articles in NATURE of February 5, 1920, p. 604; October 27, 1921, p. 276; and June 2, 1923, p. 744.

PROF. RISLER, working in the Laboratoire Physiologique des Sensations at the Sorbonne, has produced tubes filled with air or other gas at low pressure, excited by high-frequency current, with phosphorescent and fluorescent materials and pigments, either applied to the tubes or incorporated in the glass. The result is an emission of light, with little or no long wave-length red or infra-red radiation and no green, to which the name "cold light" has been applied. It is claimed that a large tube gives 12,000 candle power with an input of 2·5 kilowatts. A special arrangement of the electrodes maintains the pressure automatically at the optimum point, so that some of the tubes have worked for 9000 to 10,000 hours without any noticeable diminution in their illuminating power. A large quantity of ultra-violet radiation is given off, and the tubes have proved valuable for therapeutic purposes. When the current is switched off, the tubes continue to glow with phosphorescent light, the colour of which is different from that emitted previously, and the tubes appear suitable for use in advertising. Particulars of the tubes can be obtained from Mr. D. L. Daponte, 147 Cannon Street, E.C.4.

PROF. A. W. BICKERTON has been elected an honorary member of the New Zealand Astronomical Society in recognition of his work on cosmic evolution.

PROFS. THEODORE LYMAN, of Harvard University, and Gilbert N. Lewis, of the University of California, have been elected honorary members of the Royal Institution, London.

MR. E. LEONARD GILL, assistant in the Natural History Department of the Royal Scottish Museum and formerly Curator of the Hancock Museum, Newcastle-upon-Tyne, has been appointed Director of the South African Museum in succession to the late Dr. Louis Albert Péringuey. The assistantship in the Royal Scottish Museum therefore becomes vacant and applications are invited.

AT the opening of the hundred and fifty-fourth session of the Royal Physical Society of Edinburgh, the following new office-bearers were elected: *President*, Dr. James Ritchie; *Vice-Presidents*, Dr. Marion Newbigin and Prof. J. Arthur Thomson; *Secretary*, Dr. H. M. Vickers; *Assistant Secretary*, Prof. J. Russell Greig; *Librarian*, Mr. J. Kirke Nash; and *Councillors*, Prof. D'Arcy W. Thompson, Principal O. Charnock Bradley, Prof. J. H. Ashworth, Prof. J. Graham Kerr, Dr. J. R. Henderson, and Mr. Hugh Miller.

THE Rivers Memorial Medal of the Royal Anthropological Institute for the year 1924 has been awarded to Dr. A. C. Haddon. This is the first occasion on which the medal has been awarded. In future one or more medals will be given annually in recognition of meritorious anthropological work in the field, in memory of the late Dr. W. H. R. Rivers, who was president of the Royal Anthropological Institute at the time of his death. Apart from Dr. Haddon's unquestioned claims as a field worker in ethnology, it is peculiarly appropriate that he should be the first recipient of this honour in view of the close association of Dr. Rivers with him when the latter first took up his investigations among primitive peoples.

A GROUP of papers on "Base Exchange in Soils" will be presented for discussion at a meeting of the Faraday Society to be held in the rooms of the Chemical Society, Burlington House, London, on Tuesday, December 9, at 4.30-7.30 P.M. The chair will be taken by Sir Daniel Hall, scientific adviser to the Ministry of Agriculture, and an introductory address will be given by Dr. D. J. Hissink, of Groningen. Further particulars may be obtained from the Secretary of the Faraday Society, 90 Great Russell Street, London, W.C.1. Papers will be presented by Prof. N. M. Comber (University of Leeds), Messrs. H. J. Page and W. Williams (Rothamsted Experimental Station), Prof. G. W. Robinson and Mr. Rice Williams (University College, Bangor), Mr. S. J. Saint (University of Leeds), and Mr. E. A. Fisher (Research Association of British Flour-millers).

AN extra meeting of the Institution of Civil Engineers will be held on Thursday, December 11, at 6 P.M., in conjunction with the Institutions of Mechanical Engineers, Electrical Engineers, and Naval Architects, the Institute of Marine Engineers, the North-East Coast Institution of Engineers and Shipbuilders, the Institution of Engineers and Shipbuilders in Scotland, the Institute of Chemistry of Great Britain and Ireland, the Institution of Gas Engineers, the British Electrical and Allied Manufacturers' Association, and the British Engineers' Association. These bodies are co-operating in the work of the special committee on tabulating the results of heat-engine and boiler trials, and the chairman of the committee, Capt. H. Riall Sankey, will submit for discussion: "Standards of Comparison in connection with the Thermal Efficiency of Steam Engines."

THE before-Easter lecture arrangements at the Royal Institution have just been issued. The general courses will begin on Tuesday afternoon, Jan. 13, at 5.15, when Prof. A. Fowler will commence a course of two lectures on the analysis of spectra; on succeeding Tuesdays there will be two lectures by Dr. H. R. Hall on the prehistoric Greek and ancient Egyptian civilisations, four by Prof. Barcroft on the colour of the animal creation, two by Prof. E. N. da C. Andrade on the evolution of the scientific instrument, and two by Prof. A. S. Eddington on the internal constitution of the stars. Thursday afternoons at the same hour beginning on Jan. 15, Mr. J. S. Huxley will give two lectures on the courtship of animals and its biological bearings; Sir William Bragg, four on the properties and structure of quartz; Sir A. Smith Woodward, two on dinosaurs; Dr. Leonard Hill, two on the biological action of light; and Mr. T. Thorne Baker, two on chemical and physical effects of light. The Saturday lectures will include four by Sir Ernest Rutherford on counting atoms, and two by Prof. J. H. Ashworth on a zoological topic. The Friday evening meetings begin on January 16 with a discourse by Sir William Bragg on the investigation of the properties of thin films by means of X-rays. Succeeding discourses will probably be given by Dr. A. W. Crossley, Profs. J. W. Gregory, R. W. Chambers, T. H. Pear, Gilbert Murray and J. W. McBain, Principal Irvine, Mr. W. B. Hardy, Sir Ernest Rutherford, Sir Daniel Hall and other gentlemen.

THE autumn issue of *Bird Notes and News*, the journal of the Royal Society for the Protection of Birds, is a double Dominions number and contains interesting papers written by prominent bird-protectionists relating to the work of bird protection in Australia, New Zealand, Canada, British Columbia, Newfoundland, and South Africa. A comprehensive report on the bird-life of the sanctuaries in the Royal Parks in London, by a member of the sanctuaries committee, forms an enlightening and encouraging leading article; and the effort the Society is making to combat the oil menace to sea-birds is further evidenced.

THE National Research Council of Japan has initiated an active programme of scientific publication, in several series of "Japanese Journals" under the separate headings of chemistry, physics, geology and geography, botany, zoology, medical sciences, engineering, mathematics, and astronomy and geophysics. The first two of these journals each appear in ten numbers annually, the third appears quarterly, while the remainder are occasional publications. The second part of volume ii. of the *Japanese Journal of Astronomy and Geophysics* has just been issued, and contains six memoirs, occupying about sixty octavo pages. The papers cover a wide range of interests—precise levelling, theory of monsoon rainfalls, gravitational fields, thermal expansion of rocks, and tidal undulations — and in some cases originate from

research institutes, independent or connected with universities or colleges. They indicate a highly satisfactory state of activity and interest in geophysical research in Japan. All the papers are in English.

INSTRUCTIONS and information relative to wireless reports of weather on the coast of Brazil have been issued by the Brazilian Meteorological Service. The Director, Señor Sampaio Ferraz, who is responsible for the issue of the information, is thoroughly conversant with the meteorological requirements. With the view of assisting navigation, twelve transmitting stations have been established on the coast and send observations six times a day, every four hours, of the force and direction of wind and the state of weather and sea. In case of storms and dense fogs, these frequent messages should prove useful to approaching vessels. The reports are expressed in Portuguese, but very simply. The messages from the transmitting stations are sent on 600 m. waves spark. Rio's special messages, sent out twice daily, include detailed forecasts for the south coast of the State of Rio de Janeiro and general forecasts for the rest of the southern Brazilian coast and up to Buenos Aires; the first part, organised by the international code, gives barometric pressure, force and direction of wind, state of weather and air temperature. The instructions contain specifications of the international codes, and every facility is afforded for commanders navigating these seas to draw for themselves weather charts which will give them full information of the conditions of the weather over the whole neighbourhood.

THE British Dyestuffs Corporation, Ltd., Manchester, has issued a booklet entitled "Medicinal Products: A booklet issued to the Medical Profession," which gives an account of the various dyestuffs which have found a therapeutic application, and also of some chemicals that are used as reagents in clinical tests. The formula is given in each case, together with a considerable number of references to papers in which the use of the products is described. The main section is devoted to a consideration of the flavine antiseptics, and is followed by one on the di- and tri-phenyl-methane series: namely, auramine, crystal violet and brilliant and malachite green. Among other dyes considered may be mentioned trypan blue, Biebrich scarlet, gentian violet, methylene blue and picric acid with their therapeutic uses, and indigo-carmine which has been used for testing the function of the kidneys. In the last section a brief account is given, amongst other compounds, of benzidine, dimethylp. aminobenzaldehyde and phenylhydrazine hydrochloride and their use in clinical tests. The booklet should be useful to all those who desire information on the constitution and reactions of any substances in the above groups which they may happen to be using.

Our Astronomical Column.

THE GREAT FIREBALL OF NOVEMBER 11.—Mr. W. F. Denning writes that the fireball of November 11, 5 h. 40 m. G.M.T., was observed by a great number of persons in Ireland and extreme north of England. Sixty-nine accounts of it have been received, and though the observers were taken by surprise and most of them inexperienced in recording meteors, their results are in very fair agreement. At most of the stations the moon, which was nearly full, was near the beginning point of the meteor and furnished a useful guide to position.

The fireball had an exceptionally lengthy flight, and a very long duration, the average time being 33 seconds, when proper allowance is made. The whole of the luminous course appears to have extended over 510 miles, and the velocity was 16 miles per second. It passed from over the North Sea, 80 miles east of Hartlepool, across the extreme north of England and south of Scotland and onwards over the Atlantic Ocean, to Long. $11\frac{3}{4}^\circ$ west, Lat. $56\frac{1}{2}^\circ$ north. The average height was about 53 miles. The radiant point was as nearly as possible at $31^\circ - 6^\circ$ near Mira Ceti. As the fireball sailed along in its nearly horizontal course it showed some curious variations of colour; in the head blue and yellow predominated, while flakes of red were distributed along the tail. The effect produced was that of a brilliantly coloured snake-like object wriggling its course through our resisting atmosphere. Some of the observers compared the oval head to the size of a football; others thought it equal to the moon's diameter or to half the latter value. Adopting the smaller estimate, the nucleus would be half a mile in diameter, but this included the outlying flames and luminous off-come resulting from its combustion. The real size of the solid nucleus may not have been more that two or three feet.

OBSERVATIONS OF MARS.—*L'Astronomie* for October contains a number of drawings of the planet, made in September at Juvisy and Meudon. The large dusky areas are represented in much the same manner as by the American draughtsmen, but the canals as a rule are broader and more diffused; some of them appear on almost all the drawings, so that there is practically a consensus as to the existence of the markings, the difference only extending to their exact aspect. Thus, M. Quénisset on September 19 drew the Ganges as a very broad dark streak, fully 300 miles wide, with straight parallel edges.

M. E. M. Antoniadi has again observed the planet with the great Meudon refractor and contributes some very beautiful drawings. As is well known, he rejects the geometrical aspect of the canals and draws them as broad irregular shadings. He reproduces for comparison his drawings of Pandoræ Fretum made in 1909 and 1911, which show a marked change of intensity of this region from one year to another. He lays stress on the planet being a living world, and is inclined to return to the old notion that those dusky areas that do not show a seasonal change of tint are veritable seas.

M. Quénisset also observed Uranus with the Meudon refractor, and distinctly saw two equatorial belts and dusky regions at the poles. The aspect was quite like that of Jupiter except that the belts were nearly vertical.

Research Items.

MEDIEVAL METALLURGY.—An interesting article on medieval metallurgy, by M. L. Becker, appears in the Memoirs and Proceedings of the Manchester Literary and Philosophical Society (1923–1924, No. 4). No important metallurgical information of early times can be obtained from works prior to those of Dioscorides (first century A.D.), who describes brass and the recovery of zinc oxide. Pliny at the same period describes the smelting of metals, but he does not appear to have had practical experience in this direction. The really important literature dates from the eleventh century onwards, and includes the works of Theophilus and Agricola. The latter's contributions to metallurgical science, embodied in his book "De Re Metallica," are considered in detail, many illustrations being reproduced.

PAUPERISM IN THE UNITED STATES.—Prof. Raymond Pearl contributes to *Science* of October 31 an interesting note on the racial composition of paupers in public almshouses in the United States. Between 1910 and 1923 the proportion of foreign-born white paupers decreased from 42·6 per cent. to 32·6 per cent. The countries of origin which showed the greatest proportional excess of the paupers, having regard to their percentage shares in the whole population, were Ireland, Germany, and England, in that order. "With a few trifling exceptions," writes Prof. Pearl, "all the countries from which the present law *encourages* immigration contributed to almshouse pauperism in 1923 in *excess* of their representation in the population in 1920. On the other hand, again with a few trifling exceptions, those countries from which the present immigration law was especially framed to *discourage* immigration appear in the lower part of the diagram, because they contribute a *smaller* proportion to almshouse pauperism in 1923 than their representation in the general population in 1920."

ASYMMETRY OF THE AXIS IN THE PRIMATES.—In the course of a comparative study of the mammalian axis, Dr. Delattre has found that the axis of primates, and particularly of the anthropoids, is asymmetrical in a large proportion of cases. In the current issue of the Bulletin of the Société d'Anthropologie de Paris (Sér. VII. t. iv. fasc. 4-5-6), he describes the deformation and endeavours to account for its occurrence. Beyond the primates it does not occur among the mammalia except in certain carnivora and ungulates. There are several theories which are held to account for its occurrence in man, such as unequal action of the spinal muscles on one side. Any inequality in the lower limbs involves a compensating curvature in the vertebral column, as will also any deformity or defect tending to unilateral action. Although an inequality of the lower limbs is of sufficiently common occurrence among the primates, the asymmetry of the axis is rather to be attributed to a special attitude which is an accompaniment of the arboreal life. One of the upper limbs being employed constantly in prehension is habitually raised and held in a more forward position than the other. The torsion of the trunk and the constant thrust forward of the head causes an unequal action of the muscles which produces a deformation of the cervical vertebræ.

HISTORY OF CIVILISATION.—An Occasional Paper (No. 6) lately issued by the Royal Anthropological Institute is of the first importance for students of races and history. The early pottery of the near East has been summed up by Mr. H. Frankfort of Amsterdam, in a thesis for his M.A. degree in the University of London. He deals with Mesopotamia, Syria, and Egypt and their earliest interrelations in 142 well-illustrated pages. During the last third of a century our view of the past has been immensely enlarged; the four civilisations known before the present one have been extended now to eight. The great mass of new facts remained mostly in their original monographs, in which they had been partly explained. The summing up of them as a whole, in full view of all the material, was a work much needed, and Mr. Frankfort has done it with great diligence, searching out unpublished specimens, and with remarkable judgment and sanity. He carefully distinguishes the ideas often vaguely expressed, of racial and artistic terms, and seeks to secure every precision and definition available. The discussion of Mesopotamian material leads to the conclusion that the earliest Susian civilisation was crushed by drought, which drove the people down to the rivers. They were neither Semite nor Sumerian, and the Sumerians came up later from the Persian Gulf. Their possible Indian connexion has been rendered much more likely by the recent discovery of quasi-Sumerian engraving and signs in India. As to Egypt, it is well to find that the explanations given at the time of new discoveries during the last quarter of a century hold good in almost every point. The scantiness of the Asiatic discoveries is scandalous, now that the regions are more accessible, and sites are liable to be destroyed by commercial business. The opportunity will not keep, and both men and money are wanted speedily for Eastern research in civilisations.

FUNGI AND EPILEPTIFORM CONVULSIONS.—In the Transactions of the Mycological Society, 10, p. 121, Prof. J. Russell Greig describes the association of fungus spores with epileptiform convulsions in dogs. In three cases showing the symptoms (two of which died), the fæces and intestines were found to contain spores of *Tilletia Tritici*, the stinking smut of wheat. These were present in very large quantity and were conceivably derived from straw used for bedding. In the cases examined, no macroscopic lesion was visible in the body, but in one case in which the cranium was also investigated, an acute cerebral meningitis was observed, associated with numbers of spores. The fungus spores are often present as isolated specimens in the fæces of normal dogs. There appears to be evidence that they can be absorbed by the intestines, though how this is accomplished in the case of an inert body of about 18μ in diameter, remains to be determined.

TRANSPIRATION OF XEROPHYTIC PLANTS.—It is now generally recognised that the thick cuticle, sunken stomata and other structures characteristic of plants growing in dry places do not necessarily produce any noteworthy modification in the rate of transpiration. This point has now been examined for a number of typical Australian xerophytes by Mr. H. W. Wilson (Proc. Roy. Soc. of Victoria, 36, N.S., pp. 175-237), who was unable to find that these plants had any special powers of accommodation when subjected to rapid increases in temperature or to hot winds. The so-called xerophytes are, in fact, provided with a high average number of stomata, and they respond very rapidly to changes in the evaporating power of the air. The phyllodes of the Acacias and the leaves of the Eucalypts in particular, are regarded by Mr. Wilson as almost perfect transpiring organs. One of the curious features of the results to which no reference is made, is that the average transpiration rate per

million stomata bears no apparent relation in different species to the depth to which the stomata are sunk or to the degree to which they are protected by hairs or other excrescences.

BROWN BAST DISEASE OF RUBBER TREES.—In the *Malayan Agricultural Journal*, Vol. 12, September and October 1924, pp. 290-343, Messrs. A. Sharples and J. Lambourne record a very large number of further field experiments upon this subject in continuation of the experiments referred to in NATURE of February 17, 1923, p. 234. These experiments leave them still more firmly convinced of the physiological origin of this disease, as opposed to the bacterial origin suggested by P. E. Keuchenius. On the other hand, they are unable to agree with Prof. J. B. Farmer and Mr. A. S. Horne that phloem necrosis is a significant primary feature of the disease, as they find lignification of the sieve tubes a common feature of the phloem in healthy trees. They conclude that over-extraction of latex is the most important factor in initiating the disease, and suggest that this may cause an excessive loss of water to the plant at times or seasons when this loss of sap seriously affects the water balance in the tissues. These authors seem somewhat pessimistic as to the possibility of developing successfully high yielding plantations by methods of vegetative propagation (bud-grafting). It is difficult to select the tree in which high yield of latex is an intrinsic quality and not the result of favoured position and climate, and difficult to know whether such high yield is associated with resistance to brown bast disease. The authors argue that such high-yielding trees will have leaves more liable to fungus attacks, though their reasons for such a pessimistic conclusion do not read very convincingly.

FOG AT THE SCILLY ISLES.—Fog frequency at Scilly during summer months in relation to weather types indicated by barometric pressure is discussed by Mr. E. G. Bilham in Professional Notes, vol. 3, No. 37, issued by the Meteorological Office, Air Ministry. The investigation is somewhat tentative, more complete work being in hand, but as fog at the entrance to the Channel is of considerable importance to seamen, the facts at present to hand are published. In the summer months "fog" as distinct from "mist" is reported at Scilly on one day in seven, and including "mist," the frequency is at least twice as great. Only days with fog are included in the present inquiry. The period dealt with is the fourteen years 1905 to 1918, which gives 1288 days, and as there were 192 fogs the chances against fog are nearly 6 to 1. Of the total fogs, 61 occurred in June, 60 in July, and 71 in August. In individual months the fogs varied from none in August 1905 to 12 in June 1915. In individual years the number of fogs for the three summer months combined varied from 8 in 1909 to 24 in 1914. The numbers are given for each of several types of pressure distribution. Illustrations are given of the several foggy types and of the clear weather types. With a large area of high barometer over Scandinavia and several smaller ones to the south-west, the chances are only 1·4 to 1 against fog at Scilly. No fog was recorded during the summer months in 14 years at Scilly with a "V" shaped depression over the east of England or with a high barometer over Scandinavia and low over Mediterranean. With high barometer to the north-west of the British Isles and low over the north of France, the chances against fog are 24 to 1.

THE RECOIL OF THE ELECTRONS WHICH SCATTER γ-RAYS.—Mr. D. Skobelzyn describes, in the *Zeitschrift für Physik* of October 14, an investigation of the γ-rays of radium, in air, by the Wilson cloud method. A magnetic field was employed, perpendicular to the path of the γ-rays. This caused the resulting β-rays to move in spiral and often in circular paths. It prevented β-rays produced on the walls from penetrating into the space surrounding the γ-ray beam, and made it easy to investigate the β-rays from the gaseous atoms. Although the energy given by a hard γ-ray to an electron is in some cases nearly equal to $h\nu$, in many others it is only a small fraction of this quantity. It is also found that the initial velocity of the electrons has always a forward component, and that the energy depends on the angle θ between the direction of the initial velocity and that of the γ-ray, being on the average smaller as θ increases. These results are in accord with the hypothesis of Compton that, in the case of the lighter atoms, the secondary β-rays are recoil electrons, and contrary to that of Wilson and Bauer, according to which the scattering of the γ-ray takes place as a spherical wave, and that the whole elementary impulse of the radiation $h\nu/c$ is given up to the electron.

HEAT INSULATORS.—Special Report No. 5 by the Engineering Committee of the Food Investigation Board (First Report on Heat Insulators, Experiments. Second Edition. London: H.M. Stationery Office. 2*s*. net), deals with the first series of measurements made by Dr. E. Griffiths at the National Physical Laboratory of the heat conductivities of some of the heat insulators used in the construction of refrigerating stores. Dr. Griffiths finds that the heat conductivities of good dry cork, slagwool, charcoal and wood fibres at ordinary cold stores temperatures are all about 0·00011 C.G.S. units. Different brands of the same material differ to some extent in conductivity, and some of the materials at present used for heat insulation are liable to deterioration in situations where they may be subjected to heat or vibrations. In one case the conductivity had increased 40 per cent. Of the 17 materials tested, one—expanded rubber—appears to be little known as a heat insulator although its heat conductivity is about the same as that of cork.

COAL DUST EXPLOSIONS.—Prof. H. B. Dixon's presidential address before the Manchester Literary and Philosophical Society, which dealt with coal-dust explosions, is printed in the Memoirs and Proceedings of the Society for 1923–1924. A general account of the work carried out at Eskmeals is given. A coal-dust cloud can be ignited and can propagate a flame, but this cloud must pre-exist before the flame reaches it. The effect of the presence of inert dust varies; if the explosion wave is set up in pure coal dust it will continue to travel for some distance when it meets a dust containing as much as 75 per cent. of inert dust. A mixture of equal parts of coal dust and inert dust may propagate an explosion, provided there is an intense explosion flame to start it; such a mixture may be exploded by the discharge of 24 oz. of blasting powder.

DIAZONIUM TETRACHLOROIODIDES AND PLUMBICHLORIDES.—These compounds are described by F. D. Chattaway, F. L. Garton, and G. D. Parkes in the October issue of the Journal of the Chemical Society. The tetrachloroiodides are among the most stable of diazonium derivatives and they separate as yellow crystals when cooled solutions of diazonium chlorides are poured into cooled concentrated hydrochloric acid solutions of iodine trichloride. They are decomposed by hydriodic acid to the corresponding iodobenzene derivative; on heating with alcohol the diazo-group is mainly replaced by chlorine. Diazonium plumbi-

chlorides are prepared as above with the substitution of lead tetrachloride for iodine trichloride. They react with hydriodic acid and alcohol in the same way as the tetrachloroiodides. They all decompose explosively at a definite temperature; the tetrachloroiodides melt sharply, although always with decomposition.

EXPLODING AMMONIA WITH ELECTROLYTIC GAS.—The products obtained by exploding ammonia with varying amounts of oxygen and of electrolytic gas have recently been examined by J. R. Partington and A. J. Prince, the results being published in the Journal of the Chemical Society for October. Mixtures of electrolytic gas with ammonia are explosive when the former constituent is in slight excess; 79 per cent. of the ammonia is decomposed under these conditions. Complete decomposition occurs when the proportion of electrolytic gas just exceeds 75 per cent. When more than 1·6 parts of ammonia are exploded with 1 part of oxygen, the latter unites preferentially with the hydrogen, leaving a residue of nitrogen and excess hydrogen. When less than 1·6 parts are used, oxides of nitrogen are formed; the maximum oxidation of nitrogen is 16 per cent. and occurs when the ratio of the exploding gases is 1·22 : 1. The amount of nitrogen oxidised when mixtures of nitrogen, hydrogen, and oxygen are exploded is always less than when the ammonia which would be formed from these mixtures is exploded with the same ratio of oxygen.

PENANG HILLS RAILWAY.—The island of Penang consists of mountainous and broken country and is situated not far from the equator. The capital, Georgetown, is at sea-level, and the climate is trying for Europeans. It is therefore not surprising that a hill suburb is growing up on Penang Hills. Access to the summit has, until quite recently, been possible only by a tiresome and difficult journey by hill track some 5 miles long, and impossible for vehicles of any kind. A new railway was completed and opened on October 21 last year, the work having been carried out under the direction of Mr. A. R. Johnson of the Federated Malay State Railways. An illustrated account of this railway appears in *Engineering* for November 14, and the scheme has novel features. The total length is 1 mile 435 yards, and the upper station is 2381 feet above sea-level. In any funicular railway, the haulage engine has to move not only the cars but also the haulage rope, which may be considerably heavier than the useful load. The load on the engine is variable as the relative positions of the cars alter. The ideal arrangement is one in which the tractive force required from the haulage engine is a constant, and this effect is secured by making the profile of the railway a parabola. The Penang Hills Railway has been set out with a parabolic profile, and one of the striking features of the line is not only the practically constant loading of the haulage engine, but also the remarkably small power which it demands for its operation. The line is divided into two sections, and there is an electric-motor-driven winding engine at the top of each section. At the bottom of each section a short circular curve, tangential to the parabola, has been introduced. The object of this is to ease the starting grade so that the load does not rise above the normal during the period of acceleration. The total time for the journey to the top is about 25 minutes. The article is of interest also from the constructive point of view on account of the difficulties of the site.

A POCKET MICROSCOPE.—We have received through Messrs. Ogilvy and Co. (18 Bloomsbury Sq., W.C.), the British agents, an example of the new Leitz "Minor" folding microscope, which when folded is contained in a leather case only 6 in. long. Coarse focussing is by sliding tube and fine focussing by a screw collar encircling the tube. By means of a duplex combination lens, two eyepieces and the draw-tube, magnifications of from 50 to 250 diameters may be obtained. A low power objective can also be supplied giving magnifications of from 7 to 26 diameters. The folding foot may be so adjusted as to form a handle, so that with the low power objective the microscope may be used as a hand lens. The microscope is a handy little instrument, very suitable for field work or travel.

A NEW DEW-POINT HYGROMETER.—The issue of the *Physikalische Zeitschrift* for September 15 contains a short description of a dew-point hygrometer constructed by Dr. M. Holtzmann of the Geophysics Department of the Central Physical Observatory of Leningrad. A polished copper tube 2 cm. in diameter and 15 cm. long is placed with its axis vertical, and round its upper end is wound an insulated wire through which an electric current is sent so as to warm the upper end of the tube a few degrees above the temperature of the air. A short distance below the coil, a horizontal line is drawn round the tube and the two wires of a thermo-couple are soldered to the tube at points on the line. A stream of liquid at a temperature two or three degrees below the dew-point is then sent up the tube, and its speed so regulated that dew is deposited on the tube up to a point above the line. The stream is then stopped and the heating current reduced until the top edge of the deposit of dew descends to the line. The electromotive force of the thermo-circuit is then read on a galvanometer in circuit. The author claims that the instrument gives the dew-point with an accuracy of 0·02° or 0·03° C.

A NEW SPECTROMETER.—We have received from Messrs. Bellingham and Stanley, Ltd., of 71 Hornsey Rise, N., their catalogue of spectrometric apparatus, polarimeters, and refractometers, containing particulars of instruments suitable for many types of work. Particular attention is directed to a new model universal spectrometer, which may be used as a wave-length spectrometer for the visible and ultra-violet spectrum, a monochromatic illuminator, an infra-red spectrometer, a spectrograph, or, with the addition of the Bellingham and Stanley photometer, a high precision spectrophotometer. The instrument is arranged on the Littrow principle. Light from the slit is directed by a small totally reflecting prism to a concave mirror and thence to a 30° prism, from which it returns to the mirror and passes to a second slit, carrying an eyepiece adapter, by means of which the particular spectrum line required is isolated. The prism may be rotated so as to bring the required line into view. The prism and mirror inserted vary with the purpose for which the instrument is to be used. The photometer necessary to convert the instrument into a spectrophotometer has a number of new features in its design. The polarimeters, of which there are several models, consist of two solid components of Iceland spar mounted in such a way that no totally reflecting cement is required, and the risk of disintegration is reduced to a minimum by locating the sharp edge in one of the natural cleavage planes of the crystal. The refractometers include a high accuracy critical angle instrument specially designed to meet the objections to existing instruments working on the same principle.

Anniversary Meeting of the Royal Society.

THE report of the Council of the Royal Society, presented at the anniversary meeting on December 1, records that a bequest of 10,000*l.* has been received "for the prosecution of original research in medicine for the prevention of disease and relief of suffering with special attention to tropical diseases in British possessions and to cancer and tuberculosis." On the recommendation of the sectional committee for physiology, the subject of kala azar has been chosen for investigation, in view of its grave and increasing prevalence in India, and of the complete ignorance which exists as to the mode of infection. A further donation of 500*l.* has been received from Mrs. Tyndall, who in 1910 made a generous gift of 1000*l.* for the purpose of encouraging and furthering research in all matters pertaining to mining. It is the wish of Mrs. Tyndall that the income from this additional donation be used, at the discretion of the Tyndall Mining Bequest Committee, solely as a fund to meet out-of-pocket expenses incurred by the Tyndall research student in the carrying out of his investigations. The nineteenth and final volume of the Catalogue of Scientific Papers is now in the printers' hands. This contains about 44,200 entries under the letters T-Z, bringing the total number of entries for the period 1884–1900 to about 384,000. The publication of this volume will complete the great work of cataloguing the scientific papers of the nineteenth century. The first volume of this permanent record of the achievements of science during the period 1800–1900 was published in 1867. The cost of the catalogue has been very great, and might have prohibited the completion of the undertaking but for the assistance of the late Dr. Ludwig Mond and other donors, and for the generosity of the Syndics of the Cambridge University Press. Even apart from this assistance the total direct cost to the funds of the Royal Society has amounted to 24,970*l.*

President's Address.

In his address, Sir Charles Sherrington referred to the scientific careers and work of the twenty fellows, one foreign member, and one on the selected list of election as a fellow, who had died since the anniversary meeting of last year. He referred also to the original work on the emission of electrons from hot bodies carried out by Prof. O. W. Richardson, who was recently appointed to the third Research Fellowship founded by the munificence of Sir Alfred Yarrow, and to the retirement of Sir Arthur Schuster from the foreign secretaryship of the Society, after completion of the usual four years of office. The remainder of Sir Charles Sherrington's address is summarised below.

If I may finally pass for a moment to biological progress which the year has witnessed, I would advert to the work which Prof. Magnus and his collaborators have recently brought to approximate completion, their admirable research in nerve-physiology engaging the Utrecht laboratory during the past fifteen years. Its field has lain in nervous mechanisms which, though the highest part of the brain can have touch with them, can yet of themselves work wholly reflexly and separably from mind.

A number of simpler acts, studied for the most part in lowlier animal forms, have, of course, long been known to stand in that relation to the higher brain. But the Utrecht researches prove a like relation, and in the superior mammals, for acts surprisingly complex, the assumption and maintenance of the erect posture of walking, running, and so forth, in all their ordinary completeness. Not only have Magnus and his colleagues observed this, but they have also analysed the reflex processes by which these acts are thus accomplished. They have traced the seat and nature of the stimuli at work, the principles of the co-ordination of the nervous arcs and muscles involved, and indeed all the mutual interaction, which grade and secure the nicety of adjustment exhibited in such complexity.

Plant-growth orientates itself in regard to the line of gravity, geotropism; and so in the rabbit, cat, and monkey, standing, walking, running, with one element in common, the erect attitude, are shown by Magnus and de Kleyn to be, shortly said, refined geotropic reflexes. Any position other than the erect excites in the reflex animal restoration of its erectness. The head, for example, is righted by an act having its unconscious source in the pull and pressure of two microscopic stones in the special pair of tiny gravity organs bedded in the skull. With righting of the head goes rotation of the eyeballs in the opposite sense, keeping the vertical meridian of each retina in correspondence with the actual vertical. Appropriate reflexes bring the whole animal from any other position into the symmetrical right-side-up position. The well-known manœuvre which enables the cat, when inverted and falling from a short height, to right itself in the air during its fall, alighting squarely on its feet, is shown by Magnus and his colleagues to be executed perfectly by reflex action, after removal of the entire higher brain. Detailed analysis proves this whole reaction to be a chain of reflexes again essentially geotropic.

Following these researches we see, therefore, that it is less true to say that the higher animal under direction of its mind keeps itself right side up, than to say that the animal body by automatic mechanism is kept right side up. From the animal's point of view, as a sentient being, for it to be right side up to the world is, of course, for the world to be right side up to it. In other words, the body's automatism ensures that the mind looking, so to say, out from the body, finds the world right-side-up. By the Utrecht researches that relation is shown to be maintained by processes as non-mental as is digestive secretion of the bile. Hence, this right-side-upness being settled without mind, and indeed prior to mind, and naïve mind being, whatever else it is, utilitarian, the situation has not invited consideration from naïve mind. Mind has not needed, so to say, to think about a relation already existent and given it from the outset.

Prof. Magnus's researches enable us, therefore, to trace how, in the make-up of mind, right-side-upness of the world comes as an innate unargued datum, an immediate intuition, and therefore largely eludes mental analysis, there being no direct sense-experience of its origin or elemental processes, although confusion in mental space when its elements conflict. William James, with characteristic picturesqueness, wrote that our "prehistoric ancestors discovered the common-sense concepts," among them what he termed "one-space." With that we may set "world right-side-upness"; but as for dating its "discovery" to our prehistoric ancestors, it, as an immediate intuition, must date back not to the merely prehistoric but to the entirely prehuman.

Presentation of Medals.

The Copley Medal is awarded to Sir Edward Sharpey-Schafer. Sir Edward's work, extending from 1874 to the present time, has illuminated many parts of physiology, and the field of microscopical

anatomy no less. In 1894 he discovered, in conjunction with Dr. George Oliver, the remarkable effects of intravenous injection of extract of the adrenal gland, tracing their source to the small medullary portion of the gland. This research proved the starting point for a great volume of work, and was followed by somewhat similar work on another ductless gland, the pituitary, which opened a modern chapter of physiological knowledge of that organ, again with important consequences to medicine.

The Rumford Medal is awarded to Mr. C. V. Boys. Mr. Boys has advanced physical science by producing apparatus for accurate physical measurements and by making measurements of a high order of accuracy. He invented the first method for producing quartz fibres and investigated their elastic properties; he showed that they were practically free from fatigue, and demonstrated how admirably suited they were for the measurement of very small forces. He measured the extremely minute forces due to the mutual attraction of small masses, and he made a torsion balance of beautiful design for measuring the constant of gravitation. He took the first photographs of a bullet in flight and studied the wave disturbances produced by them, and has made a series of researches on soap bubbles and films. Recently he has developed a gas calorimeter which is the standard instrument prescribed by the gas referees for ascertaining the calorific value of the gas supplies of towns, work of special appeal in regard to a medal commemorative of Count Rumford.

A Royal Medal is awarded to Sir Dugald Clerk. In 1886, Sir Dugald described his experiments on the explosion of gaseous mixtures, providing data fundamental for the scientific development of internal-combustion engines. As chairman of the British Association Committee for investigation of gaseous explosions, he drew together workers concerned with the thermodynamics of internal-combustion engines who have contributed results of high importance. Sir Dugald himself investigated the effect of turbulence in a gas-engine cylinder and was successful in explaining the difference between the rate of combustion of the charge fired in a gas-engine cylinder in ordinary conditions of working, and the rate of combustion of the charge fired in a bomb. That to-day the internal-combustion engine is taking the place of steam power in smaller ships and in workshops as a prime mover of moderate power, and that to-day that engine renders possible the motor-car, the aeroplane and the submarine, is due largely to the scientific work of Sir Dugald Clerk.

A Royal Medal is awarded to Dr. Henry Hallett Dale. Working with successive collaborators, Dr. Dale showed that histamine, an amine derived from ergot, produces a condition resembling wound shock and toxæmic collapse. By analytic experiments he succeeded in establishing that histamine, while causing spasm of arterial and visceral muscle, conversely paralyses the active contraction of the capillary blood-vessels; and this analysis was reached at a time when the property of contractility of those vessels had not been generally recognised. He showed that their paralysis is the dominant feature in the shock and is responsible for a virtual break-down of the whole blood circulation. He has shown further that in histamine "shock" we have a paradigm for the shock effect of a large class of protein poisons, and also for the grave condition known in medicine as secondary surgical shock, toxæmic collapse, and anaphylactic shock.

The Davy Medal is awarded to Prof. A. G. Perkin. Prof. Perkin is distinguished for his researches on the natural organic colouring matters. During the course of his researches on luteolin, morin, apigenin, quercitrin and other flavone compounds, he discovered and investigated certain derivatives which such dyestuffs form with acids—substances which he was able to employ for determining the molecular weights of these colouring matters. His classical researches on natural indigo have left few questions unanswered as regards the chemical constitution and behaviour of this important product, and he was the first to show that one of the constituents—indirubin—played no part during the process of vat dyeing with this agent. He was also the first to prepare in large quantity crystalline indican—the essential glucoside of natural indigo—and to study its properties. More recently he has investigated other natural products, notably the colouring matter of cotton flowers, and has dealt with the formation and structure of the important vat-dyes derived from benzanthrone.

The Darwin Medal is awarded to Prof. T. H. Morgan. Prof. Morgan's studies on polarity, on fertilisation, and later on gynandromorphism and sex determination, mark distinct advances in knowledge. The discovery of two kinds of spermatozoa in phylloxera and observations on chromosomes in these and other insects helped to elucidate the nature of the determination of sex in parthenogenesis. Of late years he has devoted himself to the study of heredity in various animals, and especially in the fly, Drosophila. The results obtained by him and his collaborators have thrown light on the relation of the factors of heredity to the chromosomes, on sex-linked and sex-limited characters, and other difficult problems in heredity.

University of Leeds.

TRIBUTE TO PROF. A. SMITHELLS, C.M.G., F.R.S.

THE movement which was set on foot some time ago for signalising the distinguished services of Prof. Smithells to the University of Leeds, and in other directions, reached its culminating point on November 25, when a portrait of Prof. Smithells, painted by Mr. Fiddes Watt, A.R.S.A., was presented to the University at a ceremony held in the Great Hall. At the same time, it was announced that the fund had reached the sum of 2462*l.* 6*s.* 11*d.*, of which approximately one half had been contributed by the gas industry, to which Prof. Smithells had been able to render such distinguished service.

The proceedings were opened by the pro-chancellor of the University, Mr. E. George Arnold, who spoke in the warmest possible terms of what Prof. Smithells had done during his 38 years' tenure of the chair of chemistry not only as professor of that subject but also in connexion with the wider matters of policy which the University had had to face at the time of its foundation and in the years that followed.

Mr. Arthur Lupton, who was pro-chancellor of the University during most of the long period of Prof. Smithells' service, presented the portrait on behalf of the subscribers, who numbered more than 800. He was followed by Prof. J. W. Cobb, who supported Mr. Lupton in the presentation and spoke as an old student of Prof. Smithells and a colleague in the Senate and on the Board of Science and Technology. He pointed out that when it was decided to make Leeds a centre of university education, not merely was it that a new university was instituted but a new kind of university. Its distinguishing mark was that not only was science to have a place of honour, but that a Faculty of Technology was to be created

in the University to rank along with the other Faculties of Art, Science, and Medicine, and to live alongside them in the closest intimacy. To do this effectively required judgment, imagination, and particularly courage and the faculty of dealing wisely with men and affairs. Prof. Smithells had written and spoken on this subject but always impersonally. On this occasion it was only proper that prominence should be given to the personal aspect, and the dominating part played by Prof. Smithells in this work fully and freely acknowledged.

Further support came from Prof. B. M. Connal, speaking as an old Arts colleague, and from Mr. J. Ferguson Bell, the president of the Institution of Gas Engineers, who, speaking for the gas industry, acknowledged the great indebtedness which they felt to science in application to their industry and particularly to the work of Prof. Smithells and the University of Leeds.

The portrait was received by the vice-chancellor on behalf of the University.

Prof. Smithells then described how his scientific work on flames had brought him into contact with the gas industry and its problems, and acknowledged, in impressive terms, its generosity to the University and the honour now paid to him. Referring to his colleagues, past and present, he paid a tribute to the founders of the old Yorkshire College and the remarkable group of men of science—Green, Rucker, Thorpe, and Miall—who in the early years so successfully disseminated the right spirit in the young institution, which ensured its initial success and later progress. To the late Prof. L. C. Miall he expressed a special personal tribute and the belief that no man did more for the spirit of the College and University. Speaking of the scholarship to be founded with the funds subscribed, he had wondered for a moment whether unity of knowledge might not receive appropriate illustration by devoting it to some literary end, but the idea was no doubt somewhat fantastic in this connexion. After all, he believed in science and shared the conviction expressed by a great man of letters, Mr. Galsworthy, that the future of the race was in the hands of science. It was right and proper, therefore, that this scholarship should be devoted to its advancement. In complimenting Dr. Baillie on his appointment as vice-chancellor, he assured him of a generous welcome, and expressed a firm faith in the modern university.

It was announced that the Smithells Fund would allow, after payment of the portrait and incidental expenses, of the establishing of a scholarship bearing the name of Prof. Smithells, within the University, of approximately 100*l.* per annum.

The British Dirigible Programme.

THE decision to take up again the development of dirigibles in Great Britain has probably been influenced by the example of the United States.

The following table gives a basis of broad comparison with German craft:

Name.	Length.	Diam.	Volume.	Displacement.	Power.	Speed.	Length/Diam.
	m.	m.	cub. m.	tons.	k.w.	km./hr.	
R 101 .	220	39·9	143,000	165	7×430	115 est.	5·5
"Burney"	212	40·5	143,000	165	7×430	115 est.	5·25
ZR 3. .	203	28	70,000	81	5×300	140 max.	7·25
L 59 . .	226·5	23·9	68,500	79	5×180	131 max.	9·5
Bodensee	121	18·7	20,000	23	4×180	135 max.	6·45

German practice shows much greater ratios of length/diameter; in the case of the L 59, this was perhaps due to the greater ease with which existing airsheds can be increased in length than in height and width; but the *Bodensee*, a successful post-War commercial craft, and the ZR 3, the latest example of German design, were free from this restriction.

In passing from the ZR 3 to the R 101 and the "Burney" the volume and power are both doubled, so that with similar shapes there should be an increase in speed of about $2^{1/9}=1{\cdot}08$, or from 140 km./hr. to 151 km./hr., as compared with 115 km./hr., which is a heavy margin in estimating. The shapes are, however, very different.

Tests at the National Physical Laboratory on relatively minute models in the wind-tunnel indicate a "best" ratio of length/diam. between 4·5 and 6. Presumably the British designers are not relying solely on a very doubtful aerodynamical similarity, and it would be interesting to know the full size data on which they are departing so boldly from German practice.

The United States naturally hold for themselves the only supplies of helium, and the best method open to other nations for reducing fire risks is by installing heavy oil engines as is specified for the new British craft. The specification of "stainless" steel for the metal framework indicates a surprising advance in the design of members to resist local buckling in the very thin webs and flanges as compared with lighter and bulkier duralumin.

In a previous note (NATURE, October 11, p. 548), the useful life of a dirigible was estimated from German records as less than two serious voyages per month for eighteen months, excluding fire and war risks. It remains for time to show how far the ZR 3 in American hands, and the new British craft in British hands, will compete with this standard of performance set up by the Germans after more than twenty years' experience.

No doubt it is difficult for the authorities to neglect completely a potential weapon, even though the aeroplane has proved an almost perfect antidote. From this point of view alone, their decision is entirely defensible. The long delay in coming to it may well be explained by the formidable nature of the problem taken as a whole.

University and Educational Intelligence.

CAMBRIDGE.—The time having lapsed during which the University can suspend the Jacksonian professorship of natural philosophy, and no new scheme for it having been adopted by the University, the Vice-Chancellor has declared that the professorship is vacant. An election will take place on January 5 next.

Mr. F. Balfour Browne, Gonville and Caius College, has been appointed University lecturer in zoology.

LONDON.—The title of professor of anatomy in the University has been conferred on Mrs. M. F. Lucas Keene, in respect of her post as head of the Department of Anatomy at the London School of Medicine for Women. Prof. Lucas Keene was appointed lecturer in anatomy and embryology, with charge of the department, at the London School of Medicine for Women in 1919, and the title of reader in anatomy in the University was conferred on her in respect of this post in 1921.

A course of free public lectures on "The Anatomy and Physiology of the Sympathetic Innervation of the Striated Muscle" will be given at University College, at five o'clock on December 8, 10, and 12, by Prof. J. I. Hunter, of the University of Sydney. No tickets will be required.

Applications are invited for the chair of pathology at the London (Royal Free Hospital) School of Medicine for Women. Twelve copies of each appli-

cation should be received by, at latest, the first post of January 29 by the Academic Registrar, University of London, South Kensington, S.W.7.

APPLICATIONS are invited by University College, Nottingham, for a lectureship in psychology. The person appointed will take charge of the psychological laboratory and be expected to assist in the teaching of philosophy. Forms of application (returnable not later than December 10) can be obtained from the registrar.

A FULL-TIME male teacher of chemistry is required at the Northern Polytechnic Institute, Holloway, N.7, with a knowledge of the application of chemistry to the building and rubber trades. Candidates must be university graduates, preferably with honours degrees. Application forms are obtainable from the Secretary of the Institute.

IT is stated in the *Chemiker Zeitung* that two newly created professorships in the medical faculty of the University of Münster have been filled by the appointment of Dr. Heinrich Többen to the chair of forensic medicine, and of Dr. Hermann Freund, of Heidelberg, to the chair of pharmacology.

PROF. W. H. MOBERLY, professor of philosophy in the University of Birmingham, has been appointed principal of University College of the South-West, Exeter, in succession to Principal Hetherington, who is becoming professor of philosophy in the University of Glasgow.

THE Leeds University Calendar for 1924–25 refers to the jubilee celebrations which will take place during the week December 15-20. Fifty years have elapsed since Yorkshire College was established as a College of Science, and forty since it was united with the Leeds School of Medicine, founded in 1831. The College formed part of the Victoria University, Manchester, from 1887 to 1904, when the University of Leeds was established by Royal Charter. The new Calendar, unlike previous issues, gives no particulars of the staff.

THE *Educational Record*, published quarterly by the American Council on Education, gives in its July number an interesting series of reports on the various activities of the Council and its committees during the past year. Like the Standing Committee of Vice-Chancellors in Great Britain, it was formed under the stress of war-time conditions, and has steadily grown during the past six years in importance. It is now the most influential voluntary body for the promotion of the interests of education in the United States. Some idea of the scope of its work can be gathered from the following list of subjects dealt with by its several committees: educational finance, federal legislation, college and university personnel, foreign language teaching, Franco-American exchange, international educational relations, foreign travel and study, college standards. The Director classifies the Council's activities under five main headings—standards, personnel, national relations, international relations, and research. It is his special care to ensure that work done under each of these heads is guided so as to contribute most fully to the advancement of the work in progress under the other heads. One of the most important of the Council's enterprises is the "Division of College and University Personnel" created two years ago for compiling a perpetual register of college teachers, their academic careers and qualifications, for the whole of the United States.

THE annual meeting of the Geographical Association will be held on January 1-3 at the London School of Economics, and arrangements have been made for members to travel to the meeting at reduced railway fares. Prof. J. L. Myres will deliver his presidential address on "A Geographical View of the Historical Method in Ethnology" on January 2, and he will also broadcast a message on "Wayside Geography" on the previous evening. Included among the numerous illustrated lectures which will be given is one by Mr. R. U. Sayce, of the Department of Geography, Natal University College, on aspects of the human geography of Natal. On January 1, a discussion, to which all university teachers of geography are invited, will be opened by Prof. J. L. Myres on "Departmental Research Programmes," while on the next day there will be a symposium on the life of fiord people, at which Dr. A. Sommerfelt (Kristiania), Mr. Henry Balfour (Oxford), Mr. C. E. P. Brooks (Meteorological Office), and Mr. C. B. Fawcett (Leeds) will speak. January 3 is to be devoted to special sessions on the teaching of geography. The first discussion, on school geography, will be opened by Mr. S. W. Rider (Gowerton County School) and Capt. T. K. Mortimer Booth (Christ's Hospital). At midday, four simultaneous discussions will be held: on the beginnings of geography, the teaching of climate, home geography, and school geography clubs and journeys. The afternoon will be devoted to excursions to various parts of London, including a party under the leadership of Mrs. Ormsby to beat the bounds of the City of London. On the first two days of the meeting a publishers' exhibition of books and maps will be open. Further particulars of the meeting can be obtained from the secretary of the Association, 11 Marine Terrace, Aberystwyth.

"CONTINUITY" was the text of a speech by the president of the Board of Education at the annual dinner of the London Teachers' Association on November 29. He hoped that in the coming year careful surveys of the field of education would be made by local authorities with the view of framing comprehensive schemes of development. Such a scheme has just been drawn up by the West Riding Education Committee providing for new capital expenditure during the years 1926 to 1932 on sites, buildings, and equipment, of 1,000,000*l.* for elementary, 543,000*l.* for secondary, and 300,000*l.* for technical education, entailing maintenance charges of 270,000*l.* per annum. Among the improvements aimed at are: (1) the reduction in size of classes (at present 946 classes contain more than 50 and 1332 from 41 to 50 children each); partly by means of (2) Central Schools in which adequate provision, impossible under present conditions, will be made for (3) instruction in handicraft and domestic subjects; (4) increasing the proportion of attendance at secondary schools from 9·5 to 15 per thousand of the population; (5) to provide for technical and other forms of further education 84 new schools and 10 enlargements or replacements. Under the last-mentioned head are included not only technical schools in buildings provided for the purpose or used jointly as secondary or middle schools, but also technical classes with "facilities for practical work in Science, Manual Training, Cookery, History, Social Science, Pure Natural Science, Botany, Entomology, etc., that might suitably be incorporated in the buildings of a Central School or a Central Top for a group of elementary schools." The annual additional charge on the rates, assuming that the capital is to be borrowed, will, it is estimated, amount to 6*d.* in the pound on the basis of existing assessable values.

Early Science at the Royal Society.

December 6, 1677. Dr. Croune related, that Sir Peter Colleton had taken care to send several baroscopes to Barbados, in order to examine, whether they would be of any use for the foretelling the seasons and mutations of the weather as they are found to do in England especially concerning hurricanes.—The president inquiring what experiments were designed for the next meeting, Mr. Hooke undertook to have the hydrostatical experiment ready; as also a farther improvement of the microscope. It being late the Society rose, and waited on the president to his own house.

December 7, 1664. It being suggested, that there were several persons of the society, whose genius was very proper and inclined to improve the English tongue and particularly for philosophical purposes; it was voted that there be a committee for improving the English language; and that they meet at Sir Peter Wyche's lodgings in Gray's-Inn.

December 8, 1670. Monsr. Andreas Monceaux, a French gentleman and a great traveller, son to Monsr. Monceaux, counsellor to the most Christian King, and great audiencier of France was proposed candidate.

December 9, 1663. The experiment of trying the force of powder by weight in the new powder engine contrived by Mr. Hooke was made twice, but without success both times; once by reason that the barrel broke in pieces; the second time, because the cover of the barrel bent. It was referred to Mr. Hooke to think of a way to prevent the inconveniencies.

1667. Sir Anthony Morgan and Mr. Hoskyns reported concerning the legal validity of the obligation subscribed by the fellows of the society; that the statutes had already specified the penalty for non-observance, viz., expulsion; and that thereby other penalties were excluded.

1669. Mr. Hooke produced another specimen of staining with yellow, red, green, blue and purple colours; which he said would endure washing with warm water and soap.

1675. There was produced a manuscript of Mr. Newton, touching his theory of light and colours, containing partly an hypothesis to explain the properties of light, partly the principal phenomena of the various colours exhibited by thin plates or bubbles, esteemed by him to be of a more difficult consideration.

December 10, 1662. The experiment of purging water from air, to see whether it subsides, according to the Torricellian experiment was deferred till the next meeting, because the engine was not tight.—Dr. Croune brought in some account of the breaking of wires; the experiment whereof appearing as yet very uncertain, he was desired to prosecute the same by trying several wires of different matter, and the same size, to see, whether the proportion of toughness in different metals may be found.

1668. A letter of Dr. Wallis contained an answer to some queries of Mr. Neile, viz., 1. Whether quiescent matter have any resistance to motion. 2. Whether motion may pass out of one subject into another. 3. Whether no motion in the world perish. 4. Whether different motions meeting destroy one another. Ordered to be entered.

December 12, 1678. Mr. Povey presented to the Society for their library a small stitched book in 4to. containing an history of Chelsea College.—He presented likewise, the claw of a West India spider, very much resembling the claw of a lobster or crab; given him by the Lord Willoughby of Parham as a present remedy against the tooth-ache.

Societies and Academies.

LONDON.

Optical Society, November 13.—T. **Smith**: (1) The theory of neutralisation. According to the new theory which is propounded, the test should be made with the lenses midway between the test object and the observer's eye, and the connexion between the vertex powers of the lenses when neutralisation is exact involves the distance of the test object and the order in which the lenses are placed. The simple law of the zero sum for the vertex powers is attained with simple accuracy as a mean result, the combination of high-powered lenses of equal and opposite vertex powers appearing as a positive lens from one side and negative from the other. The theory leads to the suggestion that in practice plano-lenses should be tested with their plane, not their curved, surfaces in contact. (2) The back vertex power of a combination of lenses. The general relations between the constants of a compound instrument and those of its components are obtained when the imagery is collinear. From these relations the expression for the vertex power of a compound instrument is built up in the form convenient for application in spectacle and other calculations.—R. **Kingslake**: A new type of nephelometer. The instrument provides an accurate optical method of measuring a minute amount of precipitate by means of the turbidity it produces in solution. Light is passed into the end of a tube containing the solution, and the intensity of the scattered light is measured by a special form of wedge-photometer.—A. **Pollard**: A note on nephelometry. The nephelometer described above is capable of measuring such minute quantities as the amounts of the oxides of nitrogen evolved from explosives in unit time under normal temperature and pressure.

Physical Society, November 14.—W. H. **Eccles** and C. F. A. **Wagstaffe**: An electrical method of producing vowel sounds and its application to wireless telegraphy. Apparatus has been devised to test a proposed method of communication in which the electric waves transmitted could produce easily recognisable chords at a suitably equipped receiving station. It was thought that chords would be more easily recognised than simple tones, and that vowel sounds would be the most easily recognised of chords. The ideal aimed at in this method of communication is that an operator at one side of the ocean should converse with an operator at the other side by means of a language made up of vowel sounds (somewhat like the Hawaiian language), the sounds being produced by pressing keys. Any ordinary language could be converted immediately into this telegraphic language by a code wherein each consonant was represented by a definite pair of vowel sounds.—D. W. **Dye** and L. **Hartshorn**: The dielectric properties of mica. Practically all samples of muscovite (potassium mica) have the same dielectric constant, the most probable value being 7·0. The presence of inclusions has no great effect on this value. The samples of phlogopite (magnesium mica)—*i.e.* the amber micas—have rather lower dielectric constants, about 6·0 for normal amber mica, and 5·0 for the silver amber variety. For the clear micas (muscovite) the power factor may be so low as 0·0003, and possibly less. The effect of inclusions is to increase it considerably. The power factor of the amber micas is greater than that of the muscovite variety—about 0·02 for the clear amber and 0·05 for the silver amber variety. The samples were all about 8 cm. square and 0·1 mm. thick, and the measurements were all made on the Carey Foster bridge at a frequency of 800 cycles per

second.—L. **Simons**: The X-ray emission of electrons from metal films, with special reference to the region of the absorption limit. Barkla and Miss Dallas have shown how the total energy of the β-rays from silver (as measured by the ionisation produced in H_2) varies with wave-length as the region of the K absorption limit is crossed. The author has now determined directly the aggregate number of β-rays of all types emitted over the same range; no selective change in the average energy occurs when the K fluorescent spectrum is excited. This is brought about by a re-grouping amongst the numbers and energies of the β-rays constituents, together with the addition of the K group of minimum individual energy. The experimental work has necessitated the separation of the β-rays from the secondary effects they produce, the chief of which is the production of δ-rays of very low energy. The δ-rays seem to be impact electrons the most frequent energy of which is little greater than 3·5 volts; this seems to be independent of the wave-length producing them, and of the substance from which they come. There are indications that they are influenced, at the moment of their departure from the surface, by the scattered X-rays.

PARIS.

Academy of Sciences, November 10.—M. Guillaume Bigourdan in the chair.—A. **Lacroix**: Remarks on the dissogenites, with reference to Colorado evergreenite.—G. **Bigourdan**: Observation of the occultation of Mars by the moon on November 5, 1924. The times of the second and fourth contacts are given. The sky was clear, but the atmospheric conditions were not good.—Armand **Cahen**: Developments proceeding according to f functions indefinitely superposed and arranged in descending chain.—A. **Bloch**: Functions taking several times the values 0 and 1 in a circle.—E. F. **Collingwood**: Some theorems of M. R. Nevanlinna.—Arnaud **Denjoy**: The singularities of series of rational fractions.—M. **Lyot**: The polarisation of the planet Saturn. It has been shown in earlier communications that light from the moon, Mars, and Mercury is polarised; the polarisation caused by Venus appears to be due to clouds, whilst that of Jupiter is partly due to clouds and partly to an atmosphere. Observations on Saturn made in May and June 1922, April, May, and June 1923 and 1924. The ring and the planet showed different polarisation phenomena, and the results are shown separately on a graphical representation of the results.— — **Giacobini** and — **Fatou**: Observations of Baade's planet, made at the Paris Observatory. Four positions are given on November 6, 7, and 8, together with the positions of the comparison stars. At present this planet is of 9·3 magnitude.—Ferdinando **Gazzoni**: An attempt at the quantitative estimation of thorium-X. In the presence of thorium, after precipitation by hydrogen peroxide, the filtrate contains thorium-X and its active deposit: in the presence of aluminium, after precipitation by ammonia, only thorium-X is found in the filtrate.—Paul **Pascal**: The definition and preparation of the hexametaphosphates. On the basis of cryoscopic and electrical conductivity measurements, and in view of the existence of a sodium lead salt ($Pb.Na_4(PO_3)_6)_2$, Graham's salt is regarded as a complex hexametaphosphate of the constitution $Na_2(Na_4(PO_3)_6)$.—E. **Burlot**: The determination of the theoretical energy and the co-volume of explosives.—Henry **Le Chatelier**: Observations on the preceding communication of E. Burlot. In experiments made forty years ago (with Mallard) the authors calculated some specific heats. The experiments in the preceding paper show the necessity of modifying these figures, which were probably 10 per cent. too high.—Claude **Fromageot** and René **Wurmser**: The comparative adsorption of some organic acids and their sodium salts. The adsorption by charcoal of formic, acetic, propionic, oxalic, succinic, citric and pyruvic acids from aqueous solutions was determined and compared with the adsorption of their sodium salts from solutions of the same concentration. No simple relation was found between the adsorption of the different groups and the dissociation constant of the acids to which they belonged. The salts are always less adsorbed than the corresponding acids.—L. J. **Simon**: The conditions of application of the technique for the estimation of carbon by the argentosulphochromic method. Experiments showing the relation between the amount of silver bichromate used in the analysis and the time required for complete combustion are recorded.— — **Tiffeneau**, A. **Orékhoff**, and Mlle. J. **Levy**: The isomerisation of the ethylene oxides with migration. The mechanism of molecular transpositions. Trisubstituted ethylene oxides of the type $Ar.CH.C(RR)$ can be isomerised under the influence of heat, giving rise to the corresponding aldehydes $Ar.C(RR').CHO$. It is certain that in this case the migration of the aromatic group cannot be the initial change.—Marcel **Delépine**: The structural relations between the pinenes and the terpineols or the limonenes derived from them.—J. **Barthoux**: The pyrites of Maïdan-Peck (Serbia).—Mme. A. **Hée**: The frequency of earthquakes in Algeria during the ten years 1911-1920.—Marcel **Mirande**: The optical properties of the sterinoplasts and of the phytosterin of the bulbs of the white lily.—René **Souèges**: The embryogeny of the Euphorbiaceæ. The development of the embryo in *Euphorbia Esula*.—Marc **Bridel**: The hydrolysis of monotropitine by a ferment. The production of primeverose. The products of hydrolysis of monotropitine (extracted from *Betula lenta*) by an enzyme extracted from *Monotropa hypopitys* were methyl salicylate and the reducing sugar, primeverose. The latter was obtained crystallised and was proved to be identical with the primeverose obtained from gentiacauline and from the glucosides of *Primula officinalis*.—J. **Beauverie**: The germination of the uredospores of the rust of wheat.—E. **Leblanc**: The orbital muscles of reptiles. Study of the muscles in *Chameleo vulgaris*.—M. **Javillier**, P. **Bauer**, and Mlle. S. **Levy-Lajeunesse**: Attempts at the identification of the factor A. The factor A and phytol. The unsaponifiable fraction of chlorophyll, consisting mainly of phytol, has many properties in common with the liposoluble factor A, but experiments on rats proved that phytol has not the action of factor A.

COPENHAGEN.

Royal Danish Academy of Science and Letters, October 17.—C. **Wesenberg-Lund**: Contributions to the anatomy and biology of the genus Zoothamnium. The biology and anatomy of Z. *geniculatum* has been studied during two years. Special attention has been paid to the so-called macrogonidia, their origin and their significance for the formation of new colonies.

October 31.—Johannes **Fibiger**: Vilhelm Ellermann. His life and scientific work.—Niels **Nielsen**: Note on Lagrange's series. The name of Bürmann has been given to some series of Lagrange, but the supposed memoir of Bürmann does not exist. Research on a new series of Lagrange.

VIENNA.

Academy of Sciences, June 12.—F. **Werner**: Scientific results of the Treitl bequest zoological expedition to the Anglo-Egyptian Sudan, Kordofan, 1914. Odonata, compiled by F. Ris, including descriptions of two new species.—H. **Spandl**: Freshwater amphipodes, especially those of the Baikal and Caspian Seas, and the relation of the Caspian Sea fauna to that of the Arctic and Baltic.—V. **Brehm**: Descriptions of new Entomostraca from the Handel-Mazzetti expedition to China.—E. **Dittler** and A. **Köhler**: Experiments on potassium-sodium felspars. Perthite was heated at temperatures below the melting-points of its components. Thin sections about 0·02 mm. in thickness were used; an alteration of optical constants as seen through the microscope proved diffusion in the solid state. An electrical resistance furnace allowed a temperature of about 1000° C. to be maintained for 500 hours. Albite and orthoclase can diffuse into each other forming mixed crystals.

June 20.—F. **Kerner-Marilaun**: The solar-climatic temperatures of antiquity.—H. **Handel-Mazzetti**: New Chinese plants described, including species and varieties of Juniperus, Camellia, Schima, Lobelia, Leontopodium.—L. **Kölbl**: Tectonic of the granite peaks in the High Tauern.

June 26.—R. **Kremann** and R. Gruber-**Rehenburg**: Electrolytic conduction in fused metal alloys, copper-zinc, copper-tin, copper-silver, and copper-aluminium.—R. **Kremann** and O. **Benda**: The electrolysis of silver-lead alloys.—R. **Kremann** and H. **Drazel**: On the influence of substitution in the components of binary solution equilibria. Equilibrium diagrams for benzhydrol with phenols and amines.—E. **Müller**: Calculating with fold-products as applied to three-dimensional objects of the second order.

July 3.—E. **Lohr**: Continuum theory of Röntgen ray propagation in crystals.—H. **Handel-Mazzetti**: New Chinese plants.—I. **Pia**: The diplopores in the Trias of Southern Dalmatia.—E. **Hofmann**: Plant remains from the lake-dwellings of Mondsee.

July 10.—E. **Philippi** and R. **Seka**: On the dinaphth-anthracene series. VI. Condensation of pyromellithic acid anhydride with decaline and tetraline. VII. Sulphonation of di-naphth-anthracene-di-chinon. VIII. Substituted derivatives of pyromellithic acid. Some aliphatic polycarbon acids.—J. **Korczyn**: On the irregularities in the β-radiation of freshly crystallised uranyl nitrate.—G. **Ortner** and H. **Pettersson**: On the preparation of radium C II.—G. **Kirsch** and H. **Pettersson**: On the disintegration of atoms by α-rays (II.). A method for observing atomic fragments of short range.—H. **Pettersson**: On the disintegration of atoms by α-rays (III.). The disintegration of carbon. Bombardment by α-radiation gives H- and α-particles, the latter with a range of about 10·5 cm. The ranges of the H-particles at right angles to, and in the direction of, the primary radiation were 16 cm. and 8 cm. The results were in agreement with an explosive mechanism for atomic disintegration.—G. **Kirsch**: On the disintegration of atoms by α-rays (IV.). Disintegration of nitrogen and oxygen; helium a product. When fast α-rays traverse nitrogen, both H-particles and secondary α-rays arise. α-particles were also obtained from oxygen. The collisions of swift α-particles with light atoms yield hydrogen and helium as disintegration products.—H. **Handel-Mazzetti**: New Chinese plants. The descriptions of new Chinese Primulas collected by the Handel-Mazzetti expedition are continued. Six new primulas are described, some from 10,000 feet and higher in the mountains of the provinces Yunnan and Setschwan.—F. M. **Exner**: Monthly anomalies of atmospheric temperature and pressure on the earth; correlation of the pressure in Iceland with the pressure in other places.—O. **Dafert** and J. **Höfinger**: Chemical investigations of the deposits from the Dragon Cave near Mixnitz in Styria.—R. **Kremann** and J. **Dellacher**: Electrolytic conduction in fused metal alloys (IX.), tin-aluminium alloys.—M. **Kohn** and M. **Weissberg**: On *m*-bromophenol (VII.).—G. **Weissenberger** and L. **Piatti**: Molecular compounds of phenols (II.). The behaviour of cresols with aromatic hydrocarbons.—G. **Weissenberger** and H. **Waldmann**: On absorption from viscous fluids by charcoal.—R. **Seka**: On 8-amido-chinolin and derivatives.—F. **Kautsky**: The more recent folding in the eastern Alps and its expression in the gravity diagram.—L. **Moser** and R. **Lessnig**: The identification and separation of rare metals from other metals (V.). The separation of zirconium and hafnium from titanium, cerium, and thorium.—A. **Brukl**: The preparation of metallic tellurides from tellurium hydride and metallic salt solutions.

October 9.—H. **Kurtz**: A revision of the genera Lernæogiraffa and Doryphorus, parasitic copepods inhabiting the gills of a fish Heterotis in the river Nile.—F. **Querner**: The head and mouth parts of the African fly, *Diopsis apicalis*.

October 16.—A. **Tauber**: Some properties of algebraic functions.—E. **Dittler** and A. **Köhler**: The behaviour of felspars at high temperatures. Continued investigations of perthite.—G. **Weissenberger** and F. **Schuster**: Molecular compounds of phenols (III.). The behaviour of binary systems with hydrated phenols.—A. **Kailan** and H. **Raupenstrauch**: The esterification of fatty acids in glycerin, with a formula for the coefficient of velocity.—**F. Hochstetter**: On cases of total absence of septum pellucidum in man.

WASHINGTON.

National Academy of Sciences (Proc. Vol. 10, No. 9, September).—H. **Bateman** and P. **Ehrenfest**: The derivation of electromagnetic fields from a basic wave-function.—Alice H. **Armstrong**, W. **Duane** and W. W. **Stifler**: The influence on secondary X-ray spectra of placing the tube and radiator in a box. The X-ray tube and secondary radiator were placed inside a lead-lined wooden box, the back of which could be removed. Evidence was obtained of scattered radiation due to the Kα doublet of the molybdenum, but on removing the back of the box the form of the spectrum changed. It is suggested that the secondary and tertiary radiation inside the box may mask completely the effect of the secondary radiator under examination.—S. K. **Allison**, G. L. **Clark** and W. **Duane**: The influence on secondary X-ray spectra of placing the tube and radiator in a box. In these experiments a wooden box was used. Radiation with increased wave-length was obtained, agreeing with Compton's observations and also with the suggested tertiary radiation, but of carbon and oxygen. Removing the secondary radiator (a plate of sulphur), but retaining the wooden box, decreased the intensity of the spectrum without changing its character. If the box was removed and the secondary radiator retained, the character of the spectra changed.—B. **Davis** and R. von **Nardroff**: Further experiments on the refraction of X-rays in pyrites. In earlier experiments the characteristic K radiation of molybdenum was used; the K characteristic radiation from copper is now employed and as before (NATURE, April 26, p. 627) the results are in good accord with figures derived from the Lorentz dispersion formula. This formula seems to be valid for X-radiation.—K. K. **Smith** and L. I. **Bockstahler**:

An improved method of measuring the specific heats of metals at high temperature. A positively charged molybdenum cylinder surrounds a tungsten filament which acts as a thermionic emitter, and the whole is heated in a furnace. The changes in the thermionic current are measured by an oscillograph. The specific heat of tungsten at 2375°-2475° K is 0·045 cal. per gm. and the atomic heat 8·3 cal. per gram-atom.—C. E. **St. John** and H. D. **Babcock**: Note on the pressure and currents in the sun's atmosphere. Gathering up the observations of different workers during the past few years, a chart is constructed showing a scheme for the distribution of factors in the sun's atmosphere according to level.—C. E. **St. John** and W. S. **Adams**: Convection currents in stellar atmospheres. High dispersion spectrograms of Sirius, Procyon, Arcturus and the sun show close agreement between the differences enhanced minus arc lines and high- minus low-level lines, both differences being apparently due to variation in convection currents with level. Convection currents seem to increase with temperature. The pressures in the atmospheres of all these stars are low and of the same order.—E. B. **Wilson** and W. J. **Luyten**: A statistical discussion of sets of precise astronomical measurements (III.); masses of the stars. The distribution of the logarithm of the mass of the stars is very close to normal—closer than might be expected from the meagre data. Systems with unusually big masses are not included.—T. R. **Hogness** and E. G. **Lunn**: The ionisation potentials of hydrogen as interpreted by positive ray analysis. Hydrogen is ionised by impact electrons from a tungsten filament, and the positive ions are drawn into a magnetic field where they are analysed. Three positive ions were found, H^+, H_2^+ and H_3^+, the H_2^+ ions predominating; no negative ions were detected. To determine the ionisation potentials, the voltage of the impact electrons was decreased by steps from a maximum until no ions were detected. The values obtained were: H^+, 16·6 volts; H_2^+, 15·7 volts; H_3^+, 16·7 volts.—G. E. M. **Jauncey** and H. E. **Stauss**: The polarising angle for X-rays scattered by paraffin. A shift of the polarising angle was observed according qualitatively with Jauncey's equations for a corpuscular quantum theory of the scattering of polarised X-rays.—R. G. **Dickinson**: The combination of hydrogen and oxygen in the presence of activated mercury. Hydrogen and oxygen in a quartz reaction tube were exposed to a blast of air from a mercury lamp; the pressure decreased steadily, apparently owing to the formation of water.

Official Publications Received.

Smithsonian Miscellaneous Collections. Vol. 75, No. 2: Cambrian Geology and Paleontology, V. No. 2: Cambrian and Lower Ozarkian Trilobites. By Charles D. Walcott. (Publication 2788.) Pp. 53-66. Vol. 76, No. 11: The Freshfield Glacier, Canadian Rockies. By Howard Palmer. (Publication 2757.) Pp. 16+9 plates. Vol. 77, No. 1: A Chapter in the History of Zoological Nomenclature. By Leonhard Steineger. (Publication 2789.) Pp. 21. (Washington: Smithsonian Institution.)

Department of the Interior: Bureau of Education. Bulletin, 1924, No. 3: An Evaluation of Kindergarten-Primary Courses of Study in Teacher-Training Institutions. By Nina C. Vandewalker. Pp. iii+44. (Washington: Government Printing Office.) 5 cents.

Diary of Societies.

SATURDAY, DECEMBER 6.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10 A.M.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.), at 3.—E. W. H. Piper: Durham Cathedral (Lecture).

INSTITUTE OF BRITISH FOUNDRYMEN (at Chamber of Commerce, Birmingham), at 4.—D. Wilkinson: Malleable Iron.

MONDAY, DECEMBER 8.

ROYAL IRISH ACADEMY, at 4.15.

VICTORIA INSTITUTE, at 4.30.—Prof. T. G. Pinches: The Worship of Idols in Assyrian History in Relation to Bible References.

CAMBRIDGE PHILOSOPHICAL SOCIETY (at Cavendish Laboratory), at 4.30.—C. T. R. Wilson and Prof. G. I. Taylor: The Bursting of Soap-bubbles in a Uniform Electric Field.—Prof. E. A. Milne: Dissociative Equilibrium in an External Field of Force.—Dr. T. M. Cherry: Some Examples of Trajectories Defined by Differential Equations of a Generalised Dynamical Type.—J. Brill: Note on the Lorentz Group.—E. H. Neville: Note on the Harmonic Conic.

ROYAL SOCIETY OF EDINBURGH, at 4.30.—D. Fairweather: The Electrolysis of Salts of Alkyloxyacids.—W. West and E. B. Ludlam: The Ionisation of Iodine Vapour by Ultra-violet Light.—W. O. Kermack and W. T. H. Williamson: The Stability of Suspensions, I. The Rate of Precipitation of Kaolin Suspensions by Salts at Varying Hydrogen Ion Concentrations.—P. MacCallum and W. O. Kermack: The Influence of Gelatin on the Stability of a Colloidal Solution of Cholesterol, and on the Charge of the Particles.—W. O. Kermack and C. I. B. Voge: The Action of Salts with Multivalent Cations on Colloidal Solutions of Gold and Gum Benzoin.—A. O. Curle: Obituary Notice of the Rt. Hon. Lord Abercromby.—Dr. A. Lauder: Obituary Notice of Sir J. J. Dobbie.

BIOCHEMICAL SOCIETY (at Imperial College of Science and Technology), at 5.—E. Watchorn: The Magnesium of Human Serum.—M. E. Robinson and R. A. McCance: The Oxidation of Amino Acids by Fungus Tyrosinase.—H. W. Buston, H. N. Mukherjee, and S. B. Schryver: The Isolation of a Hydrolysis Product of the Proteins, hitherto undescribed.—H. Martin and S. B. Schryver: Some Transformations of Casein.—Dorothy Griffiths and S. B. Schryver: The Separation of the Proteins of Egg-white in an Electrical Field.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge, Kensington Gore), at 5.—A. V. Williamson: The Irrigation of the Indo-Gangetic Plain.

SOCIETY OF ENGINEERS (at 17 Victoria Street, S.W.), at 6.—Annual General Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—G. M. Clark and others: Discussion on the Pretoria Power Station.

INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—S. E. Flack: Ships' Propellers.

ROYAL SOCIETY OF ARTS, at 8.—Dr. L. C. Martin: Modern Colour Problems (III.) (Cantor Lectures).

SURVEYORS' INSTITUTION, at 8.

MEDICAL SOCIETY OF LONDON, at 8.30.—Dr. G. Graham, Prof. H. Maclean, and others: Discussion on The Present Position of the Treatment of Diabetes by Insulin.

BIOCHEMICAL SOCIETY (at Imperial College of Science).

TUESDAY, DECEMBER 9.

FARADAY SOCIETY (at Chemical Society), at 4.30.—Discussion on Base Exchange in Soils. Chairman: Sir Daniel Hall.—Dr. D. J. Hissink: Base Exchange in Soils.—Prof. N. M. Comber: The Rôle of the Electronegative Ions in the Reaction between Soils and Electrolytes.—H. J. Page and W. Williams: Studies on Base Exchange in Rothamsted Soils.—Prof. G. W. Robinson and R. Williams: Base Exchange in Relation to Soil Acidity.—S. J. Saint: The Relation between the P_H Value, the Lime Requirement, and the Thiocyanate Colour of Soils.—E. A. Fisher: Some Secondary Aspects of Base Exchange in Soils.

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section), at 4.30.—Prof. W. E. Dixon and Dr. F. H. A. Marshall: The Influence of the Ovary on Parturition.

ROYAL PHOTOGRAPHIC SOCIETY (Scientific and Technical Group), at 6.—Conference on the Standardisation of Plate Testing Methods.—The Light Source, Primary and Secondary. Spectral composition of the light source with special reference to colour sensitive plates; daylight correction filters, etc. Opening paper by J. W. T. Walsh.—The Exposure Mechanism. (*a*) Intermittent or continuous exposure; (*b*) Relative merits of wedge and sector wheel; (*c*) Other methods. Opening paper by S. O. Rawling.—Development. (*a*) Methods of development; (*b*) Effect of varying composition of the developer with the same emulsion; (*c*) Effects of temperature variation; (*d*) A standard developer. Opening paper by Dr. W. Clark.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—J. C. M. MacLagan: The Sliding Cylinder, Double-acting, Two-cycle Diesel Engine.

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Centre) (at Town Hall, Leicester) at 6.45.—T. Hall: Domestic Applications of Electricity.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (at Birmingham University), at 7.15.—D. R. Nanji and W. S. Shaw: The Rôle of Silica in Plant Growth, its Assimilation and Physiological Relation to Phosphoric Acid.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—T. Martin: The Microscope in the Study of Alloys.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Graduates' Meeting) (at Coventry).

SOCIETY OF DYERS AND COLOURISTS (Leeds Junior Branch) (at Leeds).—P. G. Marshall: The Tinctorial and Antiseptic Properties of Certain Types of Quinoline Dyestuffs.

INSTITUTION OF MECHANICAL ENGINEERS (Swansea Section) (at Swansea).

WEDNESDAY, DECEMBER 10.

ROYAL SOCIETY OF ARTS, at 5.—N. Thomson: Colombia as a Field for Development.

ROYAL SOCIETY OF MEDICINE (Otology, Laryngology, Medicine, Neurology Sections), at 5.—Dr. H. Thursfield, Sir William Milligan, Dr. W. Drought and Dr. J. G. Greenfield, W. M. Mollison, and others: Discussion on the Causes, Early Recognition, and Treatment of Non-tubercular Meningitis.

INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 7.—E. Latham: Suitable Fendering for Tidal Berths.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle-on-Tyne), at 7.—R. J. Welsh: Some Factors affecting Vacuum in Surface Condensers.

C.B.C. SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS (at Essex Hall, Essex Street, W.C.), at 8.—Miss Eleanor F. Rathbone: Family Endowment and Birth Control.

INSTITUTION OF CHEMICAL ENGINEERS (at Institution of Mechanical Engineers), at 8.—A. J. V. Underwood: The Natural Soda Deposits of East Africa.

INSTITUTION OF AUTOMOBILE ENGINEERS (North of England Centre) (Informal Meeting, at Manchester).

THURSDAY, DECEMBER 11.

INSTITUTION OF CIVIL ENGINEERS, at 6.—Capt. H. Riall Sankey: Standard of Comparison in connexion with the Thermal Efficiency of Steam Engines.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle-on-Tyne), at 7.15.

INSTITUTE OF CHEMISTRY (jointly with Society of Chemical Industry) (at 36 York Place, Edinburgh), at 7.30.—Lt.-Col. W. G. Liston: Fumigation with Hydrogen Cyanide.

INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Centre) (at University College, Dundee), at 7.30.—A. G. Norris and W. H. T. Swire: Industrial Power Supply, a Comparison of Electrical and other Methods of Driving Industrial Machinery.

INSTITUTE OF METALS (London Local Section, Joint Meeting with Institution of British Foundrymen) (at Institute of Marine Engineers), at 7.30.—F. W. Rowe: Present Problems and Developments in Engineering Bronze Foundry Practice.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—J. E. Barnard: Some Problems in Medical Microscopy.

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre) (at Trinity College, Dublin), at 7.45.

ROYAL SOCIETY OF ARTS, at 8.—Senatore G. Marconi: Radio Communications (Inaugural Address).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Chandos Street, W.), at 8.15.—Prof. W. E. Dixon, Sir Havelock Charles, Sir William Collins, and Dr. Arthur Powell: Discussion on Some Clinical and Scientific Aspects of Drug Addiction in the Tropics.

INSTITUTION OF MECHANICAL ENGINEERS (Birmingham Section) (at Birmingham).—Vice-Adml. Sir George G. Goodwin: The Trend of Development of Marine Propelling Machinery (Thomas Hawksley Lecture).

FRIDAY, DECEMBER 12.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Dr. J. Lunt: Large Line-displacements in the Spectra of Germanium and Chlorine under Different Conditions of Temperature.—Prof. E. A. Milne: The Equilibrium of the Calcium Chromosphere.—T. Allison: Squaring-on Newtonian Mirrors.—S. D. Tscherny: Occultation of B.D. −18°·6078 by Mars observed 1924, September 5, at the Astronomical Observatory, Kiew.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—Capt. A. Egerton: Numerical Values of Chemical Constants and Frequencies of the Elements.—J. H. Powell: The Sensibility of Circular Diaphragms for the Reception of Sounds in Water.—A. Campbell, with Demonstration by W. H. Lawes: A Direct-reading Frequency Meter of Long Range.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—A. Cheese: A Winter Holiday in Greece.

INSTITUTE OF METALS (Swansea Local Section) (at University College, Swansea), at 7.15.—F. Hill and others: Discussion on the Design of Furnaces for Annealing and Heat Treatment.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—H. G. Bouly: Fluid Transmission Gears.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Literary and Philosophical Society, Newcastle-on-Tyne), at 7.30.—S. B. Freeman: Fuel Oil for Marine Internal-Combustion and Steam Engines.

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8.30.—O. S. Hillman, E. Apperly, and others: Discussion on Splanchnic Analgesia with Record of Cases.

INSTITUTION OF MECHANICAL ENGINEERS (Leeds Section).—Prof. G. F. Charnock: Some Fallacies concerning Invention.

SATURDAY, DECEMBER 13.

BRITISH PSYCHOLOGICAL SOCIETY (Annual General Meeting) (at King's College), at 3.15.—Dr. C. S. Myers: A New Theory of Sensory Adaptation.—Prof. C. G. Seligman: The Psychology of the Unconscious in Relation to Anthropology.

PHYSIOLOGICAL SOCIETY (at Middlesex Hospital).

PUBLIC LECTURES.

SATURDAY, DECEMBER 6.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. N. Milligan: The Eggs of Animals.

TUESDAY, DECEMBER 9.

KING'S COLLEGE, at 5.30.—M. Kaye: F. H. Bradley—The Passage to the Absolute.

WEDNESDAY, DECEMBER 10.

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4.—Sir Robert Jones: The Problem of the Cripple Child.

UNIVERSITY COLLEGE, at 5.30.—A. Gomme: Technical and Scientific Libraries.

THURSDAY, DECEMBER 11.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4.—F. W. Twort: Modern Bacteriological Technique. (Succeeding Lectures on December 12, 15, 16, 17.)

FRIDAY, DECEMBER 12.

KING'S COLLEGE, at 5.30.—Prof. A. V. Hill: Scientific Method.

SATURDAY, DECEMBER 13.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: The Glory that was Thebes.

Science and Labour.[1]

BOTH science and labour owe a sincere debt of gratitude to the British Science Guild for its efforts, through the Conference held at Wembley at the end of last May, in establishing contact between two movements so clearly destined to change the nature of society. If nothing more has been accomplished than to establish a precedent for a periodical scrutiny of our social and industrial relations in the scientific spirit, the British Science Guild will have erected a monument to itself.

The avowed object of the conference was, to quote Lord Askwith, "to consider the lines upon which science could be directed and applied more widely and effectively to increase human health, happiness and efficiency, to reduce human toil, and to develop human personality."

Considering the scope of such an inquiry, and it embraces within its ambit the whole field of sociology, it would be amazing if any definite or concrete conclusions emerged; but while no attempt was made to collate the ideas expressed by the large number of speakers in any concise form, certain common lines of thought are easily discernible. In particular, the belief was constantly reiterated that the industrial problem must yield to scientific solution. "The scientific method," asserted Sir Thomas Holland, "is just as necessary in industrial affairs as in matters of less immediate economic importance." "It is vital," said another, "that established systems and practices should be re-examined from a scientific standpoint"; and Sir Richard Gregory: "The new conditions of industry demand a new system of industrial management." At any rate, on the part of the scientific man uncontaminated by industrial conflict, there is a real desire to approach this question in the true spirit of inquiry.

While, however, this is undoubtedly true, there is a danger against which he must be guarded. It is natural that scientific men immersed in the study of questions bearing directly or indirectly on the problem of material efficiency should regard the industrial system as centring mainly around the question of production, and it is significant that throughout the whole of this inquiry each speaker on the scientific side, almost without exception, made his contribution to this question as if it were the whole problem. Sir Hugh Bell, taking heart from his numerous supporters in this respect, was perfectly frank about it. "The one thing towards which we should struggle is . . . to aim at larger productivity," he asserts with emphasis.

1 "Science and Labour: being the Principal Addresses at the Conference on Science and Labour held in London on 30th and 31st May 1924." Edited by Thomas Lloyd Humberstone. Pp. 120. (London: Ernest Benn, Ltd., 1924.) Paper, 6s. net; cloth, 7s. 6d. net.

It is equally natural that labour, with its memory ever fresh of bitter struggles against long hours and low wages, should stress much more acutely the complementary problem of distribution of the products of its toil, remaining largely apathetic to talk of more efficient production. Mr. Cramp puts it quite bluntly when in his address he says that labour in the past has had reason to regard every labour-saving device as a wage-saving device. The labour leader will find it difficult to wax enthusiastic about science, except as a pure matter of intellectual interest, so long as scientific workers remain indifferent to the ultimate division of the wealth in the creation of which they so ardently desire to assist, ignoring the distinction between those who create wealth and those who acquire it. With all the goodwill in the world, an infinity of round-table conferences will not destroy that barrier until men of science are prepared to examine the question of distribution in the same spirit and with the same energy as they are doing in the case of production.

It is mainly for this reason that, on a study of the addresses delivered and the discussions that ensued, it is clear that, practically with one exception to which we shall presently return, the battle was not waged by the scientific men in the field of labour or by labour in the sphere of science, but by science in the realms of applied science. For that reason the employer of labour, ignoring the problem of distribution, had his full say, and science found little to urge in criticism, while labour itself was absent from the discussion. When Sir Hugh Bell ventured the above-quoted plea for more and more intensive production, there is no evidence that a single voice, scientific or labour, was raised to question the dictum or to suggest the necessity for the scientific statement of other essential conditions.

If science is to raise production to such a pitch of efficiency that everything essential to the community can be produced in sufficient quantity by a limited group of workers, it is clear that the remainder must starve unless means are adopted for placing purchasing power in their hands; that is to say, for effecting some form of distribution. The present stage of society, which utilises the wage system as a means of effecting distribution, with its million unemployed, is obviously chaotic in this respect, and from the scientific point of view utterly indefensible. It is apparent that so long as the sale of labour power by the individual worker, and thereby the receipt of a wage, is the procedure that is to be adopted for effecting distribution, so long will labour as a whole remain apathetic—if not antipathetic—to scientific schemes of production that may decrease his opportunities for such sale.

Science must face this question squarely. It is contended by Lord Ashfield, in his intensely interesting address describing the historical and scientific development of the London omnibus service, that the introduction of scientific improvements into the system, while it may have led temporarily to the employment of fewer workers in the industry, ultimately swelled their numbers. This provision of employment, he asserts, was therefore something which redounded to the benefit of labour. Apart from the fact that the sudden cessation of employment among the men initially displaced laid the brunt of an unsound distributive system immediately upon a group scarcely fitted to withstand it, it is not clear that anything more was finally achieved in this respect than that men were merely transferred to more productive employment; and, as we have already indicated, mere productiveness is not sufficient in itself. If Lord Ashfield's contention were valid, one would anticipate that since the industrial revolution the percentage of unemployed would have decreased continuously. We doubt if this would be borne out by the facts.

Even on the productive side there are questions which, merely from lack of examination, we are prone to prejudge. We have become accustomed to the constant repetition of the phrase "speeding up," and in the mind of labour it is associated with much of the valuable work done on industrial psychology. But suppose the individual workman be urged to work at his maximum capacity, will his output be increased 20 per cent.? Now suppose the employer be urged to introduce the maximum of science and scientific method into his factory, by how much will the output ultimately be increased? We would suggest that the history of the cotton industry, where the output since the age of scientific invention has increased something like fifty-fold, is illuminating. How futile when viewed in this light does the grudging attitude of many captains of industry to science and labour become. How inefficient also are the means adopted for bringing the perfected article to the consumer is apparent when we recollect that for most proprietary articles, out of every three produced approximately two are absorbed in providing the third with what the economists would term "utility of place."

The single field upon which all groups appear to have met was that set for "The Place of Science in Government," and here a discussion arose of intense moment to all scientific workers whose interests extend beyond the mere confines of their laboratory. The gauntlet was thrown by Mr. Sidney Webb, who, in the course of his address on "Knowledge and Control," asserted that concentration on scientific work frequently gave rise to a narrowness of outlook and that this inevitably implied that the scientific expert, while he had a place, and a distinct place, would not find it as an adminis-

ative or as a governmental head even, it is presumed, hen the subject of administration was scientific. The nction of the politician, he contended, was to interpret he will of the people, and on the expert guidance fforded him by the man of science, to express this will s a detailed practical policy. On this challenge there ere, of course, not lacking protagonists with a memory f past or present lay control of their scientific work to ttack various aspects of this point of view. If only or this part of the discussion, the report of the Conerence is well worth study.

It is a strange doctrine that because a cramped utlook is sometimes associated with extreme concenration on scientific work—and we venture to suggest hat this is not confined to scientific work—there must e a definite limitation of the administrative scope ven of those who have avoided this narrowness. This ictum can have any validity at all only if it can be emonstrated that a true scientific training is inferior in eneral as an educational influence to that of any other, nd that the scientific method is of little moment in overnment and administration. Unfortunately, any ttempt to discuss this question with those who themelves have escaped a scientific training immediately eveals a fundamental confusion between what is neant by the scientific method and what is a mere umble of chemical or physical facts and propositions in Euclid. To some extent our school and university eaching, where it ignores the broad underlying rinciples of scientific knowledge and inquiry, and harps too insistently on the mere technical facts, is artly to blame for this false conception of the true educational value of science. But in any event Mr. Webb's attitude on this matter would appear to run directly counter to the spirit of the whole Conference, that the scientific method is essential to the solution of industrial problems.

If we are to re-examine old-established systems and practices from the scientific point of view, we must join issue with Mr. Webb at even an earlier point than this. He is satisfied apparently that, all things considered, we are happy in the possession of a democratic system in which the considered will of the electorate as interpreted by the politician is put into effect by him with the guidance of the expert where the politician deems it necessary. Can it be contended in all seriousness that the present conditions under which electoral decisions are registered are even an approximation to the type of democracy Mr. Webb has in mind, or from the point of view of the scientific man, even a remote approach to an efficient instrument for deciding matters of fundamental communal importance? If it is desirable that even on matters of minor scientific consequence an unfettered unbiassed judgment should be exercised, and that at moments of such decision external distractions and emotional factors should be absent, how much more important is it that on matters of national consequence, involving the welfare of millions for years, at least similar conditions should apply? Is it necessary to point out that, with a press for which liberty is licence and prejudged issues are truth, it is impossible at a general election to attain the requisite calm for the exercise of a considered judgment by a democracy ill-equipped to rise above the passionate clamour of parties? It may be necessary to tolerate this at present as the only instrument to hand, but let us not at least be blind to its inherent weaknesses, so that in establishing an administrative and governmental machine upon it, none of the more grotesque results of democracy as practised at present should be exaggerated.

We have not done justice to this record of a notable occasion. It abounds in material of fundamental importance to the scientific and labour movements, and we can only hope that the British Science Guild, taking heart again from its experience this year, will place one more stone next year upon this worthy structure.

H. LEVY.

Activity of Vesuvius, 1903-1921.

The Vesuvius Eruption of 1906: Study of a Volcanic Cycle. By Frank A. Perret. (Publication 339.) Pp. 151 + 24 plates. (Washington: Carnegie Institution, 1924.) 4 dollars.

THIS valuable monograph gives the results of the author's investigations on the state of Vesuvius from the end of 1903 to 1921, and more especially his observations on the mountain during the height of the eruption of 1906, which culminated in the stupendous outbreak on the night of April 7-8. The volume is divided into five sections. The first deals with the events of 1904–5, the second with the eruption period in April 1906, the third with the post-eruptive period of repose, and the fourth with the seven following years of present activity. The fifth contains descriptions of apparatus invented or modified by the author for better determinations of temperature and the perception of subterranean sounds, etc., and also of diagrams for recording the phenomena concisely. A postscript by Mr. H. S. Washington deals with the analyses of lavas which have flown from the crater at different periods and gives some useful notes. There are 24 full-page plates and 98 text-figures, which are mainly reproductions of excellent photographs made by the author.

The volcano's activity began at the end of 1903, and during the next two years good opportunities of

investigating the phenomena were afforded. The cone was steadily rising in height until in May 1905 its top was nearly 4400 feet above sea-level. The vent was small, and the lava reached nearly, if not quite, to the top, whence it was ejected several hundreds of feet from time to time. Such portions as fell on the outside were still hot and plastic, and helped to consolidate the cone. On May 27, the author saw a white cloud shoot from the side of the cone at a short distance below the top, and this was quickly followed by a flow of lava. Soon there were three streams flowing from fractures at points near one another, but at different levels below the top. These relieved the extreme pressure on the cone, and the great outbreak was postponed.

As depicted by the author, the mountain differed widely from its state in 1902, when the crater was wide and deep with a small vent near its middle, from which stones were occasionally thrown up a few feet. During the summer of 1905 the author had an experience of the way in which the cone was being corroded by the hot fumes and lava within. Standing with some students on the side of the cone, they noticed that the ground began to get hot, and it soon became unbearable. Soon after they had moved off, a patch about 2 yards across became red-hot, fused, and gave rise to a small lava flow.

The main eruptive period may be said to have begun in February 1906, when there was an abundant flow of lava with loud explosions, and clouds of ash were thrown out. This state continued with some abatement until the equinox, when jets of lava were thrown out, some horizontally, so that the cone was filled to the brim. The final stage began at midnight, April 4-5, when lava poured out of a new opening on the south side at a height of 2600 feet above sea-level. On April 6 the lowest vent opened about 5 furlongs east of the last, and about 600 feet lower; from this and an adjoining vent poured out the mass of lava which reached and blocked the railway at Bosco Tre Case. The eruption culminated about 3.30 A.M. on April 8, with a great outburst of hot ash, lava, and debris, some of which caused the serious catastrophes at Ottajano and S. Giuseppe, where they were deposited to a depth of nearly 3 feet. The next extraordinary event was the great uprush of gas about 4 A.M. This is represented by a drawing and not a photograph; it is made to ascend to a height of about 8 miles, and marked, according to the author, the *intermediate gas phase*, the gas coming from great depths and being comparatively free from ash. It was followed on April 8 and subsequent days by the dark-ash phase, the columns and billows of which probably attained a height of 3 miles above the crater. The mountain and country round were covered with a great depth of ash, which on the steep slopes gave rise to dangerous hot avalanches, and at a later period to mud avalanches, from which the towns have to be protected by strong walls. The loss of material caused two subsidences near the top of the mountain, and reduced its heights by 350 feet on the N.W. side and 700 feet on the opposite side, the crater becoming a wide-throated funnel some 770 yards across at the top and sloping down at an angle of nearly 45°. Estimates of the quantities thrown and poured out differ widely, but the flow of lava on the southern flank covers about 3,000,000 square metres, and its volume is about 10,500,000 cubic metres.

The author discusses at some length the possibility of a luni-solar influence on eruptions, but leaves the question open. Now the difference of attraction on so small a volume must be inappreciable in its effect on so viscous a substance as liquid lava, and independently of this, the active stages in February and April preceded the full moon by seven and five days respectively. Palmieri, in his account of the 1872 eruption, seems to favour the view, for he says: "in the month of March, with the full moon, the cone opened"; and later, "on the 23rd April (another full moon) . . . splendid lavas descended." Earlier, however, he states that on November 3 and 4 "copious and splendid lava streams coursed down," the moon being full on October 28 and November 27.

The seismic disturbances and subterranean noises were very considerable and were powerfully felt at Pompeii, and probably at greater distances. With the friction of the matter ejected great electrical energy was developed, and manifested itself in short lightning flashes over a considerable portion of the sky.

The narrative portion of the book is extremely interesting, and the discussion of the phenomena is full of suggestion and shows good discrimination.

W. J. L.

Lime and Magnesia.

Lime and Magnesia: the Chemistry, Manufacture, and Uses of the Oxides, Hydroxides, and Carbonates of Calcium and Magnesium. By N. V. S. Knibbs. Pp. 306. (London: Ernest Benn, Ltd., 1924.) 30*s.* net.

THE work under notice is the first book or collection of classified information on the manufacture and properties of lime and magnesia which makes any pretence to be a comprehensive survey of the situation. As such, the author is to be complimented on the result of what must have been to him a long and painstaking piece of work. The volume is divided into three parts: Part I., occurrence and classification of limestone and magnesite, and the chemical and physical properties of

ne and magnesia; Part II., quarrying and manufacture lime and magnesia products, and Part III., their use commerce and industry. Of the three, the first may be said to be satisfactory, the second to be less so, and he third to be a rough attempt to outline the very aried uses to which lime and magnesia products are ut. It is questionable whether it would not have been dvisable to publish the three parts in separate volumes, nd make those on manufacture and usage very much ore exhaustive. This would, it is true, be even more borious, but the ultimate value of the work would have en greatly enhanced. Moreover, had the author llowed this course, he need have had no fear of being restalled in the field.

In dealing with each section separately, the following oints seem to be of interest. The classification of arious limestones is good, and an admirable feature of he book is the bibliography and references at the end each chapter. There is a fairly ample discussion on he work of Johnston on the thermal dissociation of mestone. It seems to be the only really first-class esearch which has been done in this field. The method etailed for measurement of the apparent density of me seems somewhat crude, and it is unfortunate that o better method has been described for measuring this roperty, from which most of the other physical properties of the sample can be determined. The remainder fairly exhaustive, but it would be interesting had the uthor expressed his own opinion on the relative merits f some of the diverse facts and theories which he has ollected. On the whole, this section is very capable, hough it seems a matter of conjecture whether the nglish lime burner, practical man as he loves to style imself, will take much account of it.

Of the remainder of the book there is not so much o be said. Part II. contains a long harangue on the ncient kilns which are so much in favour in Great ritain. There seems little to recommend them, save hat they have been in use for generations. Rotary ilns are scarcely mentioned, though they are a standard art of the equipment of most American lime works. ittle as one likes to admit it, the English lime-burning ndustry is a very poor second to American practice and utput, even though we are far ahead of them in respect f our quarry resources. Hydration is far too scantily reated, though, of course, the English output is quite nsignificant and the product high in price. Quarrying s very lightly passed over, and only a very general urvey of accepted methods is undertaken.

The section on the uses of lime and magnesia products s as good as it can be in the space devoted to the ubject, which is very small compared with its importance.

As a whole, the book appears to be a fairly comprehensive survey of the lime and limestone industry, but not so much so in the case of magnesia. As an incentive to research it would seem invaluable. The author has, so to speak, broken the ice, and accomplished his primary object successfully. It would have been more satisfactory, however, had he been far more critical in his handling of the subject, the lime industry being somewhat in need of it. F. A. FREETH.

Antarctic Meteorology.

British Antarctic Expedition, 1910–1913. Meteorology. Vol. 3: Tables. By Dr. G. C. Simpson. (Published for the Committee of the Captain Scott Antarctic Fund.) Pp. xi+835. (London: Harrison and Sons, Ltd., 1923.) 60*s*.

THE physical researches of the *Terra Nova* expedition are now complete in 13 volumes, including one of miscellaneous data still in the press. Dr. Simpson published the first two volumes of the meteorology of Scott's last expedition in 1919, the first containing the discussion of the data and setting forth his conclusions, the second reproducing the weather maps and traces of recording instruments. Volume 3 now supplies the data on which the earlier volumes were based, including hourly readings of all the instruments at the main base, Cape Evans, and the meteorological logs kept at the various subsidiary bases and on journeys. It is a massive monument of the rare devotion with which Dr. Simpson and his many helpers worked in circumstances of the greatest difficulty, and the survivors of them are to be congratulated on its completion. Dr. Simpson must be thanked also for not delaying by five years the publication of his epoch-making general conclusions, to wait for the end of the labour of seeing this huge volume through the press.

In the preface it is pointed out how greatly the value of the meteorological work was enhanced by the concurrence of the Norwegian expedition in the journeys to the South Pole, a subsidiary part of Scott's expedition although the main aim of Amundsen's. Through the unexpected advent of the *Fram*, Scott's eastern party was diverted northward to Cape Adare while the meteorological work at Framheim gave a third series of highly accurate synchronous observations for very nearly a whole year. As Cape Adare is 400 miles north and Framheim 400 miles east of Cape Evans, the three stations enabled synoptic maps to be constructed of the whole Ross Sea area. It is to be regretted that the meteorological data of the Australian Antarctic expedition, which was simultaneous with the second year of Scott's expedition, could not have been dealt with also in these volumes.

In addition to the records at the fixed stations (those at Framheim being given in the British units) the volume includes the meteorological logs of all the sledge journeys and of the voyages of the *Terra Nova* from and to New Zealand. The utmost care was taken in all these observations to define the time-standard used and the true direction in the case of wind and of cloud movements; both these items present difficulties peculiar to very high latitudes, and carelessness in regard to them has deprived some past records (made otherwise with the greatest care) of all their value.

This volume has its sole use as a work of reference, and it ought to prove invaluable when the time comes for a critical discussion of Antarctic meteorology in the light of all records, including those of expeditions the detailed work of which is still unpublished.

Vol. 1 of the meteorology, which was printed in India, is provided with a running title greatly facilitating reference and permitting of the workmanlike numbering of the pages in the outer upper corner; Vol. 3, printed in London, conforms in this respect not to Vol. 1 of the meteorology set, but to the volumes dealing with the other departments of science, which unfortunately have no page-headings. This is neutralised in the case of tables printed across the breadth of the page and only causes delay in referring to the tables which are printed across the length of the page. A more serious defect is that the volume under notice (like most of the others) is numbered awkwardly in the middle of the page at the bottom, so that it is necessary to make a complete opening in order to see the number, instead of merely flicking the top outer corner. H. R. M.

Our Bookshelf.

A Survey of the Fauna of Iraq: Mammals, Birds, Reptiles, etc. Made by Members of the Mesopotamia Expeditionary Force "D," 1915–1919. Pp. xx+404+20 plates. (Bombay: Bombay Natural History Society; Basra and Baghdad: *The Times* Printing and Publishing Co., Ltd.; London: Dulau and Co., Ltd., n.d.) 10*s*. net.

THE study of the survey of the fauna of Iraq is a convincing proof that the interest in systematic zoology is still well maintained in Great Britain. It is really very remarkable that notwithstanding the hardships and discomforts of the campaign in Mesopotamia, no less than eighty-four of the members of the British Expeditionary Force "D" were keen enough to collect and observe the animals of the country through which they passed or in which they fought.

The papers which constitute this volume were first published in the Journal of the Natural History Society of Bombay, and are now reprinted and published with the authority of the Iraq Government. They deal with the mammalia, birds, reptiles, insects, myriapoda, and crustacea that were collected during the year 1915–1919. The only large groups of terrestrial o freshwater animals that are not included in the volum are the mollusca, arachnida, and fishes. It would b interesting to know if material belonging to these group were also collected and will be described in later papers

With a book of such great value and varied interes it is impossible, in a short notice, to convey a jus appreciation of its manifold merits. To some natural ists the papers on the birds by Buxton and Ticehurs will appeal most strongly. Dr. Buxton's notes on th avi-fauna of Northern and Western Persia are par ticularly interesting and well written, giving a ver vivid impression of the birds that may be seen in journey through the country by any traveller wh possesses the keen sight and knowledge of a trained an gifted ornithologist. Dr. Ticehurst's contribution o the birds of Mesopotamia, with its more detaile account of the species, including most interesting note on their habits, nests, and eggs, is rendered mor fascinating by some remarkably good photographs o the nesting places of many of the birds.

To others the more attractive papers will be those o Col. Piele on the butterflies. Here, again, the autho is not content to give a simple list of species in th collection, but adds many valuable notes on variatio and habits. The naturalist who is not a professe entomologist will read with much interest, for example the three pages of notes on the well-known swallow-ta *Papilio machaon*.

In selecting these two series of papers for specia mention, we have no wish to underrate the value an importance of the others in this volume. Every pape has been written by a well-known authority in hi group, and, so far as we can judge, it has been treate with the greatest possible accuracy and care.

We can only congratulate the many authors an collectors on the production of such a remarkable an valuable work.

Leaves from the Golden Bough. Culled by Lady Frazer Pp. xii+249+16 plates. (London: Macmillan an Co., Ltd., 1924.) 10*s*. 6*d*. net.

IT was a happy idea of Lady Frazer's to transform by a few magical touches the learned treatise o anthropology into a fascinating book of stories fo children. It is remarkable how readily young folk will respond to good literature, to true talent and t real wisdom. Any one who wishes can convince himsel by experiment of this fact by observing how children of four years onwards will listen with delight t properly chosen passages from Homer, Shakespeare and Cervantes. Frazer's "Golden Bough" contains the most universal and catholic collection of stories customs, and practices, and these in illustration o some of the most dramatic and mysterious aspects o human nature; and it is told with a unique charm and power by the illustrious author. From thi masterpiece of literature and science, Lady Fraze has judiciously selected a number of appropriat incidents which will impress once for all on the youn mind the most important facts of anthropology. Th child will be keenly interested to hear what the mistleto bough really means in the Christmas festivities an what it meant to our ancestors. He will follow eagerly

he strange adventures of ancient heroes of Greece, of he semi-animal gods of Egypt, the sagas of Teutons nd the folk-tales from five continents and numberless slands.

The wide range, the extreme variety of local colour, he flavour of the distant, of the primeval and of the xotic, so wonderfully preserved by Sir James Frazer, vill be a delight to every young reader who, as we now, is so susceptible to the lure of the remote and antastic. What makes this book unique, however, s not its harvest of folk-lore, but the accounts of elief and custom which form the bulk of the selected assages. The child finds himself in real intimacy with Red Indians and their hunting expeditions and lodge estivals, with South Sea Islanders in their fishing and loral dances, with the hairy Ainu of Japan worshipping he bear. Moving through the wonderful landscapes of the world, tasting of genuine savage life, sharing he beliefs of all ages and all races, the child will eceive at the same time an excellent foundation for is future humanism. The pleasing illustrations by Mr. H. M. Brock add another touch of life to these ntrancing pages.

The Mortality of Annuitants, 1900–1920: Investigation and Tables. By W. Palin Elderton and H. J. P. Oakley. (Published on behalf of the Institute of Actuaries and the Faculty of Actuaries in Scotland.) Pp. iv+207. (London: C. and E. Layton, 1924.) 42*s.* net.

MESSRS. Elderton and Oakley have given an account of their investigation into the mortality of annuitants as ascertained from data supplied by the leading Life Offices in Great Britain. The investigation covers the period 1900–1920, whereas the tables previously in use related to the years 1863–1893. A striking decrease is shown in the rates of mortality of both men and women, and this fall in the rate of mortality has led the authors to propose a method of forecasting the mortality likely to prevail in the future. For this purpose they assume that the rate of mortality applicable to a given age-group can be expressed in the form $A+Bc^x$, where x is the calendar year in which the annuity is purchased.

The constant A for any age-group thus represents the figure to which the rate of mortality will ultimately fall. This is taken arbitrarily at 63 per cent. of the 1900–1920 rate, and the required value of the forecasted rate of mortality is then found by logarithmic exterpolation from the values given by the 1863–1893, and the 1900–1920 data, the assumed year of purchase being calculated for each age-group from the average duration of contracts in force. For example, in the age-group 80-84, where the average duration is 16 years, the forecasted rate of mortality for those ages, in respect of an annuity purchased in the year 1925, is that applicable to the year 1941, and this average rate is apparently taken whether the annuity be purchased at the age of 40 or at 80. In the result it would seem that the method must tend to overstate somewhat the projected annuity values at the older ages.

The book concludes with the usual adjusted life tables and monetary tables for single and joint lives. It will be of the greatest value to all who require an up-to-date mortality experience of a sheltered class.

A Treatise on Light. By Dr. R. A. Houstoun. New edition. Pp. xi+486+3 plates. (London: Longmans, Green and Co., 1924.) 12*s.* 6*d.* net.

DR. HOUSTOUN'S text-book, which was first published in 1915, has achieved a wide and well-deserved popularity, and the present edition is supplemented by a short additional chapter on "Recent Advances." Frankly, it is a disappointing chapter. First, the interferometric determination of the angular diameters of stars is briefly treated from an elementary point of view, then half a page is rather unnecessarily expended on descriptions of half-watt and neon lamps. There follows an account of the verification of Einstein's predicted gravitational deflexion of light, but no mention is made of the application of the theory in connexion with the fine structure of spectral lines. The quantum theory is next discussed. This is admittedly a difficult matter to expound in the space of a page, but even so Dr. Houstoun might have given us a more inspiring survey of this fascinating subject. Even the most impenitent classicist should be capable of appreciating the remarkable achievements of the quantum theory, and one cannot help feeling that the bald and unilluminating account here presented is unworthy of the rest of the book. Further, in the final section, which is entitled "Moseley's Work on X-ray Spectra," a statement occurs which can scarcely pass unchallenged. It is that "the examination of spectra in the visible region and near ultra-violet, while affording many interesting results, has not been fruitful as regards the structure of the atom or the mechanism of the production of spectra itself." After this, it is not so surprising to find no mention of Bohr anywhere.

It is greatly to be hoped that in a future edition a more adequate treatment of these matters will be attempted. At the same time, Dr. Houstoun should take the opportunity of rewriting the account of spectral series on pp. 271-275, which is now completely out-of-date.

Cancer: its Causation, Prevention and Cure. By Dr. John Harger. Pp. xv+139. (Liverpool: C. Tinling and Co., Ltd., 1924.) 5*s.*

UNTIL the cause of cancer is discovered, it will remain common ground for ill-informed persons to express their views. The most recent amateur recruit to the cancer problem is Dr. John Harger—apparently a chemist—who considers that as such he has had a "precious legacy," handed to him by Pasteur, namely, "the *right* to interfere in matters of logic, especially when applied to subjects treating of disease." In spite of the statement (p. 132) that "This legacy we must guard and use with discretion, lest it be besmirched by our blundering," his book might be described as a compendium of erroneous and useless elementary anatomical, physiological, and pathological data. In an amusing glossary we find "Atrium (the open court).—The auricular parts of the heart." "Cervix" is said to be the "neck of an organ, etc." "Fibrin" is defined as the "protein in the fibrous parts of the body and in the membranes, cell walls, etc." The suprarenal capsule is a "small attachment to and above each kidney." We are also told that;

in cancer patients, "the red blood corpuscles possess nuclei, which is not the case in normal health."

It is difficult to make out the author's real viewpoint on cancer, but apparently it has something to do with diet. He extols the virtues of Dr. R. Bell, Mr. Forbes Ross, and Dr. John Shaw; and accepts in part their very diverse theories. Incidentally, he is critical of Mr. Ellis Barker and surgeons.

Ore Dressing: Principles and Practice. By Prof. Theodore Simons. Pp. xviii + 292. (London: McGraw-Hill Publishing Co., Ltd., 1924.) 17*s.* 6*d.* net.

TEXT-BOOKS of ore dressing are frequently little more than extracts from makers' catalogues. The volume by Prof. Simons is of a different character. It gives the usual descriptions of plant, but enters more fully into the principles of the processes of separation and deals quantitatively with the theoretical and practical limits of concentration, and with the theory of grinding. It is readable and should be found exceedingly useful by metallurgists in general. The subject of flotation is rather briefly treated, and the theory, of such remarkable scientific interest, is only alluded to, the reason being given that several important works devoted entirely to flotation have been published recently. Magnetic separation might with advantage have been treated more fully. It is extremely important, and the apparatus figured and described is only one of many efficient types. It is unfortunate that this subject should not have been treated with the same fulness as the mechanical processes, as the applications of magnetic separation are continually increasing. Should a further edition of the book be required, several sections might be expanded with advantage without altering the general character of the work or injuring its readable quality.

C. H. D.

The Structure of Matter. By Dr. J. A. Cranston. (Manuals of Pure and Applied Chemistry.) Pp. xvi + 196. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1924.) 12*s.* 6*d.* net.

MOST of the books dealing with the structure of matter have been written rather for the physicist than for the chemist, and there was room for a simple yet sufficiently detailed account of the subject treated from the chemical point of view. Dr. Cranston would seem to have filled this gap very successfully. He gives a preliminary account of the determination of the mass and charge of the electron, of radioactivity, atomic numbers, isotopes, and crystal structure, in all cases giving adequate descriptions of the experimental methods, and then proceeds to discuss the various atom models, and the valency theory of Langmuir. The space devoted to the Bohr atom may seem inadequate, but it must be confessed that its chemical applications are still vague and that Langmuir's ideas, although probably less physically sound, seem to afford greater assistance in this field. This part of the subject is well explained. The book is attractively illustrated, and references for further reading are given. Both teachers and students of chemistry will welcome Dr. Cranston's quietly written book as the best for their purpose which has yet appeared.

Practical Calculus for Home Study. By Prof. C. I. Palmer. Pp. xx + 443. (London: McGraw-Hill Publishing Co., Ltd., 1924.) 15*s.* net.

THIS book is professedly written for the practical man who, having already a considerable knowledge of subjects that lend themselves to mathematical formulation and discussion, has yet a very indifferent mathematical equipment. For success in its purpose such a book must satisfy two requirements. It must, in the first place, continuously correlate each complete step in the analysis with concrete problems of practical significance, so that the reader may feel at no stage that he has lost touch with his solid ground. In the second place, the development of the subject must fit into a general scheme in order that the existence of wider fields of inquiry may not be obscured. The present volume, with effectively the same range as most elementary text-books on calculus, fulfils the first of these requirements with a considerable measure of success, practical examples being taken from almost all branches of physics and engineering, besides those of a purely mathematical nature. To satisfy the second requirement is much more difficult in the circumstances, and the author has at any rate made it apparent that he is alive to its importance.

(1) *Technique of Tissue Culture "in Vitro."* By T. S. P. Strangeways. Pp. xii + 80. (Cambridge: W. Heffer and Sons, Ltd., 1924.) 7*s.* 6*d.* net.

(2) *Tissue Culture in Relation to Growth and Differentiation.* By T. S. P. Strangeways. Pp. x + 50 + 4 plates. (Cambridge: W. Heffer and Sons, Ltd., 1924.) 5*s.* net.

(1) FOR some time the author has been known as a most successful cultivator of living tissues *in vitro*. His small book describes in the minutest details his technique, and is a notable contribution to the subject; it is invaluable to those who wish to follow this promising line of work.

(2) It is not quite easy to understand why this booklet was separated as a fragment from the author's other work described above, and why its dimensions should be different. It deals with observations of tissue cultures and their possible significance in relation to growth and differentiation. The author's meaning is not always apparent, and in some places the writing is involved, but the book must be ranked as an important if short contribution to a fundamental subject of biology.

Problems of Belief. By Dr. F. C. S. Schiller. (Library of Philosophy and Religion.) Pp. 194. (London: Hodder and Stoughton, Ltd., n.d.) 3*s.* 6*d.* net.

DR. SCHILLER'S little book is a serious contribution to a large philosophical problem. The author's irrepressible humour enlivens the subject and prevents it being for a moment dull. Some years ago, Dr. Schiller sent out a *questionnaire* with the view of discovering how far the desire for a future life is general, and how far, in those who acknowledge it, it is modified by the conditions they attach to it. Many of the answers were surprising and not a few entertaining. An appendix inserted in the middle of the book gives an account of this interesting experiment.

Letters to the Editor.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

The Influence of the Degree of Instability on the Phenomena of Round Liquid Columns.[1]

THE instability of round liquid jets was noticed and described by Savart,[2] Magnus,[3] Plateau,[4] and others. The criterion of instability was given by Plateau as

$$\frac{\lambda}{d} > \pi, \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where λ is the "wave-length," measured along a portion of the jet where the diameter is d. Or, in words, the jet is unstable when the wave-length is greater than the circumference.

This criterion depends only upon the tension of the surface and applies to any round column of fluid bounded by such a surface. Thus Boys[5] demonstrated this instability by a purely static experiment, in which a soap film was stretched between the circumferences of two equal and coaxial rings, and these were drawn apart along their common axis. The film collapsed when the distance between the rings was equal to the circumference of either.

The late Lord Rayleigh recognised that the question whether or not an actual jet breaks up in the allotted time, depends also on the *time rate* of its collapse, and thus on physical and geometrical properties of the jet other than its surface tension. This fact seems, however, to have been overlooked by many others. It seems worth while, therefore, to emphasise its significance by a few illustrations of phenomena that depend on this consideration for their explanation. The purpose of the present communication is to furnish these illustrations and to put the factors on which this rate depends, deduced by Rayleigh, into more convenient form for study.

In Rayleigh's treatment[6] external forces were neglected, as was any uniform forward motion common to all parts of the jet. The jet was thus treated as an infinitely long cylinder of liquid initially in equilibrium under the action of the tension of its envelope. The disturbances by which this equilibrium was upset were assumed to act independently of one another. The change in potential energy, caused by a given disturbance, was computed from geometrical considerations, while the kinetic energy, due to the motion of the liquid caused by the disturbance, was evaluated on the assumption that a velocity potential existed. Application of Lagrange's generalised equations of motion then gave the differential equation stating the time rate of variation of α, the "amplitude" of the disturbance. The solution of the equation was found to be

$$\alpha = \alpha_0 e^{qt}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where e is the Naperian base,

and

$$q^2 = \frac{8T}{\rho} \frac{[F(z)]^2}{d^3}, \quad . \quad . \quad . \quad . \quad . \quad (3)$$

In (3) T, ρ, d denote surface tension, density, and diameter, respectively;

and

$$[F(z)]^2 \equiv \frac{z}{J_0(iz)} \cdot \frac{\partial}{\partial z} J_0(iz) \cdot (1 - z^2) \quad . \quad . \quad (4)$$

Here

$$z \equiv \pi d/\lambda \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

and

$$J_0(iz) = 1 + \left(\frac{z}{2}\right)^2 + \frac{1}{(2!)^2}\left(\frac{z}{2}\right)^4 + \frac{1}{(3!)^2}\left(\frac{z}{2}\right)^6 + \ldots \text{ etc.} \quad (6)$$

Aside from the factor $(1 - z^2)$, the rest of the second member of (4) is real and positive; hence q is real if $\lambda > \pi d$ and imaginary if $\lambda < \pi d$. Imaginary values of q correspond to stable oscillations of cross section, but when $\lambda > \pi d$ so that q is real, the amplitude α increases continually,[7] until, when $\alpha = d/2$ the jet breaks up into drops, the rapidity of this collapse increasing with q.

FIG. 1.—The collapse of a round falling liquid jet.

Now it is seen from (3) that the value of q, for a given liquid, is determined by two factors: (*a*) it increases as d decreases; (*b*) it increases as $F(z)$ increases. A necessary accompaniment to the study of the phenomena of any jet is, therefore, a study of these two factors.

As to (*a*), the increase in q, being 50 per cent. greater than the decrease in d which causes it, can be readily computed once the change in d is known. Unfortunately this latter is often difficult to determine in the case of a jet; but it is often possible to get an approximate idea of this change, and even this should be considered in any attempted explanation of given jet phenomena.

Fig. 1 is a typical spark photograph of a round jet of water, falling vertically. The orifice chamber was influenced by an electrically driven tuning-fork, the energy of which was propagated in a direction parallel to the axis of the jet. The fork frequency (n), head causing *efflux* (h), and *jet* diameter (d) were mutually adjusted to satisfy the inequality

$$\frac{\sqrt{2gh}}{n} > \pi d \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Therefore, since the vibrations served merely to regularise the disintegration process, and since this photograph is typical of the form of the jet at any instant, it may be taken as picturing, *at intervals of* λ, the progress of a disintegrating disturbance impressed at the root of the jet.

We note the formation of an indentation in the surface, due to the vibration. This soon grows into a ligament separating the swellings of the main jet. This ligament, having a λ/d ratio greater than π, is unstable, and collapses in the manner indicated above. But its degree of instability is very high, on account of its small diameter. Further, since the ligament is getting progressively finer, its degree of instability is at the same time increasing. q is, therefore, an *implicit increasing* function of t. The ligament thus collapses in a shorter time than would be required for α to equal the jet radius if q were determined only by the initial dimensions of the jet, and a small drop is formed between each pair of larger drops.

Now Rayleigh, in discussing[8] the cause of the reflections of the small drops between the large drops, which is made evident by stroboscopic examination,

[7] q can only be positive if real, since such displacements cause a decrease of surface.
[8] Rayleigh, Enc. Brit., 11th Ed., 5, 271, Art. on "Capillary Action."

and by the fact that, in a horizontal jet, the small drops are thrown out of the vertical plane containing the main jet, says that this is caused by the ligament being in a more advanced stage of its development at its front end than at its rear, thus causing an initial collision between each small drop and the large drop following. Considering the facts just mentioned, this explanation seems quite plausible.

Another related phenomenon is that recorded by Ollivier.[9] He observed that, when a drop of water fell upon a smoked surface, a fine ligament was formed at rebound, causing a small drop to be projected in a direction normal to the surface. This phenomenon was ascribed by Ollivier to the fact that the length of this ligament was greater than its circumference, and it was therefore unstable. It is not evident, however, until we consider Rayleigh's work on the variation of the rate of collapse with the diameter of the liquid column, why this ligament collapsed before the liquid at its end could be drawn back into the main drop.

We must now consider the variation of q with λ/d. From (4) Rayleigh computed enough values of $F(z)$ to show the existence of a maximum, of value 0·343, at $\lambda/d = 4{\cdot}5$ (approximately). These computations have been slightly extended by the writer, and the results are shown in convenient graphical form in Fig. 2, where $F(z)$ is plotted as a function of λ/d. It should be remembered that q, which measures the degree of instability, is directly proportional to $F(z)$ for a given liquid and jet diameter.

$F(z)$ is zero for $\lambda/d \leqq \pi$. After this instability point is passed, the value of $F(z)$ increases very abruptly. This accounts for the possibility of quantitatively recognising the instability point, as in an experiment described by the writer.[10] In this connexion it should be noted that since the experimental recognition of the instability point depends on the particular form of the function $F(z)$, the practical application of Plateau's criterion is due to Rayleigh's work.

A somewhat similar experiment has been described by Lord Rayleigh.[11] He observed the following: When the orifice from which a rising jet issued was influenced by a tuning-fork of proper frequency, the jet broke on its upward path. As the vibrations of the fork died down, and the initial amplitude a_0 consequently decreased, the point at which the jet broke rose, but could not be made to pass a certain point, which Rayleigh assumed to be the instability point. Unfortunately, he records no quantitative data, so that one cannot say *from these observations* whether the (length/diameter) ratio for this point was π or some slightly greater number.

The maximum of the curve is not at all sharp. Now in some of Savart's experiments the fall of the drops formed from a jet influenced the orifice chamber, and thus determined the further rupture of the jet. Under such conditions, after the lapse of a short time, the jet collapses in a regular manner, quite similar to Fig. 1. But such a jet should pick out a value of λ/d corresponding to the maximum of Fig. 2. Now Plateau, reasoning from Savart's results, found 4·38 as the λ/d ratio for this point. Consulting Fig. 2, it is seen that the ordinate value at this point is insignificantly different from that at $\lambda/d = 4{\cdot}5$. Hence it is evident that this is a contradiction neither of the accuracy of Savart's experimental work nor of Rayleigh's theoretical work.

For values of λ/d greater than that corresponding to the maximum of $F(z)$ the curve slopes down very gently. Now it is an experimental fact that gravity has but slight effect on the phenomena in a falling jet, when λ/d is initially greater than 4·5. In such a jet, gravity causes an increase in the λ/d ratio of a ligament and a corresponding decrease in d. These have opposing effects on q. The increase in q due to decrease in d slightly exceeds the decrease in q due to increase in λ/d ratio, and the jet breaks sooner than it would according to Rayleigh's treatment, which neglects gravity.

The above quotations could be multiplied almost indefinitely, as will be evident to those familiar with the literature on the subject. It is thought that they furnish the illustrations desired.

It should be noted that we have here one example of a useful principle, which, while quite obvious, does not seem always to receive the attention it merits. It is this:

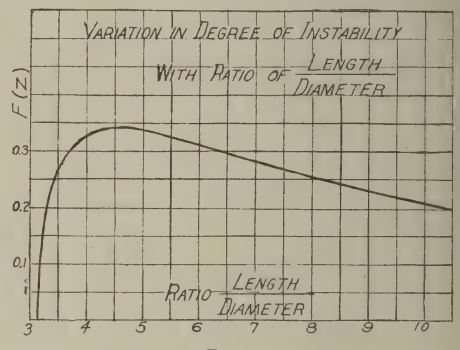

FIG. 2.

Static criteria of stability, such as Plateau's criterion mentioned above, are sufficient only in purely static phenomena, where ample time is available for the instability to predominate. In dynamic cases, at least three things must be considered: (1) the static criterion of stability; (2) the degree of instability, as determined by (*a*) the disturbances by which equilibrium is upset; (*b*) the changes through which the system under investigation will pass while the instability is acting; (3) other forces that may act simultaneously. All of which is summarised in the question: Has the instability a chance to produce its effect before something else happens?

Electronic States of the CN Molecule.

COMPARATIVELY little attention has been paid as yet to the electronic changes involved in the emission of band spectra. In line spectra the study of resonance potentials, of absorption spectra, and of thermal excitation, have all been fruitful in the determination of electron levels. Low-temperature absorption spectra obviously involve as their less excited electronic state the normal state of the absorbing atom, or molecule. Lines, or bands, thermally excited at moderate temperatures, necessarily involve transitions from moderately excited states, very often *to the normal* state of the emitter. Familiar examples of band spectra so excited are the flame spectra of the alkaline earth and copper halides, and of boric oxide; probably many, perhaps all, these involve as an end state the normal state of the emitting molecule; the fact that these bands have not been observed in absorption may be ascribed to the impossibility of

[9] Ollivier, *Ann. de Chim. et de Phys.*, 10, 313, 1907.

otaining the emitting molecules in sufficient con-
ntration in the vapour state at ordinary tem-
.ature.

An examination of the CN bands with these points
i mind gives interesting results. The long dispute[1]
s to whether carbon in addition to nitrogen is
quired for the emission of these bands seems now to
ve been decided in the affirmative.[2, 4] Without
ttempting to review the evidence, the following
portant points may be noted: (1) The supposed
lation between the constants of the red CN bands
d of the first positive nitrogen bands has recently
en disproved[2] by Birge; (2) the (red and violet)
N bands appear in active nitrogen when, and only
hen, carbon compounds are admitted[3]; (3) accord-
g to Freundlich and Hochheim,[4] when nitrogen is
ated to 2100°-2200° C. in a graphite tube, the violet
N bands are emitted in great intensity (according to
. S. King[5] they also appear in absorption at slightly
gher temperatures—about 2500° C.), but are com-
etely absent when nitrogen is heated to the same
mperature in a tungsten furnace; in this work the
d CN bands were not looked for. Evidently in the
esence of nitrogen and carbon above 2000° C., some
mpound is present which can be excited thermally
the emission of the bands. Since the band struc-
re is that of a diatomic emitter, this compound
ust be CN.[6]

The red and violet CN bands, as was shown by
eurlinger, have a common final electronic state.
he latter, it can now be stated, is in all probability
ie normal state of the CN molecule. The thermal
xcitation of the violet CN bands at the moderate
emperature of 2100° C., in spite of the undoubtedly
ery small concentration (see below) of CN molecules,
satisfactory evidence of this. The red and violet
ands, respectively, correspond then to electronic
esonance potentials of 1·78 and 3·18 volts. The
udden appearance of the bands in emission and
bsorption above 2000°, however, requires explana-
ion. One would expect CN to be formed by the
issociation of $(CN)_2$ at high temperatures. This does
ot occur appreciably, however, at or below about
00° C.[7] The matter cannot be investigated experi-
nentally above this temperature, since $(CN)_2$ begins
o decompose into carbon and nitrogen.[7]

The concentration of $(CN)_2$ *in equilibrium* with
arbon and nitrogen must, in fact, from thermo-
lynamic calculations, be excessively small at all low
nd moderate, and perhaps even at the highest,
emperatures.[8] The equilibrium concentration of CN
t low temperatures must be very much smaller still,[9]
ut may be expected to increase with temperature,
robably more rapidly than that of $(CN)_2$. Apparently
bove 2100° it becomes sufficient for appreciable
bsorption and emission of the violet CN bands.
resumably it continues to increase with the tempera-
ure, perhaps until CN becomes a relatively abundant
olecular species. The great intensity of the CN
ands in the carbon arc (temperature about 4000° C.)
is well known.[10] The bands also appear in absorption in the sun and some of the stars.[10] The low resonance potentials of CN indicate, however, a low ionisation potential, so that it is likely that CN is largely ionised at the higher stellar temperatures.[11]

[3] Cf. Lord Rayleigh and Prof. A. Fowler, Proc. Roy. Soc., 86A, 113 (1912); Lord Rayleigh, *ibid.*, 102A, 453 (1923).
[4] E. Freundlich and E. Hochheim, *Zeit. f. Phys.*, 26, 102 (1924).
[5] A. S. King, *Astrophys. Jour.*, 53, 161 (1921); R. T. Birge, *Astrophys. Jour.*, 55, 273 (1922).
[6] The fact that neither $(CN)_2$ nor HCN absorbs these bands—both are colourless—may also be noted in favour of CN. Also, the presence of H_2 in the arc, causing HCN formation, *diminishes* the intensity of the CN bands.
[7] Cf. refs. in Abegg, "Handbuch der anorg. Chemie."
[8] Lewis and Randall, "Thermodynamics" (McGraw-Hill Co., 1923), pp. 592-4. The existence of $(CN)_2$ at low temperatures must evidently be ascribed to a negligible decomposition rate.
[9] This is shown by the non-dissociation of $(CN)_2$ below 800° C., supported by the non-appearance of CN as a chemical entity at ordinary temperatures.
[10] Cf. A. Fowler and H. Shaw, Proc. Roy. Soc., 86A, 118 (1912). The appearance of the CN bands in comets, presumably at low temperatures (as in active nitrogen), may reasonably be attributed to the action of electron bombardment or high-frequency radiation on C- and N-containing compounds which may be present.
[11] There is considerable evidence of an analogy between CN and BO, both chemically unsaturated "odd molecules," and the Na atom. This will be discussed elsewhere. It may be noted here, however, that in all three cases there are nine electrons in addition to the nuclei and K electrons, and in all the resonance potentials are low.

Spectral Theory and the Origin of the Nebulium Lines.

THE fact that the so-called nebulium lines are found to be associated with hydrogen and helium lines only, has frequently been taken as an indication that these lines are somehow emitted by hydrogen or helium, although it has been a great difficulty for this hypothesis that terrestrial experiments always have failed to reveal the lines. The physical conditions prevailing in nebulæ are very probably characterised by exceedingly low density combined with the absence of nearly all possible sorts of disturbing influences, apart from a field of radiation which, however, in only a few cases can be comparable in intensity to that of faint moonlight. Similar conditions of low density may also be essential characteristics of the outer atmospheres of long period variables, of the solar chromosphere, and the upper atmosphere of the earth, in all places of which there appear spectral lines of unknown origin or under anomalous conditions of excitation.

If the suggestion is true that the appearance of the nebulium lines, etc., is due to absence of disturbing influences, atomic theory would suggest that these lines were connected with a faint metastability of certain possible quantum states of the atoms which, under ordinary experimental conditions, is so small that it is broken down by interaction between the molecules in the gas or by the electric current applied. As to *hydrogen* in an atomic state, there appears to be no possibility left open for emission of lines which do not fit into the ordinary Balmer formula. It is, however, of great interest in this connexion that the 2_1 state of the hydrogen atom is exceptional as regards stability, as the transition $2_1 \rightarrow 1_1$ to the normal state is excluded by the selection principle. The stability of this state depends upon the fact that the relativity modifications in the motion of the electron are equivalent to the existence of a small additional central field necessitating the introduction of the azimuthal quantum number k and restricting transitions to such where k changes by $+1$ or -1. If the 2_1 state really possesses some metastability in hydrogen it must be the case to an enhanced degree for helium atoms with one electron only; and similar cases are to be found for the $2S$ term of the parhelium spectrum as well as for other spectra. (Cf. the calcium spark spectrum.)

Ordinarily, we expect that, in any recombination process between a positive ion and a free electron, the ion will in the overwhelming number of cases be in a normal stable state, while the outer electron occupies successive quantum states of the atom. For the special case in which the ion possesses metastable states, as is expectedly the case in helium, the binding process may perhaps take place to a large extent while the

atom, apart from the outer electron, still persists in a higher quantum state. In the special case of helium, we should thus expect that a free electron might be bound while the inner electron resides in a 2_1 quantum state. The spectral lines emitted in such a hypothetical binding process would be different from any lines or combinations in the ordinary helium spectrum and would just constitute a characteristic spectrum emitted by helium under conditions of a strong ionisation and excessively low density.

It would thus appear that the theoretical possibilities of the nebulium spectrum being due to helium are not yet exhausted. The possible existence of a metastable state of hydrogen would further help materially in understanding how hydrogen can show a marked degree of ionisation under the very feeble conditions of excitation in nebulæ, a fact which is evidenced by a marked emission of continuous radiation at the head of the Balmer series observed in several planetaries. This fact and the concordant complete absence of any trace of the hydrogen many line spectrum seem also to offer difficulties to all theories ascribing the nebular lines to molecular compounds of hydrogen and helium, an idea which otherwise would be in harmony with the above trend of thoughts. (Cf. H. H. Plaskett, NATURE, Sept. 15, 1923, p. 392.)

Polarisation of the Light of Rainbows.

IT is quite well known that the failure of Brewster's law in the case of several substances is due to unavoidable imperfections in the polish of the surfaces. Several years ago the late Lord Rayleigh showed, by mechanical separation of surface impurities of water kept in a long metal trough, that Brewster's law did hold good in the case of water treated in this way.

On the morning of August 29, 1924, at about 6.15 A.M., when the sun was about 5° above the horizon, a strong primary bow attended by its strong secondary with the usual colour sequence was thrown on the westward sky. Just before the appearance of these bows, there had been one or two heavy showers, and during the interval the bows were visible it was almost incessantly drizzling. When examined by a nicol, light from the bow appeared almost completely plane polarised. Assuming, then, Brewster's law, and taking 1·33 as the refractive index of water for the mean ray, we find the angle of incidence is 53° 4′ and angle of refraction into the raindrop is 36° 56′ approximately. For one internal reflection, *i.e.*, in the case of a primary bow, we can calculate the total amount of deviation which the incident ray suffers. It is 138° 24′, which is about the same as that calculated in the usual manner. Now the raindrops taking part in the production of bows are for obvious reasons free from surface contaminations, and thus the above observations appear to confirm in a novel way the late Lord Rayleigh's suggestion that in the case of ordinary water, the failure of Brewster's law is due to the attendant surface impurities.

While the above observations were being made, a fresh bow parallel and close to the primary was suddenly developed. This had the same colour sequence as the primary but differed from the latter in intensity of colour and radius. The colour intensity, as judged visually, was slightly less, and the radius slightly greater, than that of the primary bow. But the most noteworthy phase of this phenomenon was that the new bow gradually approached the primary and ultimately merged into it. The whole phenomenon took about two minutes for its completion. The light from the new bow as well showed almost complete polarisation.

So far as I am aware there is no previous record of such a phenomenon, and consequently it is likely to excite much interest and explanatory speculation. So far as I know, the two primary bows may be explained by imagining two parallel rain showers from two gradually approaching clouds until one disappears into the other. A simple qualitative laboratory experiment with glass spheres filled with water, and a strong and steady source of white light, appears to lend support to such an explanation.

I should be much obliged if any reader of NATURE would kindly communicate to me any observations he may possess regarding the phenomena described above.

An Endotropic Fungus in the Coniferæ.

DURING an investigation on the anatomy of the buds of the Coniferæ in 1923, certain features met with suggested the possible presence of an endotropic fungus in the living tissues, but the feature seemed so unlikely that the matter was not then further pursued. Researches on the distribution of potassium in the tissues of *Picea Canadensis* last year, by Miss E. S. Dowding in this laboratory, again brought to light features suggesting the presence of fungal hyphæ in the bud, and showed with certainty the presence of an endotropic mycorhiza in the deeper living tissues of the root. The inquiry was taken up again in the latter part of October, and since then I have found a fungus present in the living cells of the root, stem and bud in the following tissues: phelloderm, cortex, medullary rays, pith and cortical tissues of the bud.

The mycelium may be present as an exceedingly fine system of threads which are seen to penetrate the cell walls and may be massed in convolutions round the nucleus of the cell; they may be present as short jointed threads nearly filling the cells of the young root, and in certain tissues of the bud the hyphæ may assume the condition of large coiled threads frequently applied to the nucleus of the cell. Many of the stages in different tissues strongly resemble the various conditions of the mycorhiza of *Thismia Aseroe* described by Groom (*Annals of Botany*, 1895). An endotropic fungus penetrating the living cells of the root, stem and bud has been found during the last few days not only in *Picea Canadensis* but also in *Larix Laricina*, and I have good reason to suppose that a similar condition also occurs in Pseudotsuga and Abies. That such a condition of symbiosis, possibly obligate, should be present in some and probably a large number of genera of Coniferæ on this continent is surprising and opens up an extensive field of extremely interesting investigation.

During the last few days an examination of the root and stem of *Ledum palustre* and *Vaccinium Vitis-idæa* from this district has been made, and an endotropic fungus has been found similar to that described by Rayner (*Annals of Botany*, 1915) in European material. An account of the leading features of the coniferous material will be published immediately, and a more detailed paper dealing with the possible infection of the seed and other matters will be published later.

Molecular Dimensions of Celluloid.[1]

RECENTLY we have had occasion to make thin films of celluloid by the previously known method of dissolving the celluloid in amyl acetate and allowing a single drop of the solution to fall on a clean water surface. With solutions sufficiently dilute, as the amyl acetate evaporates interference colours appear in practically uniform sheets of colour over the entire surface which change from red to violet and then the film becomes colourless. Some of these films were deposited on optically flat glass and their thickness determined by an interferometer method by C. G. Peters, of the Bureau of Standards' staff.

In this manner films so thin as 30 angstroms were measured. The solution from which these were deposited contained one gram of celluloid dissolved in four hundred grams of amyl acetate. Thinner films than these could not be measured directly, but those made from a solution containing one gram of celluloid in eight hundred grams of amyl acetate were sufficiently tenacious to hold together and adhere to the finger. With still further dilution—one gram of celluloid in twelve hundred grams of amyl acetate—as the last traces of the amyl acetate evaporated, a vibration or quiver was seen to pass over the surface of the water and the film simultaneously broke into minute particles of celluloid.

Assuming that the films decreased in thickness in proportion to the dilution of the solutions, since their area remained practically constant, this means that the films which were just too thin to hold together were approximately 10 angstroms thick. This value agrees with that calculated directly from the density of celluloid, the concentration of the celluloid solution and the area of the film on the water surface. Since the thinnest stable films must have been at least one molecule thick, these experiments indicate that the molecular complex of celluloid is not more than 10 angstroms in diameter. This value is in accord with similar results obtained on oil films[2] and other organic substances.[3]

Mercury and Helium.

IT is known that under some conditions not clearly defined or understood, mercury and helium may become so intimately associated that the separation of the one from the other is difficult. According to prevalent views, helium is a highly inert gas, and is therefore incapable of combining with other elements; hence it appears that helium can in some way not known act as a "carrier" of mercury.

For some years past I have been experimenting with mercury and various gases, including hydrogen and nitrogen. The results obtained led me to try similar experiments with mercury and helium; these last are now almost concluded. Briefly, the findings are as follows. Under certain conditions and in the presence of an electric glow discharge, mercury and helium combine to form mercury helide. The helide is a stable compound, and is not readily decomposed except at or above a bright red heat. As the formation of the helide progresses, a corresponding decrease in the volume of the helium employed takes place. On heating the mixed gases (helium and helide) to the required temperature, the original volume of the helium is restored. The helide is but slightly absorbed by charcoal cooled in liquid air. The refractive index of the mixture of helium and helide, as observed by a Jamin interferometer, increases continuously during the formation of the compound. When used in a vacuum tube of the form employed for spectrum analysis, mercury helide is gradually resolved into its elements. At the moment of activating the coil, the mercury green line (W.L. 5460·7) is invisible; then as the coil is worked, the line, at first faint, steadily increases in strength, and in some cases ultimately becomes quite bright.

Judging from these results, it appears almost certain that the associated mercury detected by earlier observers, has been present as helide, the conditions having been those under which that compound could be formed.

I have not yet carried out a quantitative analysis of the mercury helide, but a plan for doing so has been made, and is now being perfected. I hope shortly to give a detailed account of my work and conclusions.

Optical Separations and Atomic Numbers.

IT has been recently shown (Millikan and Bowen, *Phys. Rev.*, 24, 1924) that in optical spectra due to atoms having similar electronic configurations, the doublet and triplet separations vary according to the relativity X-ray formula:

$$d\nu = K(Z-s)^4$$

where $d\nu$ is the doublet (or triplet) separation, K is $(0{\cdot}365 \times 2^3)/n^3$, n being the total quantum number appropriate to the orbits giving rise to the separation, Z the atomic number, and s the screening constant, which varies, becoming smaller, for example, in passing through Li I, BeII, BIII, CIV.

This formula has been applied to doublets and triplets generally, and the values of s obtained tabulated. On plotting curves it is found that the values of s within the same group are directly proportional to the atomic number, this proportionality holding also for the ionised elements. Moreover, the slopes of the graphs are very nearly the same for all groups. So far, straight lines have been obtained for groups I*a*, II*a*, II*b*, III*b*, II*a* spark, II*b* spark; others are being investigated. This linear relationship should be of importance in assigning spectral series; and it is being applied in this way. The matter will appear shortly in more detail.

Eolithic Ornament and Art.

IN the English translation of Prof. Hugo Obermaier's book "Fossil Man in Spain" (Yale University Press), just published, there appears, on page 9, the following statement. "But some—among them Boucher de Perthes, Dharvent, . . . and J. R. Moir, went further, and proclaimed the existence of Eolithic ornament, and art."

This, so far as I am concerned, is entirely incorrect. I have never "proclaimed" a belief in the existence, in any form, of Eolithic ornament and art, nor do I believe that evidence which would make such a belief inevitable has, as yet, been discovered.

As Prof. Obermaier's book will, in all probability, be widely read by English readers, I regard it as necessary to make the above correction.

The Carbon Atom in Crystalline Structure.[1]

By Sir WILLIAM BRAGG, K.B.E., F.R.S.

IT is one of the great purposes of research to be able to explain the properties of materials in terms of the properties of their parts. The division into parts may be carried to various degrees of fineness; and the nature of the research, its methods and difficulties, and the expectations of success will depend on the division that is attempted. The properties of a piece of steel may to some extent be explained in terms of the small visible particles, crystalline or not, of which it is composed; the degree of division is determined by the power of the microscope, and results of great value are obtained within this range. But we may have, as a higher ideal, the hope of explaining the qualities of steel in terms of the properties of the atoms of iron and carbon and other constituent elements. This division is far finer than the other; but obviously far more complete and satisfying. The difficulties are great, but so also will be, we may be sure, the ultimate success. Generally it must be our aim to explain the properties of all materials in terms of the atoms, remarkably limited in kind, of which the world is made.

Some progress towards the ideal has been made in the case of the gas and the liquid states; the great effort is yet to be made in the case of the solid. The moving particles of a gas are free from each other's influence for the most part of their time; they can be treated as projectiles the rare encounters of which are but slightly affected by the special and peculiar attractions which they exert on each other when very close together. The properties of gases are to a certain extent explainable in terms of a pure kinetic theory. Complications arise when from any cause the times during which the atoms or molecules are under each other's influence become relatively important, and the consequences depend on the individual peculiarities.

So also in the case of liquids much can be explained on a purely hydrodynamical theory, especially when the ties between atoms and molecules can be dissolved and re-formed continually without waste of energy in the form of heat, that is to say, when there are no viscosity effects. But when viscosity is to be taken account of, then the peculiar and individual actions of the atoms and molecules must be treated as effective. Still more, the phenomena of surface tension are direct manifestations of the forces that the atoms exert on their neighbours; and so in general are all the effects studied by the physical chemist. We are yet very far from being able to unravel them.

It is true that the associations and dissolutions of chemical action are due directly to the characteristic forces exerted by the atoms; and that chemical studies afford a most important means of examining them. Nevertheless, we want more than chemistry gives us if we are to reach our object. For example, we are far from linking up the properties of quartz with the known chemistry of silicon and oxygen.

In general, we know very little of the relation between the properties of the solid material and of the atoms of which it is built. Of the relation between the molecule and its constituent atoms we do know something, thanks to chemical study. But the wide field of solid structure is in this respect almost unexplored. The reason for this is very simple. The properties of the solid depend upon the structural arrangement of its component atoms, and the arrangement is, at the first attempt, as we may say, crystalline. When groups of atoms or molecules associate and form a solid, they arrange themselves in a regular pattern; the unit of pattern containing only a few groups, usually two, three, four, six or other small numbers. The arrangement is so uniform and so exact as to imply that the group has a definite and characteristic shape, or, in other words, that the forces which one group, atom or molecule exerts on its neighbours are such as to place them at proper distances from itself, and in proper orientations. The crystal is the direct expression of this tendency and is a far more prevalent form of matter than we had thought. The large crystals that we see with our naked eye, and even the small crystals which the microscope reveals to us, are only the favourable cases. Below all that we can see in any way is a universal tendency to crystallisation which the methods of X-ray analysis are now showing to us. The solid which appears to us to possess none of the properties of the crystal is usually a very viscous fluid, or a disordered mass of minute crystals. The crystal is the simple body, the so-called isotropic body is the complex. Consequently, it is the crystal that must first be mastered.

It is only within the last ten years that the direct study of crystal structure has been possible, and the way to this huge field of inquiry been thrown open. The X-rays, to put it simply, if somewhat crudely, are a form of light ten thousand times finer than visible light, and we are now able to see, indirectly it may be, the actual arrangement of the atoms. Here is our chance of making this supreme analysis. We have before us a widespread research, in the course of which we must examine crystal after crystal, learning its structure, that is to say, the pattern according to which its constituent atoms are arranged, and examining the way in which the properties of the individuals determine that pattern; and in turn the pattern determines the elasticities, rigidities, conductivities, dielectric capacities and every other characteristic which the crystal possesses. After that, follows in its turn the crystal conglomerate, the isotropic solid.

An especial interest is attached to all that we can discover by the new methods of crystal analysis concerning the nature and properties of the carbon atom. It is not one of the more common elements. While oxygen is calculated to form half the materials of the earth's crust, silicon a quarter, and aluminum about a sixteenth, only about a thousandth is composed of carbon. But it is the carbon atom which more than any other impresses its character on the materials of which living bodies are composed. The very term, organic chemistry, which is given to the subject that is largely occupied with the study of the carbon compounds, is an expression of the importance of the carbon atom in the living organism. Not only is the carbon

[1] Address delivered at the University of Pennsylvania, on September 18, on the occasion of the celebration of the centenary of the Franklin Institute. Reprinted, with slight modifications, from the Journal of the Institute for November 1924.

atom of supreme importance in the constitution of our bodies and of their unconscious actions, but also in a great proportion of the external activities in which we are engaged. We must be especially eager to know what we may learn of the behaviour of the carbon atom when it takes part in the constitution of the solid body, and in the first place of the crystal which is the simplest form of the solid. The only fact which makes us hesitate is the vastness of the number of known crystalline compounds, giving us a bewildering choice of material on which to work.

We come to this study with certain expectations founded on the large labours of the organic chemist and their rich harvest of results. We expect the carbon atom to display, for example, a definite tetravalency, a power of attracting to itself under certain circumstances, at least four other atoms and no more, all bound in a similar way to the central carbon; as, for example, when the carbon atom draws to itself four atoms of hydrogen and the methane molecule is formed. Yet, in other circumstances, the carbon atom seems fairly content with a smaller number, as when in the benzene ring each carbon is attached to two other carbons and only one hydrogen, and the benzene molecule has very little general attraction for another benzene molecule. Again in the carbon dioxide molecule, the carbon atom is satisfied by the companionship of two other atoms only, and we should like to know what rearrangement has been made of its activities to permit the formation of this self-contained molecule, so independent that it forms a gas. Also, what further change has been made when the molecule of carbon monoxide is constituted? In other words, what is the explanation of the single, double, and triple bonds known to the chemist? We hope to be able to throw light on all these conditions, and the questions to which they give rise, by the study of the carbon atom as it is built into the crystal, where we can examine the exact nature of its environment and can relate thereto the properties of the crystal.

There are two crystalline forms composed of carbon alone, diamond and graphite, and we naturally turn to their examination first. The diamond structure was, in fact, one of the first to be examined by the new methods. Its structure is very simple and symmetrical, and answers at once our expectation that we should find in some circumstances a perfectly tetravalent behaviour. Each carbon atom is surrounded by four others, which are grouped about it in perfect symmetry; the atom shows no attraction for more than four. A sphere can, of course, be surrounded by twelve other similar spheres, and if the attraction between any two atoms could be represented merely by a central force, we should expect the close packing which gives the full quota of neighbours. Since there are only four, the force exerted by one carbon atom on another cannot be represented by central forces only. Further, the hardness and rigidity of the diamond show us that the forces are mutually oriented; that they are primarily exerted along four lines drawn from the centre of a tetrahedron to its corners and that there is a strong resistance to any relative change in those directions. All these new points are in excellent agreement with known chemical facts. The carbon atom is to be represented by a tetrahedron rather than a sphere.

The disposition of the atoms in the diamond shows that they may be divided into two classes, any member of one class being the reflection of the other—with appropriate shift—in any one of three planes which are the cube faces of the crystal. To put this in another form, each diagonal of the cube crystal passes through the vertex and the middle of the base of each class of atom, but members of the two classes face opposite ways. The X-rays detect the difference between the two kinds, from which we conclude that the scatterers of the X-rays participate in the tetrahedral grouping. Yet the difference is only slight, so that if it is the electrons that scatter, they are close to the centre, which seems unlikely; or else they have an extended movement about their average positions at the corners, so that their diffracting effect is small; their action is like that of broad faint rulings on a diffraction grating.

The other crystal of pure carbon is graphite. There is no clear evidence at present of the existence of any other form, although certain curious carbon materials have not been fully examined. The structure of graphite has recently been re-examined by Bernal, who was able to obtain single crystals of sufficiently perfect form. The results of his work show that graphite is a hexagonal crystal, as Hull had supposed from an examination by the Lowder method. It consists of layers of carbon atoms, each layer separated from the next by 3·40 Å.U., as has long been known. In each layer, the carbon atoms are arranged in a hexagonal network; the long uncertain point as to whether the atoms of one sheet are all exactly in one plane or are in two planes making a puckered network, seems now to be decided in favour of the former alternative, as Debye has suggested. In this case, each carbon atom is very strongly tied to three neighbours, all in one plane; the distance between the centres is 1·44 Å.U. as against 1·54 Å.U. in the diamond. The distance between a carbon atom in one layer and its nearest neighbour in the next is more than twice as great.[2] The curious properties of graphite show that the forces between atoms in the same sheet are exceedingly strong, while the forces between sheet and sheet are very small. It is clear that the carbon atom is now exerting its attraction on other atoms in quite a different manner from that which was followed in the diamond. If the electrons are in some way responsible for these forces, their arrangement must have been altered. The atom is no longer tetrahedral.

The extraordinary success of Bohr's theory in regard to radiation is a constant inducement to attempt a correlation between his arrangement of electron orbits with the display of the atomic forces, although it does not seem possible at present to make more than vague and preliminary attempts in this direction. According to Bohr, there are four electron orbits which we may naturally associate with the tetravalency of the atom; but the four are not all alike, being different, two and two. Thus the tetravalency is not fully symmetrical. The radiating carbon atom which is the subject of the theory is not, however, attached to other atoms, but is free; and we may well suppose that the internal

[2] Since this was written, a paper by Hassel and Mark has appeared in the *Zeitschrift für Physik*, describing experiments which lead to exactly the same result as that of Bernal. The latter's paper appears in the Proceedings of the Royal Society.

arrangements are modified by structural requirements. There may be a real difference, implying perhaps a different energy content between the free atom with its two pairs of outer orbits, the atom in graphite with three like orbits and one odd, and the atom in diamond with all four alike. The electron of the odd orbit in graphite would naturally travel far and be loosely attached to the nucleus; and in this, as has been suggested by Shearer and Bernal, we may find the explanation of the colour, the opacity, and the conductivity of graphite.

We now come to cases in which other atoms beside the carbon enter into the structure; and first to calcite. The X-ray analysis shows that the carbon atom is now surrounded symmetrically by three atoms of oxygen, all alike.

The compact group of one carbon and three oxygens possesses a double negative charge; the calcium atom possessing the corresponding amount of positive electricity. It has been suggested by Kossel that the arrangement is governed by the tendency for the oxygen atoms to surround themselves in each case by the full complement of eight electrons, and that this is effected by stripping the calcium atom of two electrons and the carbon atom of four. On this theory, there is no parallelism with the graphite structure, though in both cases the carbon atom is surrounded by three other coplanar atoms, similarly situated. The carbon atom has now lost all four of the electrons that were moving in outer orbits and is reduced, in external appearance, to helium. It is to be treated as exerting a central electrostatic force due to a positive charge of four units.

It is well known that a vast number of organic substances are based on a substructure consisting of a ring of six carbon atoms, or a chain of carbon atoms of any length. The simplest ring compound is the famous benzene molecule; benzene does not, however, lend itself very readily to analysis because benzene is liquid at ordinary temperature and when frozen does not form good crystals. But there are the two substances, naphthalene and anthracene, of which the former has been imagined by the organic chemist to consist of a double ring, represented by two hexagons in the same plane, having one side and two corners in common. The latter consists of three hexagons in a line, the naphthalene model extended by one more hexagon. Both these substances crystallise well, a very marked characteristic of each being the tendency to split into thin flakes. All these molecules are bounded by hydrogens. They must be considered as simple subjects for attack, because the ring is so common a feature of organic substances, and the single, double and triple rings form a series of comparable members. A curious point of obvious interest is the connexion of each carbon atom with three, and only three, other atoms. Why has the fourth bond apparently disappeared?

The X-ray analysis shows that the unit of pattern of both naphthalene and anthracene contains two molecules arranged so that their long axes are parallel to one another and that they are the reflection of each other in the single plane of symmetry which the crystal possesses. In fact, the crystal can be considered as a set of parallel flakes, like the monomolecular layers of Langmuir. In each flake the molecules stand not quite at right angles to the flake, but lean over like wheat in a field blown by the wind. The difference between the anthracene and the naphthalene structures lies only in the length of the molecule, which makes the flake thickness of the former greater than that of the latter. Moreover, the actual increase in length which is found by the X-ray measurement is exactly what it should be if, in the first place, the one molecule consists of three benzene rings in a row and the other of only two, according to chemical theory, and in the second place, the width of the ring is the same as that of the carbon ring which is found everywhere in the diamond structure. We might suppose, in fact, that the molecule of naphthalene as built into the crystal structure was simply carved out of the diamond without alteration and then fringed with hydrogen atoms. A similar set of atoms carved out of the graphite flake would do equally well so far as length is concerned, because the graphite layer is, according to Bernal, the diamond layer pressed flat without any sideways extension. But if the carbon atoms were in the supposed graphite condition, it might be expected that naphthalene would be a conductor and be opaque like graphite, which is not the case. The direct analysis itself is not yet able to say whether the three attachments of each carbon atom to its neighbours in the same molecule are all on one plane. It is to be remembered that there are attachments between each molecule and its neighbours in the same layer, but these must be far weaker than the bonds binding together the atoms in the same molecules; they are stronger, however, than the end-to-end attachments which break on the cleaving of the crystal. These last must be feeble because the crystal cleaves so easily.

So far, therefore, the result of the analysis of these crystals is, in the first place, to give confidence in the existence of a mutual support between the established organic chemistry and the new methods of analysis; and to show us also how closely the behaviour of the crystal may be connected with its general structure. As to details, the indication seems to be that the carbon atom has—at least nearly so—the same characteristics as the atom of the diamond; but that one of the four valencies is unused. We have even some grounds for saying that the unused valency, or the unoccupied corner of the carbon tetrahedron, is that which lies on the face of the molecule, not on its edge. The crystal of naphthalene tetrachloride, *i.e.* naphthalene with four added chlorine atoms, shows the same structure as that of naphthalene, and has very similar dimensions except that it has broadened by an amount which would correspond closely with the result of adding the chlorines at the places indicated.

Measurements have been made of some of the dimensions of other crystals containing ring molecules, and the results fit in, so far as they go, with the idea that the ring is an actual structure of definite dimensions and form, slightly altered it may be by additions or substitutions of other atoms or groups of atoms, or strained because it has to be fitted into its place in the crystal, nevertheless recognisable in its different circumstances, as the chemist would expect. To settle these points more satisfactorily, to turn guesses into certainties is, of course, the work that is before us.

Very interesting results are obtained by Müller and

hearer from the study of the long-chain molecules of he fatty acids, hydrocarbons, and similar substances. t appears that when these substances in the solid tate are pressed on to a flat surface, they form flaky rystals like graphite or naphthalene, and it becomes asy to measure the thickness of the monomolecular ayer. The experimental results are beautifully definite, nd their interpretation can be given with great chance f being correct. It seems probable that the molecule s perpendicular to the layer, not slanting. If it were he latter, one would expect the amount of slant to be ariable so that it would not be possible to connect he thickness of the layer with the length of the nolecule only. Now, it is a remarkable fact that the hickness of the layer grows at a uniform rate as the hain is increased by the addition of carbon atoms, and hat for very nearly all, if not all, the different kinds f chain molecules that have been examined, this rate has one or other of two values. For every two carbon atoms that are added the increase in length is either 2·50 Å.U. or 2·00 Å.U. very nearly.

If we were to suppose that every carbon atom in the chain had four points on it, disposed like the corners of a regular tetrahedron, at any one of which an attachment could be made to a neighbour, in other words, if we supposed the atom to be as in diamond, then a chain of carbon atoms would take one or other of three forms, one of which is a screw. Putting the distance between the centres of two carbon atoms equal to the distance found in the diamond, namely, 1·54 Å.U., it can readily be calculated that the length of chain *A* (Fig. 1) is 2·50 Å.U. for every two atoms

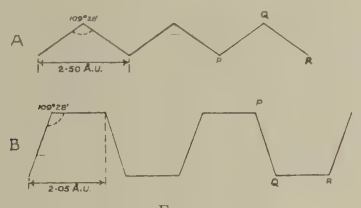

FIG. 1.

added, and of chain *B*, 2·05 Å.U. The agreement with experiment seems to be more than a coincidence, and it may be provisionally assumed that in these chains either the *A* or the *B* form is adopted, and the linkage of carbon atoms with their neighbours is on the diamond plan. In other words, if *PQR* are the centres of three atoms, the angle *PQR* is equal to the angle between two of the lines joining the centre of a tetrahedron to the corners.[3]

One of the most striking results is the fact that the length of the main body of the chain is independent of the nature of any additions to its ends or replacement of any of its side hydrogens by an oxygen atom as in the ketones. Even the removal of two or four hydrogens from the body of the chain leaving two carbons connected, respectively, by a double or a triple bond, makes no appreciable difference in the length. It would not have been a matter of surprise if such treatment had caused a bend in the chain, on account of the relative shifting of points of attachment on the carbon atom that might be due to other points of attachment being unused. The removal of a pair of hydrogens from the chain makes no more difference to the chain than the stripping of an opposing pair of leaves from the stem of a plant.

A very curious point in the behaviour of the long chains is their apparent doubling in length when one end is formed of a so-called active group, as, for example, in the case of the fatty acids. When this is the case two chains join end to end, the active groups being together, and again the result is just the same as if two sticks were joined into one, the process of joining being concerned with nothing beyond the two active ends. This form of structure is illustrated in a very interesting way in the X-ray spectra. If a section is made of a substance consisting of layers of these doubled molecules, so as to show their stratification, then there will be a uniform distribution of diffracting centres—electrons—throughout the mass, with alternating thin layers of excess through the active ends, and thin layers of deficiency through the inactive ends, the methyl groups. This has the curious effect of intensifying the odd orders of the diffraction spectra. To understand this, it is only necessary to remember that if we were to make a series of fine rulings on a diffraction grating which exactly interleaved the stronger original rulings, the result would be the strengthening of the even orders; such an effect is found in the case of rock salt and was an important help in the determination of its structure. If now the additional rulings, instead of being like the original but weaker, could be of reversed effect, a deficiency instead of an excess, it would be the odd, not the even orders that would be strengthened. The same effect is found in the case of the ketones. When the substituted oxygen is in the middle of the chain, each layer of hydrocarbon molecules shows a generally uniform distribution of electrons with an excess at the middle where the oxygen atom is placed, and a deficiency at either end. When the substituted oxygen is not in the middle, the reinforcement of the odd orders disappears.

These many observations of the behaviour of the long-chain molecules seem to point to the conclusion that the carbon atom in the chain is, like the carbon atom in the diamond atom, possessed of four points of attachment regularly disposed about it, and that the non-use of one does not alter the disposition of the others.

It is scarcely necessary to consider in any detail the points given by structures like tartaric or succinic acid as to the behaviour of carbon atom. It is enough to say that, while the full interpretation may be yet to come, the general indications are in accordance with what has already been said.

These first tentative conclusions as to the behaviour of the carbon atom in the solid body are of interest, in spite of the fact that so little, relatively, has been accomplished in the solution of the structure of organic crystals. What remains to be done must have great consequences, and what little has been done already seems to possess many points of novelty and of interest, and these two facts taken together may be sufficient justification for this attempt at a review of the present position of the inquiry.

[3] A minute but perfect crystal of stearic acid has recently been examined by the X-ray method by R. E. Gibbs, who has found it to belong to the monoclinic class. The long molecules are not perpendicular to the cleavage plane, but are inclined at about an angle of 63°. This result is not necessarily in contradiction with any of the above suggestions.

The Biology of the Suez Canal.

THE Cambridge and Royal Society Expedition which set out last September to investigate the biology of the Suez Canal (see NATURE, October 4, p. 520) arrived at Suez at the end of the month, and at once went under canvas on the shores of the Bitter Lakes, being provided with boats, etc., by the generosity of the Canal Company. Here the members remained for four weeks, afterwards proceeding to Suez for a like period. They are now at Ismailia living on a house-boat lent by the Canal Company, this being towed from place to place as desired. Later they propose to move to Port Said for the last four weeks of their stay.

The Bitter Lakes, which are about 36 kilometres long by 12 broad, becoming much narrower to the south, yielded surprising results. There is a central area of about 6 fathoms, that overlies an extensive salt bed. This is covered by black mud, which proved to be absolutely devoid of life, although the density and temperature of the water immediately over it are relatively little higher than elsewhere; it may be presumed, however, that the salinity of the Lakes must have decreased since the Canal was opened. This deeper ground merges into extensive areas of shallower waters (0-3 fm.) by the shores, the surrounding land being almost typical desert. The waters were investigated in 1882 by Keller, who found them almost devoid of life, while Fox now writes enthusiastically as to the richness and variability of the organisms of this shore region. Keller found no anemones or echinoderms, 1 species of crab, 2 sponges, and a very few worms, while Fox records anemones as very common, also a few alcyonaria, echinoderms represented by sea urchins, starfishes, brittle stars, and holothurians, many species of crabs and sponges, with an abundance of worms and representatives of most other groups of organisms, including excellent soles. Bare sand, almost devoid of life, is found in patches, but most of the bottom is covered with a rich growth of algæ and phanerogamic plants. There is a striking average increase in size of some of the individual species of animals as compared with those which Fox previously collected for research purposes at Suez, the most striking being a large black Synapta about 45 cm. long as compared with the usual length of 25 cm. There proved to be considerable diversity of fauna and flora off different shores of the Lakes, and contiguous patches of the bottom were often found to carry different plants and animals, so that the mapping out of the bottom regions proved a task of great difficulty.

"The salt pools on the shores," writes Mr. Fox, "although interesting, have been disappointing owing to the poverty of their fauna. All contain one fish and one gastropod, both species in great numbers. There is no plankton and no other animal. The fish and mollusc both feed on algæ. The surprising thing is the high salinity which the fish and mollusc endure. My hydrometer registers 1000 in distilled water, 1204 in saturated salt solution. The Red Sea off Suez is 1031, the Bitter Lakes 1035-1045. These fish and molluscs live happily in 1175." (These are relative figures that may require adjustment for temperatures, etc.)

At Suez the Expedition has been mainly concerned with collecting the fauna and flora for comparison with those of the Bitter Lakes. Exact data as to temperatures, salinities, acidities, etc., have been obtained. There would seem here to be greater variability in the bottom life as compared with the period antecedent to the opening of the Canal. For this reason the Expedition has confined its work to ten selected stations, mostly with soft bottom, only once having visited the "coral" reefs which lie about 3 miles to the south. The greater part is sand; phanerogamic plants are uncommon, and algæ almost absent. The latter, however, occur abundantly under the piers, and Mr. Fox discusses how far the general absence of algæ in the Gulf of Suez may be due to an inhibition produced by the intensity of light, the possibility of this as the chief factor being largely discounted by the strong growth of plants in the Bitter Lakes. The Expedition has also studied with great care the organisms attached to vessels, to piles, and to buoys, cleaned on known dates, and has put out wooden floats. These latter should give data both as to the factors helping in the distribution of the organisms and as to the rates of growth of many forms.

In his comparison of the two regions he has so far studied, Mr. Fox concludes that the fauna on the piles of piers is equally abundant, "but the shallow bottom and coast fauna is more abundant in the Lakes. It seems to me that the richer Lake fauna may depend on the bottom, which is mostly sand mixed with mud. On this the phanerogamic weed grows in abundance and gives cover to animals. Further, detritus feeders like mud. In the Bay of Suez, on the other hand, the shallow bottom is more often sand. There are small areas of sand in the shallows of the Bitter Lakes, and these are devoid of weed and very poor in animals, as at Suez. The difference in richness then may be due to a difference in bottom. The striking facts about the lakes would be that (1) the higher salinity does not prevent a rich varied fauna, (2) it does not inhibit growth in size, (3) there are peculiar effects, such as the sex of Neptunus, almost all males."

The work of the Expedition has clearly been much expedited and made far pleasanter by the kindness, generosity, and personal interest that has been taken in it, not by the directors alone, but by all the officials of the Canal Company. They have lent boats and camping equipment, carried mails and helped in the commissariat. The head of the Coast Guards has lent launches, and the officials of the Government have uniformly been friendly. The Canal Company clearly has an area under its control of great scientific interest, if periodically examined. The present Expedition can only, at most, map out its different faunistic regions, and it will remain for a further expedition to examine these quantitatively, so that science may get the full value of the present enterprise.

J. STANLEY GARDINER.

The Coming of Age of Mechanical Flight.

ON December 17, 1903, twenty-one years ago, the famous brothers, Wilbur and Orville Wright, made their first flights with a power-driven aeroplane. Model steam-driven aeroplanes had flown before, and there is some evidence of the partial success of Clement Ader's *Avion* in 1897. But the Wright brothers were the first human beings to rise in the air in a power-driven flying machine and to descend in safety. Altogether four flights were made on that memorable day in 1903, the first lasting 12 seconds and the last 59 seconds. There were only five spectators present on the sandhills at Kitty Hawk, North Carolina, when the flights were made, but there appears to be no question of the correctness of the facts. December 17 is, therefore, regarded as one of the most important dates in the history of mechanical flight and is known in the United States as Aviation Day.

The machine with which the remarkable feat was achieved was a biplane fitted with a petrol engine made by the Wrights. The engine weighed about 7 lb. per horse-power, and the total weight of the aeroplane was 750 lb. Prof. S. P. Langley, who had devoted himself to the scientific investigation of the problems of flight, ran the Wrights very close, and had his machine not been damaged when being launched at two trials made on October 7 and December 8 of the same year, the honour of building the first machine to fly with a human being aboard might have been his. It was Langley's early experiments, and his belief in the possibility of human flight, which were among the influences that led the Wrights to undertake the preliminary investigations that preceded their actual work.

The success of the Wright brothers was largely due to their thorough study of what had been done before, and the interest attaching to the twenty-first anniversary justifies a brief review of the history of the aeroplane. Foremost among pioneers must be placed Sir George Cayley, sometimes called the father of British aeronautics, W. S. Henson, and J. S. Stringfellow. Of the work of Henson and Stringfellow at Chard, in Somerset some eighty years ago, there are many relics in the Science Museum, South Kensington, while the Smithsonian Institution at Washington contains Stringfellow's engine of 1866. The inauguration of the Royal Aeronautical Society in 1866, and the holding of the first Aeronautical Exhibition in 1868, emphasised the growing interest in the subject, and these events coincided with the earliest experiments of Otto Lilienthal. The names of Le Bris, of Alphonse Penaud, and of Clement Ader belong to a nation which was to witness some of the most splendid flying exploits. Langley's work began in 1887, and the year 1896 saw the flight of his steam-driven model. To the 'nineties also belongs the wonderful gliding experiments of Lilienthal in Germany, Pilcher in England, of the veteran Octave Chanute in the United States, and of Capt. Ferber at Fontainebleau.

It was with a knowledge of what had been accomplished by these pioneers that Wilbur and Orville Wright began their work. Born respectively in 1867 and 1871, the Wrights as young men had a bicycle business in Dayton, Ohio, and it was there they turned their attention to gliding and flying. The summer of 1900 saw their first experiments on the Kill Devil Hill sandhills, which were repeated the two following years. In the course of these experiments, says Col. Lochwood Marsh, they "confirmed Lilienthal's theory of the reversal of the centre of pressure on cambered surfaces at small angles of incidence: they confirmed the importance of high aspect ratio in respect to lift: they had evolved new and more accurate tables of lift and pressure on cambered surfaces: they were the first to use a movable horizontal elevator for controlling height: they were the first to adjust the wings to different angles of incidence to maintain lateral balance: and they were the first to use the movable rudder and adjustable wings in combination." The three summers given to gliding were followed by three years' experiments on power-driven machines. In 1903 they made their first flight; in 1904, for the first time, a circle was completed in the air; and in 1905 Wilbur Wright flew a distance of 24 miles at 38 miles an hour, the first successful long flight.

Meanwhile, a band of devoted French pioneers, including Ferber, the Voisins, Farman, Blériot, and Delagrange, quite independently approached success, and on November 12, 1906, in the Bois de Boulogne, the Brazilian, Alberto Santos Dumont, made the first officially recorded flight in Europe. From this time on, record has succeeded record, inventions, investigations, and accidental discoveries have multiplied apace, and the small band of pioneers has become an army.

The fine flight of Orville Wright at Fort Meyer, U.S.A., together with the displays of Wilbur Wright at Le Mans in 1908, gained for flying a popularity hitherto unknown, and the following year saw Blériot cross the English Channel, Cody make the first flight in England, and the meeting of the masters of flying at the famous Rheims gathering. It was in 1910 that Paulhan and Grahame-White had their great struggle for the *Daily Mail* prize of 10,000*l.* for a flight from London to Manchester. Many casualties, however, had to be recorded in these early days, and among them were the deaths of the Hon. C. S. Rolls at Bournemouth, and of Georges Chavez, who on September 23, 1910, flew over the Alps in a Blériot monoplane, only to meet his death in the hour of triumph.

Two years later came the formation of the Royal Flying Corps, and in 1914 the aeroplane took its place on the battlefield as an engine of war. In August 1914 the British Air Services mustered 272 machines. Four years later there were more than 22,000 efficient machines, and new ones were being delivered at the rate of 90 daily. The advances made during the War were summarised by Sir J. E. Petavel in his address to the Bournemouth meeting of the British Association in 1919. Speeds had risen from 80 miles an hour to 140 miles an hour, and the engine horse-power in a single machine had been increased from 100 to 1300.

With the cessation of hostilities came the exploration of the possibilities of commercial flying. In May 1918 a mail service was started between Washington, Philadelphia, and New York, and 1919 saw the inauguration of the London to Paris service. The same year saw the crossing of the Atlantic via the Azores

of the American flying boat NC4, piloted by Lieut.-Commander Read, and the great flight by Alcock and Whitten-Brown in the Vickers-Vimy machine which has now passed into the possession of the British nation. To the same period belongs the feat of Godoy, who crossed the Andes at a height of 19,700 feet, and the first England to Australia flight by Ross-Smith and his brother and two mechanics. With continents and seas crossed in many directions, the circling of the earth was only a matter of time. To accomplish this, however, meant the expenditure of a large sum of money. Surveys had to be made, stores collected, and routes patrolled. Of Squadron-Leader Maclaren's glorious attempt, and the splendid achievement of Lieuts. Smith and Nelson, of the United States Navy, during the present summer, there is no need to write. It was in the United States that the aeroplane was born, and there can be no grudging of the United States her round-the-world-triumph in the year which sees its coming of age.

Current Topics and Events.

On December 13 occurs the bicentenary of the birth of the celebrated German natural philosopher, Franz Ulric Theodor Aepinus, remembered to-day for his "Tentamen Theoriae Electricitatis et Magnetismi," published at St. Petersburg in 1759. Born in Rostock, Saxony, Aepinus was descended from a leading theologian of the Reformation. After studying medicine, he devoted himself to mathematics and physics, and at an early age became a member of the Berlin Academy of Sciences. Like many other foreign men of science, he was attracted to the Russian capital, and became attached to the Imperial Academy of Sciences, inaugurated by Catherine I. on the plans of Peter the Great. Aepinus in 1757 was appointed to a chair of natural philosophy, afterwards became a tutor in the royal family, and endeavoured to found schools throughout the empire. In later years, like his great contemporary, Euler, he was patronised by Catherine II. He died on August 10, 1802, at Dorpat in Livonia, whither he had removed four years earlier. He wrote memoirs on mathematics, astronomy, optics, and mechanics, and in 1764 created great interest by a discussion of the transit of a planet across the sun's disc. Founded upon a modification of the single-fluid theory of electricity, his "Tentamen Theoriae Electricitatis . . . " has been described as the first systematic and successful attempt to apply mathematical reasoning to the subjects of electricity and magnetism. He also indicated the theory of the electrophorus, which, however, was constructed by Volta.

In the middle of the last century the name of Alexis Perrey of Dijon was scarcely less known as a student of earthquakes than that of his contemporary Robert Mallet. The annual catalogues that he compiled, his regional memoirs on earthquakes, and the three laws which he stated as governing the periodicity of earthquakes were widely known. Perrey was the personal friend of such men as Ampère, d'Abbadie, Cauchy, Elie de Beaumont, and Quetelet. Yet his death in 1882, only seven years after his last paper was printed, attracted little, if any, attention. The societies with which he was so closely connected published no obituary notices, and even the dates of his birth and death were unknown to those outside his own circle. After the lapse of forty-two years, this defect has been supplied by a long and interesting account of his life and work recently published in the *Mémoires* of the Dijon Academy of Sciences, of which Perrey was treasurer for nearly twenty years. A very full analysis of his work, with a complete bibliography of his writings, is contributed by M. E. Rothé, director of the central seismological office at Strasbourg. The biographical section is written by M. H. Godron, Perrey's grandson, and from this we learn that he was born on July 6, 1807, appointed lecturer in pure mathematics at the Royal College of Dijon, and professor of applied mathematics (an office created for him) in the Faculty of Sciences. In 1867, owing to ill-health, he retired, though he continued writing his seismological memoirs while at Lorient for seven or eight years longer. He died in Paris on December 29, 1882.

In reference to our note in the issue of November 8, p. 690, dealing with the origin of pearls, a correspondent writes that "about 300 B.C. Megasthenes, writing from somewhere about the middle of India, mentions the pearl fishing in the Straits of Manaar," but this is in reference to "the sea pearl called by the natives Margarita," and not to the possibility of a pearl in vegetable tissues. Megasthenes accompanied the Macedonian general, Seleucus Nicator, in his Asiatic campaigns about 307 B.C. Theophrastus (378–286 B.C.), pupil of Aristotle, but perhaps a greater master of science, specifically refers to them as coming from bivalve molluscs and as used for necklaces. Oppert translates a far earlier Assyrian inscription from Nineveh: "In the sea of the changeable winds his merchants fished for pearls; in the sea where the North Star culminates they fish for yellow amber"; pearls are also recorded as part of the tribute of the Chaldees. The Shoo King records that "the wild tribes about the Hwae brought oyster-pearls and fish" to the great Emperor Yu as tribute, 2205–2197 B.C.; these were probably pearls from freshwater mussels. Homer describes Juno as having "bright drops (τρίγκηνα) suspended from her ears," perhaps pearls, but probably golden drops. There is abundant evidence, however, of the use of pearls and pearl shell in all the ancient Eastern civilisations, and the Mahawansa records a gift of pearls and chanks (large-coiled marine molluscs found in the Gulf of Manaar) from King Wijayo (Ceylon) to his father-in-law before 500 B.C. Very beautiful are some of the beliefs about pearls, such as the concrete essence of the moon collected by the action of the negative principle in Nature (Giles's "Chinese Dictionary"), and the drops of rain falling into the open oyster shells and

concreting (Pliny), and these are equalled by the sixteenth century astrologer Cardan's theory that they are polished by being pecked and played with by doves.

THE policy of excluding Germans from international congresses is dealt with in an article in the November issue of the *Scientific Worker* by Prof. G. H. Hardy. In the course of his remarks, Prof. Hardy notes that at the International Mathematical Congress held at Toronto last summer, the representatives of the American Mathematical Society expressed their indignation at being summoned to the Congress without knowing that, according to the statutes of the International Research Council, German representatives were excluded. A resolution in favour of the removal of this ban was supported by the representatives of America, Denmark, Great Britain, Holland, Italy, Norway, Sweden, and Switzerland, but as it was contrary to the statutes it could not be carried. Unless the International Research Council itself removes the ban, the Union of Mathematics may collapse.

CAPT. KNUD RASMUSSEN, the Danish Arctic explorer, on his return to Norway from Alaska, gave some details, published in the *Times*, of his three years' journey of 20,000 miles from Greenland along the coast of North America. His object was to follow the route by which the Eskimo originally migrated westward, studying various tribes on the way. Parting from the other members of his expedition in King William land in April 1923, he met an Eskimo tribe called Netsilic, who were living completely in the Stone Age, and were in unceasing feud with tribes farther east. With some difficulty he succeeded in visiting the Netsilic settlements and gaining the confidence of the tribesmen. The exact locality of this tribe is not stated, but in this connexion Mr. Stefansson's recent discovery of the copper Eskimo in Victoria Land is of interest. Although Capt. R. Amundsen passed along much the same route in 1903–1905 as Capt. Rasmussen, the existence of white men is almost regarded as a myth by many tribes. In Alaska inland tribes of Eskimo were discovered. They have no knowledge of kayaks, but descend the rivers in large skin boats in order to buy blubber from the coast tribes. No language difficulty occurred until the Nunbaniut tribes, in the South Yukon district, were encountered. With them an interpreter had to be used owing to the wide divergence of their speech from the usual form of Eskimo. Capt. Rasmussen hoped to continue his researches in Siberia, but after crossing Bering Strait was forced to abandon the attempt owing to opposition by the Russian authorities. Large ethnographical and biological collections, as well as many cinematograph films, have been brought to Europe.

THE ship *Discovery* which is to be employed in research into whaling in South Georgia and the South Shetlands, and, incidentally, in scientific work affecting oceanography, meteorology, and magnetism, is still undergoing reconstruction at Portsmouth, and it is not likely that she will be commissioned for several months to come. If time permits, it is proposed that the *Discovery* should proceed to Stanley, Falkland Island, carrying out a programme of scientific observations on the way; and that from Stanley she should proceed to South Georgia, arriving there about the commencement of the whaling season in October 1925. Meanwhile a marine station in connexion with the expedition is being established at Grytviken, South Georgia. The building was constructed in sections in England to facilitate erection locally. Provision has also been made for a laboratory, and a considerable portion of the necessary scientific equipment has been shipped. Simultaneously with the erection of the marine station, a wireless station, and other buildings belonging to the Colonial Government, are being constructed under contract with the Marconi Company. The scientific staff at the marine station will consist of three zoologists and a hydrologist with a laboratory assistant, viz. *Zoologists*: Mr. N. A. Mackintosh (in charge), Mr. J. F. G. Wheeler, Mr. L. H. Matthews; *Hydrologist*: Mr. A. J. Clowes; *Laboratory Asst.*: Mr. A. Saunders. The officers of the expedition who have already been appointed are as follows: Scientific Officers—*Director of Research*: Dr. S. W. Kemp; *Zoologists*: Mr. A. C. Hardy, Mr. J. E. Hamilton, Mr. E. R. Gunther; *Hydrologist*: Mr. H. F. P. Herdman. Ship *Discovery* Officers—*Commanding Officer*: Lieut.-Commander J. R. Stenhouse; *Medical Officer*: Lieut.-Col. E. H. Marshall; *Chief Officer*: Mr. Ernest E. F. Letts.

PROF. P. F. FYSON, of Berhampore, Bengal, in a comment on the abridgment published in NATURE of August 30 of Prof. J. W. Gregory's presidential address to the Section of Geography of the British Association at Toronto, though agreeing that medical research has removed the old bogies of special tropical diseases, considers that in that address the effect of the unrelenting high temperature of the tropics was underrated. He believes, however, that the heat can be mitigated to a very considerable extent by the adjustment of clothing and habits. The European in India wears clothes of the same style as in his temperate home, whereas the Indian man, when not dressed to meet Europeans, wears nothing above the waist, or on legs and feet. According to Prof. Fyson, if the European is to stand tropical temperatures he must do likewise. His clothes reduce the cooling surface of the body to face and hands, and covering the rest by at least two layers of clothing interferes with the natural regulating action of the skin. He considers that women suffer more than men, chiefly because it is more difficult for them to discard undergarments. The chief reason for wearing European clothes is said to be Mrs. Grundy, who is assisted by Nature, as a hirsute white skin is not beautiful, and the white man is very sensitive to irritation by insects. Most men, even on a warm evening, wear boots or two pairs of socks at dinner to protect the ankles from mosquitoes. Prof. Fyson considers that to colonise the tropics successfully the white man, and still more the white woman, will have to throw off the idea that the naked hirsute skin is indecent, and be prepared to adopt some such dress as the Indian. They must

also, like the Indian, split each day into two, and work only in the morning and evening, resting in the middle of the day. These changes in dress and habit will only be brought about if public opinion be educated in the direction of rational dress for all occasions and for different climates. In reference to these comments, it may be remarked that Indian colleges work through the morning and afternoon without any long siesta, and though heat is doubtless the special characteristic of the tropical climate, it does not alone explain its unhealthiness, since specially hot tropical localities are often healthier than others with a lower temperature.

IN a new edition of a most important work on the textile fibres it is stated that "India is destroyed as a possible source of supply [of long staple cottons] for the English mills." This statement was rightly challenged in a review in these columns (September 20, p. 422), where it was hinted that such cottons are actually being produced in India on a considerable scale, and are eagerly bought up in Lancashire. A most important revival in the cultivation of better types of cotton is in progress in India, and, for this, great credit is due to the patient, untiring efforts of the Indian Central Cotton Committee. Hitherto, however, most of the agriculturists who have attempted the improvement of cotton strains in any part of the world have found it difficult to get their experimental products tested under mill conditions or graded on exact scientific data. The crowning achievement in India, therefore, is the foundation of a Technological Research Laboratory where this guidance may be secured to the grower. As director, the Committee has been fortunate to secure Prof. A. J. Turner, recently professor of textiles in the College of Technology, Manchester, and various Lancashire machinists have presented standard plant for an experimental mill. The foundation-stone of the Research Laboratory was laid on December 3 by the Viceroy of India, who also opened the experimental spinning mill.

A CORRESPONDENT writes in reference to the report on the "White Indians" found among the Chucunaque Indians of Panama by Mr. R. O. Marsh (*See* NATURE, Nov. 22, p. 761), to point out that this tribe had already been visited by Mr. F. A. Mitchell-Hedges and Lady Richmond Brown in the course of their expedition of 1922–1923. Mr. Marsh, on the other hand, did not reach the upper waters of the Chucunaque until the spring of 1924. Lady Brown recorded the occurrence among the Chucunaque of the albinos, whom Mr. Marsh described as "White Indians," in her book "Unknown Tribes: Uncharted Seas." It may be noted that although Lady Brown did not make a special study of the question, as did Mr. Marsh, her estimate that the albinos formed 10 per cent. of the population is identical with his. In this matter it would be difficult on either side to sustain a claim to absolute priority in view of the fact that the occurrence of white individuals in Darien was noted by the early Spanish voyager Vasco Nunez de Balboa and by the buccaneer Wafer in 1699, as well as by several later writers. Albinism is comparatively frequent among the Indians of America.

ON Friday, December 5, at the Junior Institution of Engineers, Mr. J. B. Polland gave a demonstration of metal cutting under water by the oxy-acetylene blowpipe. Mr. Polland stated that an oxidising and not merely a heating flame is used for cutting purposes. The centre of the jet of the blowpipe, therefore, consists of the actual cutting flame, while the envelope round that is more heating and yet of such a nature that its heat is dissipated more quickly in water. Round the whole of this jet is a further envelope of air which acts as an insulating medium between the flame and the water. To illustrate the fact that it is only the centre of the jet that really does the work Mr. Polland held his hand under water right in the more luminous part of the flame without ill effect. For general work the oxygen and acetylene are supplied under pressure from gas cylinders; the air or oxygen need not be pure or dry. The pressure required is determined by the depth of water at which the blow-pipe is used; the blow-pipe has been used in depths of 60 feet.

SIR JOSEPH THOMSON and Dr. W. C. Unwin have been elected honorary members of the Institution of Civil Engineers.

AN assistant chief veterinary research officer is required for Kenya. Applications for the post must be made upon a prescribed form obtainable from the Private Secretary (Appointments), Colonial Office, Downing Street, S.W.1.

THE collections illustrating stationary engines and locomotives, belonging to the Science Museum, South Kensington, are once more accessible to the public. They have been transferred from the old galleries to new accommodation on the ground floor of the eastern block of the new museum building at South Kensington (Exhibition Road).

THE Huxley Memorial Medal for 1924 of the Royal Anthropological Institute was presented to Dr. René Verneau, of Paris, at a meeting of the Institute held on November 25. Before the presentation of the medal, Dr. Verneau delivered the Huxley Memorial Lecture, for which he had chosen the title "La Race de Néanderthal et la race de Grimaldi: leur rôle dans l'humanité."

THE South African Institute for Medical Research, Johannesburg, requires a bacteriologist, preferably a medical man with special experience in plague, for research work. He must be competent to prosecute original investigations and be willing to engage in field work. Applications for the post, with references to two scientific men, should be sent to "Bacteria," c/o The Director, Lister Institute, Chelsea Gardens, S.W.1.

THE Christmas Lectures for Young People arranged by the Royal Geographical Society will be given at 3.30 on December 29 and January 2 in the Æolian Hall, 135 New Bond Street, W.1, by Major R. E. Cheesman, on "Wild Life of the Arabian Desert,"

and Dr. H. R. Mill on "Some Explorers I knew." Written applications for tickets should be made to the Chief Clerk of the Society by December 20.

APPLICATIONS are invited by the Association of Producers of Nitrate of Soda in Chile for three posts in connexion with the central research department which the Association is to organise in that country. The positions in question are a directorship of research and two sub-directorships. Candidates should be chemists or chemical engineers of first-class scientific training and experience in the investigation, design, and operation of large scale processes and plant, and, if possible, between thirty-five and forty-five years of age. Applications should be made to the Secretary, The Chilean Nitrate Committee, Friars House, New Broad Street, E.C.2.

THE twelfth annual meeting of the Indian Science Congress will be held in Benares on January 12–17. His Highness the Maharaja of Benares, Sir Prabhu Narain Singh Bahadur, has consented to be patron of the meeting, and Dr. M. O. Forster, Director of the Indian Institute of Science, Bangalore, will be president. Communications should be addressed to Prof. S. P. Agharkar, General Secretary, Indian Science Congress, 35 Ballyganj Circular Road, Calcutta. The local secretaries for the meeting are Prof. L. D. Coueslant, Department of Engineering, P.O., Benares Hindu University, and Prof. K. K. Mathur, Department of Geology, P.O., Benares Hindu University, to whom all inquiries as to accommodation should be addressed.

THE issue of part 12A of volume iv. of the *Journal de Physique et Radium* completes the volume for 1923. The part contains a description of the apparatus and experiments of a physical character exhibited at the Grand-Palais on the occasion of the jubilee of the Société Française de Physique. Although short, these descriptions are to the point and well illustrated. The complete volume has nearly 600 pages devoted to original communications, and nearly 1200 to a bibliographical review of current literature, the subject and author indexes to which occupy more than 200 pages. In future each original communication to the *Journal* is to be preceded by a summary supplied by the author, as in the *Physical Review* and the Proceedings of the Physical Society of London.

THE Report of the Natural History Society of Northumberland, Durham, and Newcastle-upon-Tyne for the year 1923–24 is a record of valuable work, in many directions, in the interests of natural history, done in a quiet and unobtrusive way, with results which are bound to be of permanent value. The Society took its share in the negotiations which have resulted in the Farne Islands being purchased and vested in the National Trust as a bird sanctuary, and it is fitting that the Museum which owed its inception to John Hancock should have been the scene of the meeting at which this important scheme was inaugurated. The Museum of the Society is undergoing rearrangement, particularly as regards the geological department, and room has at last been found to start a botanical exhibition series. It is to be hoped that the appeal, which is so earnestly and moderately made for increased support, will meet with the deserved response, for the Society has a long and distinguished record behind it, and is doing most valuable work, not only in the Museum which it supports, but also through the activities of the energetic band of naturalists which it includes amongst its members.

Our Astronomical Column.

SKJELLERUP'S AND GRIGG'S COMETS. — Messrs. Crawford and Meyer were the first to suggest the probable identity of Skjellerup's Comet 1922 I. with Grigg's Comet 1902 II. They re-examine the question carefully in Lick Obs. Bull. No. 354. They made a new determination of the orbit of 1922 I., finding a period of 5·01894 years. Perturbations by the earth were applied from March to July 1922. The elements were carried back unperturbed until July 2, 1906, and the very large perturbations by Jupiter in 1905–1906 were carefully calculated. The result is not at first sight in favour of the identity of the two comets, as it makes perihelion in 1902 several months earlier than that of Grigg's Comet. But they add that a reasonable change in the period adopted in 1922 would largely modify the great Jupiter perturbations of 1905 (minimum distance 0·08). Moreover, there were appreciable perturbations by Jupiter about 1915 that have not been applied. It is fully demonstrated that the considerable change in the inclination and other elements from 1902 to 1922 is well within the possible amount due to Jupiter. The question will probably remain unsettled until the return in 1927, which will give an accurate value of the mean motion in 1922 and permit of a more accurate carrying back.

VARIABLE STARS. — The *Japanese Journal of Astronomy and Geophysics*, 1924, No. 3, contains two papers on variable stars by Shinzo Shinjo and Toshima Araki. One deals with the correlation between period and light-range in the Cepheids and long-period variables. The light-range is shown to increase with the period, except for a slight retrogression between periods $0{\cdot}8^d$ and 4^d. The group with mean period $0{\cdot}17^d$ have a mean range of 0·70 magnitude, while the range for the group with a mean period of 500 days is more than 5 magnitudes. Moreover, on plotting the ranges and periods as ordinates and abscissæ, a definite bounding curve can be drawn (parallel to the mean curve) which includes *all* the plotted points, indicating a very intimate connexion between period and range.

The other paper is written in support of the theory that both long-period and Cepheid variability is due to revolution in an eccentric orbit of a huge meteoric swarm about a star. The systems X Ophiuchi, Mira Ceti, and 13 Ceti are examined from this point of view, and the periodic terms in the light equations of the variables are considered to be due to perturbations from third bodies (which are sometimes visible, sometimes not). The necessary eccentricity of orbit is examined; for most of the stars it lies between 0·75 and 0·92. No mention is made of the fact on the other side that the interferometer measures of Betelgeuse did not show duplicity, but appeared to indicate a variation of diameter.

Research Items.

PYGMY FLINTS FROM THE PENNINES.—A detailed account of the pygmy flint industry and sites in the Huddersfield area forms part of "Early Man in the District of Huddersfield," by Mr. James E. Patch, which is published as one of the Tolson Memorial Museum (Huddersfield) Publications. The close study of this industry which has been made by Mr. Francis Buckley shows that there is a class of pygmy flints, consisting of small and narrow-pointed tools and small narrow knives, which belong almost peculiarly to the Pennines. The best come from March Hill, where they are associated with the angle gravers and other early types of graver. A second point which emerges is that a large class of pygmy tools made from comparatively broad blades and generally not finely pointed or worked on the side is closely related to Belgian groups. It is thought that the Pennine class is developed from Upper Aurignacian, but where and how, it is not possible to say; while there is probably no Capsian influence in their source as there occur locally both pressure-flaked pygmy tools (Solutré influence) and the busked gravers (Aurignacian influence), neither of which is present in the African pygmy series. It is possible that the latter class came direct from Belgium. It is more Tardenois in type than the earlier and is not developed from it. The character and distribution of the types and sites suggests that Huddersfield and district provided temporary camping grounds for tribes and parties of men migrating to the north and west.

INDIAN CRANIA FROM SOUTH AMERICA.—In view of the scarcity of certain types of South American crania, some importance attaches to measurements published by Dr. H. ten Kate in vol. xvi. N. Sér. of the *Journal de la Société des Américanistes de Paris*. They comprise six skulls, one Carib, two Akawoi, one Arawak, and three Goajiros, also one living subject, a Lengua girl. A comparison is made with other material when available. The greatest head length is 182 mm. (Arawak); the greatest head breadth is 148 (Carib and Goajiros). The indices give the following results:—Sub-brachycephalic, Goajiros (two); hyperbrachycephalic, Carib, Akawoi (one), and Goajiros (one); mesaticephalic, Akawoi (one); sub-dolicocephalic, Arawak. One Akawoi and the three Goajiros were leptoprosopic, and the Carib and Arawak euryprosopic. One Akawoi and one Goajiro were platyrhine, the Arawak and a second Goajiro mesorhine, and the Carib, the third Goajiro, and second Akawoi leptorhine. The orbital index gave one microseme, Arawak, and the remainder megaseme. Prognathism is noted in Arawak, Akawoi, and two Goajiros. The living Lengua subject, a girl of about fifteen years, had a cranial index of 79·3, a nasal index of 86, and showed well-marked prognathism.

ABNORMAL MORPHOLOGY OF THE SHOOT OF OSMUNDA.—In the Manchester Memoirs, Vol. 68, No. 5, 1924, Prof. W. H. Lang describes some curious deviations from the normal in the development of young plants of *Osmunda regalis*, the phenomena being possibly connected with injury or with unusual conditions of cultivation in a greenhouse heated during the winter months. In addition to recording the production of shoot axes from the tip of what appears to be cylindrical green equivalents of a leaf, as well as laterally from such cylindrical rudimentary leaves or from a petiole with a lamina, Prof. Lang records a number of cases in which juvenile leaf forms pass over at their extremity into aposporously produced prothallial expansions, bearing rhizoids.

FUNGI ROTTING APPLES IN STORAGE.—As the result of the systematic examination of apples in storage during 1921–23, for the Food Investigation Board, M. N. Kidd and A. Beaumont publish in the Transactions of the British Mycological Society, vol. x., September 1924, the most complete list yet supplied of the fungi found associated with rotting apples. In examining these fungi to see whether they were responsible for the decay with which they were associated, inoculations from single spore cultures have been carried out in most cases, the method used being a new one. "Small pieces of glass tubing about 2 mm. long, previously plugged with cotton-wool, were fastened by means of luting wax to the surface of the apple, and then were partially filled with sterile liquid media and spores of the fungus sown in the liquid. By this method germination takes place under favourable conditions, and every facility is given the fungus to invade the healthy tissue."

WATER-CONTENT OF YEAST CELLS.—The November issue of the Journal of the Institute of Brewing contains a paper by N. C. Beetlestone, dealing with the actual proportion of moisture in the yeast cell. The moisture content of pressed yeast is composed of the "inherent" moisture of the cells themselves, together with the "adherent" moisture occupying the inter-cellular spaces. The total moisture is determinable readily and accurately. The yeast is mixed with water and filtered, and the specific gravity of the filtrate is measured; then a known weight of the residual yeast is treated with a definite volume of maltodextrin solution of a certain specific gravity, and by measuring the specific gravity of the liquid after filtration, it is possible to calculate the percentage of inherent moisture of the cells. The result obtained in this way varies somewhat with the age of the yeast, the extreme figures being 52·7 and 45·8 per cent., and the mean 50·8 per cent. The method is subject to various errors, but the above figures show that, under normal conditions, the yeast cell contains approximately one-half of its weight of water.

NEW SPECIES OF CHILINA.—The South American freshwater genus of molluscs, Chilina, sole representative of its family, is not so well known but that the record of additional species is noteworthy. Mr. W. B. Marshall has now been able (Proc. U.S. Nat. Mus., vol. lxvi.) to add six new species and a new subspecies to the known list. Three of these came from obscure lakes and rivers in the Andes, along the border between Chile and the Argentine; one from an undefined locality in southern Chile; Lake Nahuel Huapi, province of Rio Negros, Argentina, furnished another; whilst one was obtained many years ago, with fourteen other species of molluscs, from the stomach of a bird on Lake Wafrel, Chile.

THE GEOTHERMIC GRADIENT.—The evidence of the Polish petroleum wells on the geothermic gradient has been recently carefully tested by Dr. H. Arctowski, and discussed in his "Nouvelles Recherches sur les gradients thermiques dans les puits à pétrole de Boryslaw, Krosno et Bitków" (*Bull. Soc. polon. Natur., Kosmos*, 1924, 45 pp.). He finds that the temperature gradient varies in the wells tested from 32·3 metres per 1° C. to 41·7 metres, with a mean of 39·7 metres. This gradient is less than the mean of the European observations summarised by Prof. Daly, which he estimated as 31·7 metres per 1° C., but is near the mean of 41·8 metres of the American

wells. Dr. Arctowski remarks that the differences between the gradients of different areas in Europe are greater than between them and the American wells; and he attributes the differences to many local causes, including variations in subterranean temperature, which are due in some cases to igneous intrusions, while others, he suggests, may be the result of former climatic variations.

STRATIGRAPHY OF WESTERN AUSTRALIA.—The Journal and Proceedings of Royal Society of Western Australia, vol. ix. pt. II, 1923, includes the valuable presidential address by Mr. E. de C. Clarke on "The pre-Cambrian System of Western Australia." He classifies these rocks into five divisions, of which the oldest is the Yilgarn Series, which consists mainly of gneisses and schists. Intrusive into this are the rocks of the Kalgoorlie Series, which include mainly basic intrusive rocks. The third, the Mosquito Creek Series, occurs in the north-western part of the State, and is composed of metamorphosed sediments. It was succeeded by great intrusions of granites. The uppermost division, the Nullagine Series, consists of unaltered sediments with many basic igneous rocks. The age of this division is uncertain, and may be as late as Ordovician. The secondary sulphates and cherts of the Nullagine Series are described by Dr. E. S. Simpson, and he attributes the age of the series to somewhere between post-Huronian and pre-Carboniferous; he regards it as probably Keweenawan, the uppermost division of the pre-Cambrian. Mr. T. H. Withers had described a new Cretaceous cirripede, *Calantica ginginensis*, an interesting addition to the fauna of the Gingin Chalk.

THE USSOI LANDSLIP OF 1911.—The Pamir earthquake of February 18, 1911, was the occasion of a landslip of exceptional magnitude. A geological account of this, by J. Préobrajensky, has been published by the Comité Géologique as livraison 14 of the Matériaux pour la géologie générale et appliquée. The paper is in Russian, without an abstract in any other language, but is illustrated by photographs and maps from which, and from figures in the text, we extract the following particulars. The length of the slipped mass, across the valley, was 14,000 English feet; the width, along the valley, 17,500 ft.; and the depth, from the old ground level to the lowest point on the crest of the slip, was 1750 ft. The cubic contents of the slip are worked out as 2,219,509,670 m.^{3} and the weight as 5,992,676,109 tonnes; the ratio of the bulk of the original rock to the slipped mass is 0·816. The height through which the centre of gravity of the mass fell was 2380 ft., and the horizontal distance through which it shifted, 7350 ft. The depth of water in the lake formed by the slip was 1155 ft. on August 19, 1915, and was still rising. The mass of this slip, in round numbers 6 milliards of tons, is less than that derived by Prince Galitzin from Col. Spilko's survey, yet it places the landslip in a class by itself, for none other, of historic times, which has been measured, comes within one-fifth of its magnitude; it was surpassed, in a greater degree, by the prehistoric Flims landslip, which contains about 42 milliards of tons of rock.

ASPHALT IN PAPER MANUFACTURE.—In the September issue of the Bulletin of the Standard Oil Company, California, are given details of the application of asphalt to the manufacture of heavier varieties of paper. This is a new and interesting departure in the arts, and one destined to become of great commercial importance. Briefly, the manufacture of heavy papers, fibre boards, cartons, etc., consists in treating the original fibrous material to remove impurities, macerating the product, and pulping with water; by suitable process and subsequent drying by heat and pressure the fibrous sheets are formed. With many types of heavy paper, cardboard, and the like, the outer layers are often of better quality material than the infilling pulp, but latterly a demand has risen for a high-quality paper which shall also be water and vermin proof; this is desirable where wrappers or cartons are used for exporting fragile or perishable commodities, as in the United States. Instead of employing cheap infilling material, a layer of asphalt is substituted, or even more than one, according to requirements, such layers being intercalated between several layers of pulp film, depending on the ultimate thickness of the paper or card to be made. For this purpose fluid asphalt is mixed with a small percentage of suitable clay, water is added, and agitation set up. The resulting product is then introduced into the normal paper pulp and the whole dried; water is driven off, and the resulting sheet is richer by the inclusion of one or more layers of impermeable asphalt. The process is patented and is now being carried out on a commercial scale in California, where local resources, both of asphalt and clay, are utilised. It is claimed that not only is the paper or fibre board waterproof, but that its strength is increased approximately 20 per cent. compared with non-asphaltic board of similar thickness; also that its durability is greater than that of ordinary heavy paper or cardboard. Technically, this utilisation of asphalt is another interesting example of asphalt-water emulsion brought about by the agency of very fine and partially colloidal matter such as clay, though all types of clay known to geologists would not serve the purpose efficiently.

THE ELECTRIC ARC WITH NON-INCANDESCENT CATHODES.—In the *Zeitschrift für Physik* of October 17, Dr. A. Günther-Schulze criticises the conclusion of H. Stolt, deduced from his experiments with a rotating brass or copper cathode, that an arc without an incandescent cathode spot is possible. Only approximate calculations can be made of the temperature to be expected in a stationary cathode spot, since the conductivity and specific heat of the metal are not accurately known, but the magnitude of the spot has been found to diminish when the thermal conductivity increases, and for iron the area was $1·4 \times 10^{-4}$ cm.^{2} per ampere. Since brass has about the same thermal conductivity, the size of the spot will be about the same for that metal. The cathode fall is estimated as 15 volts, and an approximate calculation gives 2300° C. for the temperature of the spot, the actual temperature being higher owing to the formation of a film of oxide at the surface. It is also shown that when the spot moves over the surface, as in Stolt's experiment, a temperature of 2500° C. is possible. The spot was not seen by Stolt owing to the brightness of the arc, but in the mercury arc the cathode spot can easily be seen, moving swiftly over the surface, owing to the low brightness of the arc. The fact that the surface of the revolving brass cathode lost its polish confirms the author's views, since in a glow discharge a cold cathode is not attacked, even with a cathode fall of 300 volts.

AN ELECTRONIC BATTERY.—In an address delivered to the Birmingham and Midland Institute, Mr. J. B. Kramer has recently described a piece of apparatus which he has named an electronic battery. The upper surface of a plate of carbon is coated with a radioactive substance, and a plate of metal is placed above and parallel to it, with an intervening air gap. When the plates are connected to the terminals of an electrometer a difference of potential is indicated, the

terminal connected to the carbon being negative and that connected to the metal positive. The maximum potential difference was obtained with zinc. It was possible to obtain a similar, though generally smaller, effect when the two plates were of different metals. Mr. Kramer suggests that the effect is not due to α- or β-rays, but to γ-rays, which may cause a distortion or deformation of the atomic systems of the zinc and carbon atoms, thus rendering one positive and the other negative, owing to the comparative tightness of the bonds by which the electrons are coupled to the nuclei of the two elements. He considers it probable that very few, if any, of the expelled α- and β-particles reach the top plate, and that their energy and charges are spent in collisions or in recombinations.

NEW PHOTOGRAPHIC DESENSITISERS.—MM. Pathé-Cinéma (*British Journal of Photography*, p. 699) find that "basic Scarlet N," made by the Cie. Nationale des Matières Colorantes, is an excellent desensitiser and has several advantages. The weak reddish-brown tint which it imparts to the film is much more easily washed out than the intense red given by saffranine. It does not stain the skin or finger nails as saffranine does, and never produces the general chemical fog that pinacryptol is liable to do. They find also that very many dyes have an intense desensitising action when used in exceedingly weak solutions, one part in a million or even weaker, but at the same time produce a very notable degree of fog. But there are certain other dyes which, if added, get rid of the fogging power while leaving the desensitising power unaltered. As examples of these compound non-fogging desensitisers the authors give formulæ for baths containing rhoduline violet purified (Bayer), methylene blue, and rhoduline sky-blue (Bayer), to each of which pure acridine yellow is added as the protective dye. These baths are very dilute and give scarcely any or no colour to the film. Other protective dyes are auramine, benzoflavine, auracine, cachou brown, and acridine orange, and doubtless many others will be found by further investigation.

X-RAY EXAMINATION OF REAL AND CULTIVATED PEARLS.—M. A. Dauvillier, in the *C.R. Acad. Sci.*, Paris, October 27, describes his results, using Laue photographic diagrams obtained with the K-rays of rhodium and of silver and a quartz tube, with several hours' exposure and a reinforcing screen of calcium tungstate. The real pearls, as might be expected from theory, show regular rings, which are sometimes very sharp, and are due to the doublets Kα and the Kβ lines; mother-of-pearl gives more or less regular Laue figures formed of patches, which are more diffuse than those caused by crystals of calcium carbonate. The mother-of-pearl figures show a certain amount of hexagonal symmetry when the rays are perpendicular to the cleavage planes; when the rays are parallel to these planes the patches are much more numerous, and the symmetry is no longer hexagonal. Cultivated pearls show both the rings, which are due to the outer layer of real pearl, and patches due to the mother-of-pearl core. It is of course unnecessary to cut the pearl in order to make this test. The method appears to be suitable for detecting imitations of other kinds.

THE β-RAY SPECTRUM OF THORIUM B + C.—Dr. W. Pohlmeyer describes an investigation, using the ionisation method, in the *Zeitschrift für Physik* of Oct. 10. The dimensions of the chamber K, in which the rays were magnetically deflected, were large enough to minimise the effect of the secondary rays produced on the walls, which were lined with cardboard to reduce further this effect. A wire coated with thorium-B in equilibrium with its products of disintegration, thorium-C + C′ + C″, was placed 1 cm. above, and parallel to, a slit S_1, of dimensions 3×10 mm., in a lead plate forming the top of K; β-rays of a certain velocity were bent in circles through a large stop by the magnetic field, and were thus focussed on a second slit S_2 at the top of K, and passed into the ionisation chamber through a thin air-tight partition. The ionisation chamber was protected from the direct effect of the preparation by lead blocks. The field was varied step by step, and the ionisation measured for each step. Several lines of thorium-B and of thorium-C + C″ were observed in the resulting curve, and the influence of some of the weaker lines was clearly shown. The spectrum was shown to be limited on the high-velocity side, confirming the results of Baeyer, Hahn, and Meitner. The intensity of the two strongest thorium-B lines is large compared with the continuous background. The experiments, and a discussion of the conditions, show that this background is to be ascribed to secondary influences, including the broadening of the numerous lines obtained in the photographic spectrum, owing to the necessarily large width of the slit S_1 and the preparation wire. Its existence does not invalidate the assumption that the primary β-rays leave the nucleus with a definite velocity.

EFFECT OF PRESSURE ON ORGANIC SUBSTANCES.—The dependence on pressure of the adiabatic cooling of some organic substances in the liquid state has been investigated by N. A. Pushin and E. V. Grebenshchikov (J. Chem. Soc., Oct.). The results show that phenol changes to a denser modification under a pressure of 2250 kg./cm.^{2} and at a temperature of 64·4°. Of all the substances investigated (alcohol, urethane, glycerol, castor oil, etc.), the greatest coefficient of adiabatic cooling (dt/dp) was shown by benzene; the coefficient decreases with increasing pressure in all cases. Some *p*-toluidine and phenol mixtures were also investigated; the results point to the formation of *p*-toluidine phenolate.

STERIC HINDRANCE AND COMPLEX RING COMPOUNDS.—It is well known that a chemical action is often profoundly modified by the presence of groups which exert a definite influence in promoting or in hindering its normal course. No entirely satisfactory solution of the problem will be possible until more abundant experimental data are available. A useful contribution to this subject has been made in vol. 18, No. 2, of *Fortschritte der Chemie, Physik und physikalische Chemie*, "Über die Bildung von Chinon-imiden und Phenoxazonen aus o-Amino-phenolen." Nach Versuchen von E. Mürbe, K. Saurwein, G. Deines und J. Schornstein (Berlin: Gebrüder Borntraeger, 1923, 3*s*.), by K. von Auwers, who with the help of four collaborators has studied the oxidation of derivatives of o-aminophenol. Full details are given of the preparation and oxidation or attempted oxidation of these compounds, and after a critical survey of the results the author has drawn the conclusion that steric hindrance is responsible for any deviation from the normal reaction, which is as follows: an orthoaminophenol is first oxidised by hydrogen peroxide or by air in alkaline solution to a bimolecular quinoneimide, which then condenses further to a phenoxazone. The action may, however, be arrested at the first stage or even entirely inhibited by the presence of certain substituents. The influence of halogen atoms and of the following groups, namely, CH_3, NO_2, CN, COOH and COOEt, in different positions, has been carefully studied and the results are classified.

New Chemistry Department, University of Edinburgh.

THE Chemical Laboratories, the foundation stone of which was laid by the King on July 6, 1920, were formally opened by the Prince of Wales on December 3. The University had resolved in 1913 to build a new chemistry department, and detailed plans were drawn up for its construction, but the outbreak of war led to the postponement of the scheme. Early in 1919 the matter became of immediate urgency, as it had by that time become evident that large numbers of ex-service men were about to enter on university courses in pure and applied science, as well as in medicine. The University met the situation by resolving first to appoint a professor of chemistry in relation to medicine, who would be accommodated in the old laboratories, and second, to erect a new chemistry department on a site affording greater facilities for adaptation and extension than the site originally contemplated.

FIG. 1.—The King's Buildings, University of Edinburgh (Chemistry Department).

The University accordingly purchased some farm land on the southern outskirts of the city, about a mile and a half from the Old College. This land, of 115 acres in extent, is intended to provide sites for all the scientific departments of the University, which will, as necessity determines and as money becomes available, move out to the King's Buildings, the new group being so named with His Majesty's permission.

The Chemistry Building (Fig. 1), excavation for which was begun in November 1919, has a frontage of 220 feet and a depth of 320 feet. It was constructed by Mr. A. F. Balfour Paul, architect, on sketch plans submitted by the professor of chemistry, Sir James Walker. The front block is of two storeys; the remainder is of one storey only, with the exception of a small section to the south-east which has a basement for an engineer's house, cloak-rooms, etc. In this basement is a separate entrance for elementary students. The construction is mainly of brick relieved by stonework on the frontage, which faces due north. The whole building is fireproof, floors and roofs being of reinforced hollow tile.

The general lay-out is indicated by Fig. 2. Three parallel corridors running north and south meet at one end the east and west corridor of the front block, and at the other end are free for extension. Between the central and side corridors are the main laboratories and lecture rooms with their subsidiary offices and service rooms. These are all lit on the factory shed principle by a saw-tooth roof, glazed with north slope window-lights. On the outer face of each side corridor is a range of rooms lit by large windows in the walls. These serve as balance-rooms, etc., for the main laboratories, and as research rooms. On the ground floor of the front block are the physico-chemical laboratories, dark-rooms, and special rooms for gas-analysis, etc.; on the upper floor are the library, administrative rooms, staff common-room, research rooms, and laboratories destined for crystallography, X-ray work, and the like.

The main laboratories are four in number, each 45×70 feet internal measurement. They are fitted with benches to accommodate $72 \times 4 = 288$ students in the elementary laboratory, $72 \times 2 = 144$ students in the laboratory of the second year, 48 students in the advanced inorganic laboratory, and 40 students in the advanced organic laboratory. The physico-chemical rooms can provide working places for about 30 students. Thus the department could take more than 260 students working simultaneously, and has a bench capacity for 550 students. In the special research rooms at present equipped, accommodation can be found for 25 post-graduate workers, a number

capable of being doubled when all the rooms are completed.

A section of the department is devoted to technical chemistry, the object being to familiarise students in a general way with technical plant and processes. There are three small general working laboratories, two research rooms, and a workshop, with office, stores, etc. The equipment is for the most part of a mobile type, the main rooms being fitted on the walls with service pipes for water, gas, steam, electric light and power, compressed air and vacuum, to which small-scale plant can be connected. From 15 to 20 students can simultaneously receive instruction in this section.

There are four lecture rooms, two large (seating capacity 160) and two small (seating capacity 100 and 70 respectively). These are lit by cupolas and three of them can be darkened by lowering a false ceiling operated electrically. The four lecture rooms are served by a single preparation room, adjoining which is a commodious lecture museum.

The heating of the department is effected by means of low-pressure steam, and the ventilation is by extraction, the main inlet duct being under the central corridor, and all air being admitted to rooms over steam pipes or radiators. Each main laboratory is served by an independent fan connected with draught-holes on the students' benches, a scavenging fan being also provided at a high level. The draught-cupboards of the department are connected with two special high-power fans. Each pair of lecture rooms has a fan which runs normally at a low speed, but is capable of changing the air of the room completely in a few minutes between lectures. The air is admitted under the lecture bench and extracted through two sets of apertures in the back wall of the lecture room, one set at head level and the other near the roof.

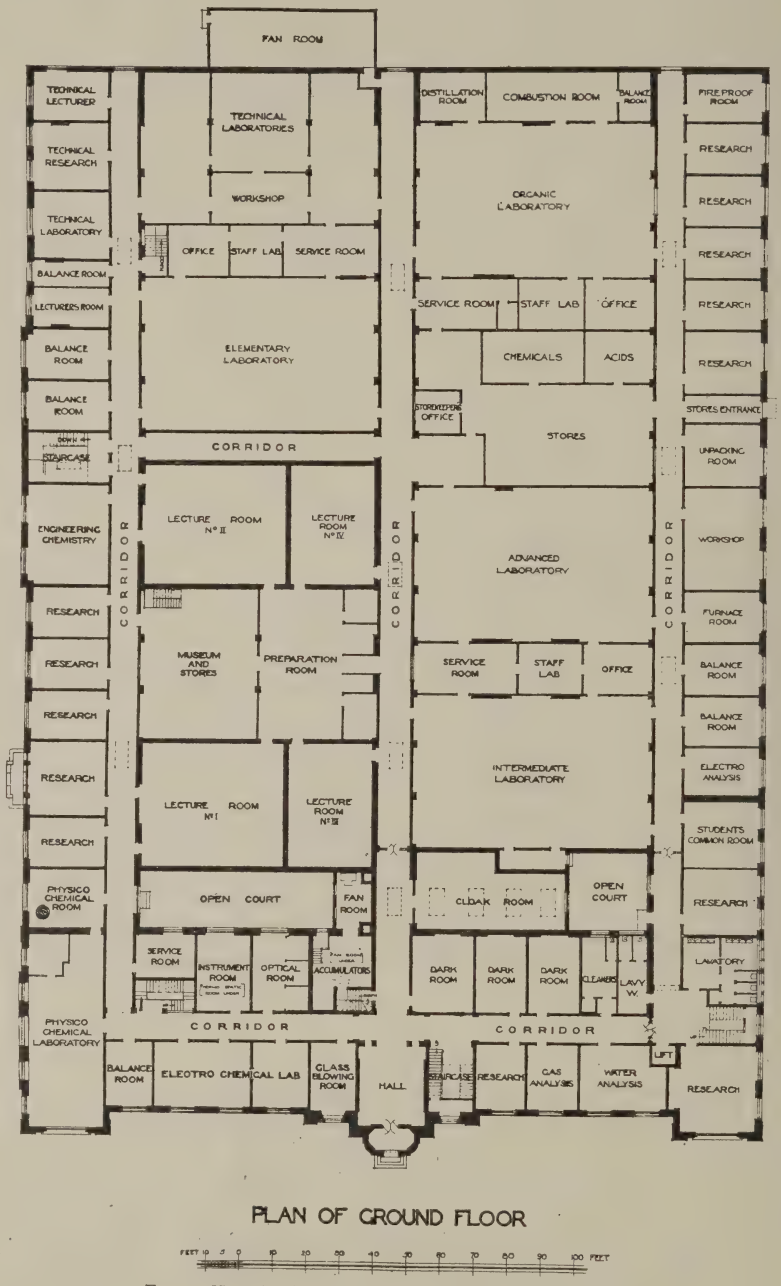

FIG. 2.—New Chemical Laboratories, University of Edinburgh.

Electricity is supplied from the city at 230 volts A.C. and 460 volts D.C. for power. A large motor generator yields direct current at 100 volts for wall plugs, and for charging accumulators, of which there are two sets of 20 cells each—one for electro-analytic and electro-synthetic work, the other for physico-chemical work.

The first section of the department was fully occupied in October 1921, the second in October 1922, and the third and final section in October 1924. The actual cost of the buildings, inclusive of scientific equipment and all other charges, has been somewhat less than 200,000*l*.

At a luncheon following the admission of the Prince to the honorary LL.D. degree, the Principal announced that the deficit of 88,000*l*. on capital incurred since the War had in the preceding few days been met to the extent of 75,000*l*. by subscriptions, including a donation of 50,000*l*. from Sir Alexander Grant.

The Adelaide Meeting of the Australasian Association.

THE seventeenth meeting of the Australasian Association for the Advancement of Science was held in Adelaide, South Australia, on August 25–30 inclusive.

The number of members who attended the meeting is estimated at 750, and delegates from all the important scientific institutions and societies in Australia and New Zealand were present. The delegates who attended exceeded 100 in number, and these represented at least fifty institutions, including the Australian National Research Council, the New Zealand Institute, the various State Royal Societies, the various universities both of the Commonwealth and of New Zealand, the Federal and State Government Departments, the British Medical Association, the various mining, engineering, and chemical institutes, together with kindred institutions.

The retiring president, Sir George Knibbs, inducted the president for 1924–26, Sir John Monash, on the evening of August 25. The president's inaugural address on "Power Development" attracted widespread attention throughout Australia and New Zealand.

Prof. G. Elliot Smith, of University College, London, attended the meeting, and assisted Section F (Anthropology) in urging the Federal Government to found an Australian chair of anthropology at the University of Sydney. The Association also supported a resolution of the Australian Universities' Conference to establish a chair of forestry at the University of Adelaide.

The presidential addresses to Sections included the following: A (Astronomy, Mathematics, and Physics), Prof. D. M. Y. Sommerville, "The Development of the Ideas of Space and Time"; B (Chemistry), Prof. A. C. D. Rivett, "National Research"; B (Subsection Pharmacy), Mr. E. F. Gryst, "Pharmaceutical Progress"; C (Geology and Mineralogy), Dr. H. C. Richards, "Volcanic Activity in Queensland"; D (Zoology), Prof. W. E. Agar, "Some Problems of Evolution and Genetics"; E (Geography and History), Capt. J. K. Davis, "Sailing Directions"; F (Ethnology and Anthropology), Mr. H. D. Skinner, "Origin and Relationships of the Material Culture and Decorative Art of the Maoris of New Zealand"; G (Social and Statistical Science), Prof. D. B. Copland, "Monetary Policy and its Reaction upon Australia"; H (Engineering and Architecture), Prof. H. E. Whitfeld, "Efficiency in Modern Life"; I (Sanitary Science and Hygiene), Dr. J. S. Purdy, "Vitamines and Fruit in Diet"; J (Mental Science and Education), Mr. J. Nangle, "Vocational Guidance"; K (Agriculture and Forestry), Prof. R. D. Watt, "The World's Food Supply"; L (Veterinary Science), Dr. S. Dodd, "Cancer in Domesticated Animals"; M (Botany), Mr. L. Rodway, "Ecologic Conditions of Vegetation in Tasmania."

A general statement was made by the permanent honorary secretary regarding the pressing needs of the Association, inasmuch as it is coming to be seen that science in Australia and New Zealand needs to extend its usefulness, especially in view of the impetus given to the study of Pacific problems by the recent Pan-Pacific Science Congress, and the Food Conservation Congress, held in Australia and Honolulu respectively. This could be accomplished by the Australasian Association acting as co-ordinator of, and spokesman for, the various divergent interests of scientific and technical societies. In other words, the best work could be done apparently by an affiliation of all the scientific institutions with the Australasian Association for the Advancement of Science, and with the hearty co-operation also of the Australian National Research Council and the New Zealand Institute.

The present machinery of the Australasian Association is too cumbrous for this purpose, and it is found necessary to take a central office in Sydney with an officer in permanent attendance to assist the permanent honorary secretary.

A constitution of few articles is needed with flexible by-laws or regulations to each of the main articles. Continuity of membership is needed, and some permanency also for secretaries of Sections, whereby recommendations to Governments and other authorities might be well considered before presentation.

Perth, Western Australia, was selected as the place of the eighteenth meeting of the Association, the date chosen being August 1926. The president for this meeting will be Sir Thomas R. Lyle. The Government of Western Australia has promised 1200*l.*, mainly towards defraying the cost of the publication of the Proceedings.

The nineteenth meeting will be held at Hobart, Tasmania, in January 1928, with the promise of financial support from the Tasmanian Government.

E. C. ANDREWS.

Preservatives in Food.[1]

THE report before us contains an account of the preservatives and colouring matters found in different articles of food, together with the Committee's opinion upon the nature and quantities of these substances which should be permissible, taking into consideration, on one hand, their effect upon the body, and on the other, their efficiency in preserving, or making attractive, the different articles of diet in which they are found. Apart from the main body of the report, a series of appendices gives the names of the witnesses examined, and excerpts from the laws of other countries on the use of preservatives and colouring matters in foods, with details as to those which are permissible and which prohibited: one other appendix will be referred to in more detail below.

The principles which guided the Committee in the interim report on the use of preservatives in meat, which have already been noticed in these columns (NATURE, September 20, p. 448), are emphasised again in the report under consideration. Since the ideal of the consumption of fresh food alone is impracticable of attainment under modern conditions of civilisation, and cold transport or sterilisation by heat may be unsuitable processes in certain cases, the only course open is to use some preservative, and the Committee has devoted considerable attention to the question as to which preservatives are the least likely to be harmful to the individuals consuming them in small quantities, although often over long periods of time, and yet are reasonably efficient in preventing decomposition or other change in the food or drink product. In certain cases, preservatives have a further disadvantage in that their addition may give a sense of false security and encourage slackness in the preparation of the food: in other cases their use seems to have become a habit

[1] Ministry of Health. Final Report of the Departmental Committee on the Use of Preservatives and Colouring Matters in Food. Pp. 84. (London: H.M. Stationery Office, 1924.) 1s. 6*d.* net.

with some of the manufacturers of certain articles of food, such as pickles, since others do not use them at all.

The report considers first the different substances which have been used as preservatives and their effect upon the human economy; they can be divided into three groups. In the first are hydrofluoric acid, its salts and derivatives (seldom if ever used at the present time), and formaldehyde and its derivatives. The effects of the latter have been already mentioned in the account of the Committee's Interim Report and will not be further considered here. It is sufficient to state that in the opinion of the Committee, with which we are in complete agreement, the substances in this group should be completely prohibited in articles of diet. In the second group are placed boron preservatives and salicylic acid and its salts: these should also be prohibited. Although this conclusion may cause some surprise, the evidence in favour of it is remarkably strong. In the first place, both boric and salicylic acids act as irritants to the alimentary tract; the former, moreover, is only excreted slowly after absorption, so that its action is cumulative. Boric acid or its salts are used at present very largely in cream, butter, liquid eggs, margarine, and potted meats, or dusted over bacon and hams exported to Great Britain: but since these products are frequently sold without the addition of preservatives, it appears quite possible to dispense with them, providing methods of preparation and conditions of transport are satisfactory. This conclusion is strengthened by the fact that at the present day the milk supply is satisfactorily maintained although the addition of preservatives is forbidden, a state of affairs which, twenty-five years ago, was considered to be impossible of achievement in some quarters. As regards salicylic acid, which is used chiefly in beverages, benzoic acid has about the same effectiveness as a preservative and is less irritant to the stomach, and is therefore preferable.

The third group comprises the least harmful of the preservatives in benzoic acid, sulphurous acid, and their salts: the report gives a list of the foods and beverages in which they may be permitted, together with the maximum amounts allowable. Sulphur dioxide may be permitted in sausages, jam, dried and preserved fruits, beer and cider, and wines, cordials, and fruit juices, in amounts of a few grains per pound or pint. Benzoic acid should be allowed only in the following beverages: coffee extract, non-alcoholic wines and cordials, and sweetened mineral waters and ginger-beer.

Turning to the question of colouring matters, the Committee advises the prohibition of the use of copper sulphate as an agent for preserving the colour of green vegetables. They consider that this will not affect the sale of canned vegetables, seeing that peas canned without the use of copper find a ready sale in Great Britain. As regards other colouring matters, a few pigments containing iron and some natural organic colours such as gamboge, saffron, caramel, and cochineal are considered harmless: but of the synthetic aniline dyes, relatively few have been considered harmless in other countries, and the Committee recommends that a list of those permitted should be drawn up by the Minister of Health: this is necessary, since many of these dyes are potent antiseptics in dilute solutions; moreover, they cannot be grouped in classes, since a harmful product may be closely related to one that is quite innocuous.

Finally, the report considers the best method of making its conclusions effective: among its recommendations here is one that the amount of preservative or nature of colouring matter permitted should be definitely laid down by law, and another that the processes of preparation of food for human consumption should be under closer control. In this connexion, improved methods and facilities of transport and storage are urgently required. In one of the appendices is given an interesting example of the co-operation of a trade in reducing the amount of preservative present in a food, by its members agreeing not to use the article containing it in certain types of foodstuffs prepared by them. The report should do much to raise the standard of preparation of food in Great Britain.

Works of Early Man in East Anglia.

AT the autumn meeting of the Prehistoric Society of East Anglia, held at the rooms of the Geological Society, Burlington House, London, on November 12, Mr. R. A. Smith, and afterwards the president, Mr. Henry Balfour, in the chair, special reference was made to the loss sustained through the death of the late Mr. E. T. Lingwood, of Westleton, who, in addition to great abilities and enthusiasm as a practical excavator and collector of flint implements, had for years done very valuable voluntary work by drawing large numbers of the specimens selected for illustration in the annual Proceedings of the Society. Had Mr. Lingwood lived, a proposal to offer him honorary membership of the Society would have been brought forward at the next annual meeting, and it was unanimously resolved by the London meeting that this distinction should be offered to Mrs. Lingwood, together with an expression of the sympathy of the members of the Society.

An important announcement concerning the protection of Grime's Graves, Norfolk, as a national monument was made by the hon. secretary, Mr. G. Maynard, of the Ipswich Museum, who stated that H.M. Office of Works has accepted a suggestion made on behalf of the Society and has taken steps to include in the schedule a considerable area of the open warren which borders the well-known group of ancient flint mines on the Weeting Hall estate. The additional area includes the sites of the recently discovered pits on the slopes of the Grime's Graves ridge which are being investigated by Mr. A. L. Armstrong.

It was also announced that with the approval of the Office of Works, the owner of the estate has given permission for the erection of a shelter over the mouth of the pit cleared out by the Society in 1914 and subsequent years. This protection is designed to prevent the silting up of the entrance to the galleries at the bottom of the pit, and to facilitate entrance to the old mine workings. The delimitation of a footpath across the warren to the site has also been agreed to. Information as to the probable cost of the shelter is being obtained, and the council of the Society is shortly to be asked to consider the question of taking up the scheme.

Mr. J. P. T. Burchell described some stratified finds on the North Kent coast, where the peculiar elongated flint implement known from its abundance in the bed of the Thames as the "Thames pick," is found in plenty at the foot of the cliffs but is without a definite geological horizon. The cliffs examined are at Bishopstone near Reculver, and Hampton near Herne Bay. At the former site, hand-axes of Chelles and St. Acheul type have been found in the ochreous gravel which is capped by brick earth, with Neolithic flakes and cores in its upper levels.

Sunk in the top of the brick earth and adjoining

a shell-heap with Early Iron Age pottery, a hearth has been found containing flint flakes and a small circular implement. An interesting discovery is that an undisturbed stratum of gravel, 5 inches deep, seals in the Iron Age hearth and midden; and above this is 1½ feet to 4 feet of loam with flints and more pottery and burnt flints to the surface. As the Thames pick can scarcely belong to the Iron Age and is probably later than the drift, the only course is to refer it to the lower part of the brick earth.

Mr. W. H. Cook reported on the discovery of a flint implement working-site of late St. Acheul or early Le Moustier date in the Medway valley. Several thousands of flint artifacts were found lying in heaps covered by brick earth and apparently undisturbed since the mid-Pleistocene period. Excavations in the chalk near Frindsbury opposite Rochester have revealed a chalk slope more than half a mile in length leading down to the alluvial plain of the Medway. On the chalk slope are a series of gravels and brick earths resting at various levels on well-defined platforms or terraces. At 90 feet above the river level and corresponding to the 100-foot terrace of the Thames and Somme are the beds of the ancient Medway, which are of the same Chellean-Le Moustier age. The recent discovery was made in a shallow deposit of dark clayey brick earth probably representing the alluvia of the ancient 100-foot terrace river, as it occurs on the upper limits of the terrace and lies in a hollow of an ancient calcareous surface loam which is clearly older than the terrace deposits. In addition to palæolithic hand-axes, scrapers and grattoir, hammerstones, masses of flint flakes and numbers of massive core pieces were found. None of the cores were, however, of the tortoise-backed type. An accumulation of coarse sub-angular fragments of chalk, apparently equivalent to the well-known Coombe rock of Northfleet, etc., was found at the junction of the chalk with the drift beds at various levels, but it is clearly of later age than the 100-foot terrace.

Dr. Cyril Fox, of Cambridge, dealt with evidence of continuity of occupation of a site known as Bellhus, at Abington Pigotts, Cambridge, from Early Iron Age down to late Medieval times. The settlement had probably been founded in La Tene I. times (400–250 B.C.), possibly as a result of the general tendency elsewhere exemplified during this Age for migration to take place from the pasture-land to the more fertile districts bordering the alluvium, and thus connected with the early development of corn growing. The evolution of the pottery forms during the Early Iron Age was discussed and many examples shown. The abundance of 1st century A.D. finds seems to show that no serious setback in prosperity accompanied the Roman conquest and the story of the settlement only became obscure after A.D. 390. Certain pottery forms, particularly the Roman mortarium, seem to show an evolution into types which can be clearly distinguished as Early Saxon.

Mr. A. L. Armstrong reported upon the past season's work at Grime's Graves, Norfolk. The continuance of last year's excavations has shown that the simple shaft-pits discovered on the outer slopes of the site are placed close together in rows. The extremely compact nature of the filling and absence of surface indications were again noted, as well as the absence of galleries and deer horn picks. The work appears to have been done with short hand-picks of bone. Excavation of a large hearth in one of the old shaft hollows on the higher ground has yielded several examples of pottery now dated as Hallstatt, Early Iron Age.

University and Educational Intelligence.

EDINBURGH.—The Prince of Wales visited the University on December 3, for the purpose of opening the new Department of Chemistry, King's Buildings, which has recently been completed at a cost of about 200,000*l*. Immediately afterwards, at a special graduation ceremony in the M'Ewan Hall, the Chancellor of the University, Earl Balfour, conferred on His Royal Highness the honorary degree of LL.D. At the subsequent luncheon, the Principal announced that Sir Alexander Grant had given 50,000*l*., that the Carnegie Trust was likely to add 15,000*l*., and gifts from other sources amounted to 10,000*l*., which, he stated, would bring relief, encouragement, and hope to those who administer the affairs of the University, though the University's need remained yet so great that he trusted there was a larger harvest to follow.

To commemorate the hundredth anniversary of the foundation of the Royal (Dick) Veterinary College, a Centenary Post-graduate Fellowship has been instituted. A Fellowship Fund has been established, and a deed has recently been signed by which trustees have been appointed to administer the Fund. The aim of the Fellowship is the assistance of promising graduates who may wish to pursue further study and research, and it is hoped that in this way the advancement of veterinary science may be promoted. The amount of the Fund is at present 5802*l*., but the trustees feel confident that additional contributions may be expected from those who benefit from the discoveries of veterinary science, as applied to animal husbandry and public health.

LEEDS.—Applications are invited for two posts, namely, an assistant lectureship in agricultural botany and a demonstratorship in the same subject. Particulars may be obtained from the registrar, to whom applications for the posts should be sent by, at latest, December 22.

LONDON.—The following doctorates have been conferred:—*Ph.D.* (*Science*): Miss M. A. C. Boas (Lister Institute of Preventive Medicine) for a thesis entitled "Part I. A Method for estimating Calcium and Phosphorus Retention in young growing Rats; Part II. The effect of Green Food in the Diet on the Calcium and Phosphorus Metabolism of Rats as compared with that of Cod Liver Oil"; Amar Nath Puri (Rothamsted Experimental Station) for a thesis entitled "Soil Colloids—A Study of Phenomena relating to Surface Forces in Soil"; Mr. H. Gregory (Imperial College—Royal College of Science) for a thesis entitled "Experimental Determination of the Thermal Conductivities of Gases," and other papers; Mr. E. Spencer (Imperial College—Royal College of Science and University of Liverpool) for a thesis entitled "Investigations of Problems connected with the formation of Authigenous Minerals in Clays, Coals, and Limestones from India and elsewhere"; Mr. Murray Stuart, for a thesis entitled "The Potash and Rock Salt Deposits of the Punjab and Kohat"; Mr. G. F. J. Temple (Birkbeck College) for a thesis entitled "Researches in Whitehead's Theory of Relativity," and another paper; Mr. H. G. Turley (Battersea Polytechnic) for a thesis entitled "Experiments on the Walden Inversion. The α-Hydroxy Acids and their Derivatives with special reference to Lactic Acid." *Ph.D.* (*Engineering*): Mr. G. F. Dutton (Imperial College—City and Guilds College) for a thesis entitled "Some Acoustic Properties of Telephones."

Applications are invited for the Keddey Fletcher-Warr studentships for the promotion of post-

graduate research. The studentships are tenable normally for three years, and are of the annual value of not less than 200*l*. They are open to men and women of European descent who are graduates of a British university or of similar standing, preference being given to a graduate of the University of London. Further particulars are obtainable from the Academic Registrar, University of London, South Kensington, S.W.7. The latest date for the receipt of applications is January 31.

THE Faraday House Electrical Engineering College, Southampton Row, W.C.1, has an opening for an assistant lecturer in mathematics and physics or chemistry. Preference will be given to an engineering graduate. Written applications should be sent to Dr. A. Russell, at the College.

THE University College of the South-west of England, Exeter, has sent us a copy of the annual reports of its Council and Senate for 1923–24. The Council has co-operated with the Plymouth Education Authority in planning an extension of the work of the College to Plymouth. A scheme has been framed for the institution of degree and diploma courses in engineering (civil, electrical, marine, and mechanical) and in commerce, to be conducted in Plymouth, and for the extension of the law teaching and extra-mural work now carried on there by the College. Pending the maturing of the scheme and the provision of the requisite funds, the College Council will be represented on a sub-committee constituted for the purpose of advising the Plymouth Education Committee on the administration of the Plymouth Technical Schools, and the Principal of the College will give part of his time to acting as supervisor in these schools.

THE New York correspondent of the *Times* records that Mr. George Eastman, founder of the Eastman Kodak Company, who has already given away half his holdings of stock in that concern, has made gifts of the remaining half to several institutions of learning. At the lowest estimate this half is worth about 3,000,000*l*. Of this amount, about 1,700,000*l*. will go to the University of Rochester, and about 900,000*l*. to the Massachusetts Institute of Technology. This will bring the total of Mr. Eastman's gifts to the latter institution up to 3,000,000*l*. The remaining money, about 400,000*l*., will go to the Tuskegee Institute, the Hampton Institute, and the Southern Schools for the Education of Negroes, but these gifts are contingent on gifts of a like total from others.

THE annual statement for 1923–1924, of the Rhodes Scholarships, has recently been issued by the Rhodes Trust, Seymour House, Waterloo Place, London, S.W.1. The number of scholars in residence during the year was 220, of whom 109 were from the British Empire and 111 from the United States. Grouping the scholars according to their studies, it appears that mathematics claimed 60 and natural science and medicine 57, while education, forestry and agriculture, and anthropology claimed 4, 2 and 1 respectively. The present academic year opened with 180 scholars in residence. Information about Rhodes Scholarships may be obtained on application to the offices of the Trust. In the United States application may be made to President Aydelotte, Swarthmore College, Swarthmore, Pennsylvania; in Canada to Mr. J. M. Macdonnell, National Trust Company, Ltd., Montreal, P.Q.; in Australia to Mr. J. C. V. Behan, Trinity College, Parkville, Victoria; in South Africa to Mr. P. T. Lewis, South African Chambers, St. George's Street, Cape Town.

Early Science at the Royal Society.

December 14, 1664. The experiment mentioned by Monsieur Huygens of making a thermometer with a cane of salt-water and a glass-ball poised in it, was tried; and it was found that the glass-ball rose and subsided, according to the alterations of heat and cold. It was ordered, that it be kept and compared with the other thermometers, in order to see whether it be so nice and sensible as they.—There was read a paper sent from Oxford by Mr. Boyle to the secretary, containing certain proposals of Mr. Austen, about the planting of fruit and timber-trees which Mr. Austen desired might be recommended to the parliament. It was referred to the committee for agriculture.

December 16, 1663. Mr. Waterhouse gave notice of a letter received by him from Mr. Children, signifying, that the thermometer sent to him was broken: as also, that he would shortly communicate his manuscripts of observations of the weather, and first of all those of three several persons made upon every day of the year 1648.—Mr. Hooke proposed an experiment to be made with the compressing engine, of applying a gun to it, to see with what force it will be able to shoot a bullet, arrow, etc. The operator was ordered to prepare a gun for this purpose.

December 17, 1668. At this meeting were present two Italian gentlemen, the Marquis Ricardi, and Signor Seoni, both introduced by Count Umbaldino. They acquainted the society of the singular respect, which the Cardinal Leopold de Medicis had for them, and that he desired to have his excuse made for not having himself returned his acknowledgments for the "History of the Society" [Sprat's] sent to him, which he had been hindered from doing by his lately received dignity of Cardinal; but that since that time he had desired and already obtained the Pope's permission to correspond with the society, of which he now intended to make use, to let them see the esteem, which he had of them and their institution.—The president thanked these gentlemen for acquainting the society with so favourable an inclination of his Eminence to them, and that they would study to entertain so noble and promising a correspondence with all reciprocal services.

December 18, 1679. Mr. Henshaw read a paper, which he had from Dr. Plot, copied from the Records in the Tower, containing an account of the strange recovery of certain persons a long time after their having been executed.

December 19, 1666. It was ordered that at the next meeting the experiment be made of transfusing the blood of a sound dog into a mangy one; and that the operator provide necessaries for it, to begin the operation about twelve o'clock that day. Mr. Boyle suggested that it might be considered to make an estimate of what proportion of blood is let out. Dr. Pope moved, that a trial might be made of letting out half the blood of a dog, and of supplying it with warm milk, or, because milk may coagulate, with a liquid of barley-cream. Mr. Boyle mentioned, that not only care must be had of the kind of liquor to be injected, but also of the manner and place of the injection; in default whereof the liquor would drive the blood before it to the heart and by too great abundance crowding in there kill the animal. To avoid which, it might be injected by degrees, and in the remoter parts from the heart, as in a crural vein.

1667. Mr. Coga being introduced gave an account of the effects of the experiment of transfusion repeated upon him, viz., that he found himself very well at present, though he had been at first somewhat feverish upon it; which was imputed to his excess in drinking too much wine soon after the operation.

Societies and Academies.

LONDON.

Royal Society, December 4.—A. **Fowler**: The structure of the spectrum of ionised nitrogen. New observations of the second line spectrum of nitrogen (N II or N^+) have been made in the region λ6650 to λ2200, and 52 lines have been classified. In this region, all the terms which have been identified belong to singlet or triplet systems. These have been found to combine with each other in agreement with the selection rules which are applicable to other spectra in which p' and d' terms appear. The absolute values of the terms cannot yet be stated, but a value of 70,000 has been provisionally assigned to $2p$, in accordance with the value suggested for $1p$ by astrophysical data. The largest term identified is a p term, and it may be inferred that the series electron in singly ionised nitrogen normally occupies a 2_2 orbit, so that the atom of N II has two electrons in 1_1 orbits, two in 2_1 and two in 2_2 orbits. It is also the probable arrangement of orbits in the neutral atom of carbon, the spectrum of which has not yet been resolved into series. Three groups of lines which involve one of the p terms are remarkable as showing large displacements (> 0·5 A) to the red in vacuum tubes containing nitrogen at relatively high pressures.—H. **Jeffreys**: On the formation of water waves by wind. The wind presses more strongly on the slopes of the waves facing it than on the sheltered slopes, and when the resulting tendency of the waves to grow is just able to overcome viscosity, waves are first formed. A numerical constant in the theory can be adjusted to make the wind velocity required to produce waves agree with observation; and when this is done the predicted wave-length of the waves first formed agrees with observation without further assumption. To account for the skin friction of the wind over the seas as the resultant drag due to the horizontal thrust of the wind on the exposed sides of the waves, wave velocity must be about three-quarters of the wind velocity, which is in accordance with observation. The formation of waves with such a velocity, however, appears to require values of the eddy-viscosity much smaller than are indicated by observations of ocean currents.—J. E. **Jones**: (1) On the determination of molecular fields. III. From crystal measurements and kinetic theory data. With the information obtained about argon in earlier papers from its properties as a gas, theoretical calculations are made of the interatomic distances to be expected in argon as a crystal. Crystalline argon has recently been obtained, and its structure measured and examined, and it is thus possible to fix the molecular field of argon. Theoretical calculations are also made of interatomic distances in potassium chloride and calcium sulphide which are in good agreement with observations. (2) On the atomic fields of helium and neon. The atomic field of helium is determined from measurements on its isotherms and viscosity, that of neon from measurements of its viscosity, and heat conduction and the crystal constants of sodium fluoride and magnesium oxide.—F. S. **Tritton**: A centrifugal method of making small pots of electrically fused refractory materials. A method is described of making small pots of refractory materials (magnesia, alumina, zirconia, and tungsten metal) by electric arc fusion combined with centrifugal action. The material, shrunk by previous fusion and finely powdered, is placed in a silica cup and a deep central depression is made in the powder. Two graphite electrodes fit closely into this depression. In the case of alumina or zirconia, in order to prevent the formation of carbides, a stream of oxygen is blown between the electrodes and the refractories during fusion. Pots of fused magnesia made in this way have been successfully used for holding molten iron oxide, which penetrates all other known refractories.—J. W. **Nicholson**: Spheroidal wave functions. The paper develops a new class of solutions of the equation of wave motion, in oblate spheroidal co-ordinates, satisfying boundary conditions which can be made identical with corresponding conditions in problems of solutions of Laplace's equation. The new solutions are not of the form of products of functions of single "normal" co-ordinates appropriate to the spheroid, but they nevertheless can be applied readily to the exact solution, without the use of harmonic series, of problems of diffraction of waves by circular discs.—J. V. **Howard** and S. L. **Smith**: Recent developments in tensile testing. When a steel test piece is pulled beyond a limiting stress, the removal and re-application of the load causes a loop to be traced in the load-extension diagram recorded by the Dalby autographic load-extension recorder. The extension which occurs when a loop is being traced is analysed into a proportionally elastic portion and a non-proportionally elastic portion (recoverable slip) which depends only on stress. Permanent set is the ultimate cause of rupture, and is caused by the act of looping. The stress required to produce a standard mean loop-width provides a means of comparing different steels as regards that property of the metal which is revealed by this method of testing. Under certain conditions of heat treatment and composition, no recovery takes place at ordinary temperatures; nor does steel recover if left in a state of stress.—F. C. **Harris**: The photo-elastic constants of glass as affected by high temperatures and by lapse of time. The stress-optical coefficients of several glasses, of known chemical composition, at different temperatures up to 400° C., with only one exception, show a general increase with rise of temperature. The exception was an extra dense flint, containing a high percentage of lead. The stress-optical coefficients increase comparatively rapidly during the first year or two after being cast, and finally settle down to a steady value.—A. L. **Narayan** and D. **Gunnaiya**: Absorption and dispersion of thallium vapour. The non-luminous vapour of thallium absorbs lines of sharp and diffuse series. At about 900° C. a number of bands of diffuse and complex structure, and some lines, made their appearance, probably due to Tl_2 molecules. The vapour does not exhibit any selective absorption in the region 0·9μ to 1·35μ, and that therefore $1,\pi_2 - 1,\pi$, is not the single-line spectrum of the metal. The work confirms the findings of H. Geisler and Prof. McLennan, that at λ5350·6 the vapour exhibits anomalous dispersion, though feebly. Further, the experiments indicate more prominently the existence of anomalous dispersion at λ3775·7.—R. d'E. **Atkinson**: Note on Vegard's theory of the aurora. The presence of solid nitrogen would not account for auroræ at great heights since (1) there probably cannot be a strong enough field to lift crystals; (2) the volume charge they would carry would be impossibly large if enough light were to be obtained; (3) the largest crystals that could be lifted would probably be completely vaporised by one electronic impact; (4) solid nitrogen probably cannot emit a narrow line. The possibility of low enough temperatures is disproved. The experimental evidence of Vegard is inconclusive. Two alternatives, in which the aurora is explained as a purely gaseous luminescence, are outlined, and the possibility that the gas might be oxygen instead of nitrogen (so far as 5578 is concerned) is discussed.—M. **Weinberg**: The spark spectra of indium and gallium in the extreme

ultra-violet region. The spark spectra were examined in both quartz and vacuum-grating regions. Since they oxidise very easily in air, their spectra in the quartz region were taken in hydrogen. There are altogether 107 indium lines in the quartz region, some of which are extremely faint. They extend over a range of 1855 to 2337 A.U. There are fewer gallium lines in this region. These range over 1855 to 2364 A.U. Both elements in the vacuum grating spectrograph show a great mass of lines in the extreme ultra-violet. On elimination of the impurities, however, it was found that there were 828 gallium lines ranging over region 157-2059 A.U., and 464 indium lines ranging over 161-2082. In gallium there were a few very faint lines extending so far down into ultra-violet as $\lambda = 126{\cdot}8$ A.U.—S. W. **Richardson**: The general law of electrical conduction in dielectrics.—T. **Lewis**: The interpretation of the results of Bucherer's experiments on e/m. The whole of the traces obtained by Bucherer in his e/m experiments may be used in order to verify the mass formula for the electron. The experimental traces confirm the validity of the Lorentz formula for high velocities provided electrons with these high velocities are emitted in sufficient number to produce the desired photographic effect. Electrons must be emitted with velocities up to at least 0·94 of the velocity of light. This is higher than the velocities recorded by Ellis up-to-date, but well within the range observed by Danysz.—A. M. **Mosharrafa**: On the quantum dynamics of degenerate systems. A set of quantum restrictions is suggested for degenerate conditionally periodic systems, in the form $Y_j = \tau_j h$, where Y_j is a specified "adiabatic invariant." The conditions are applied to the case of the hydrogen atom in the presence of an external electric field and lead to the adoption of "half-integral orbits" in the Stark effect. The origin of fractional quantum numbers is to be sought in the mechanism of degenerate systems.—E. G. **Dymond**: On the precise measurement of the critical potentials of gases. Automatic differentiation of the characteristic curves increases the sharpness of the bends in them. The reasons for the divergence of the value found for the first excitation potential of helium, 20·9 volts, from that calculated from the optical data, are discussed.—I. **Langmuir** and K. H. **Kingdon**: Thermionic effects caused by vapours of alkali metals. At high filament temperatures, positive ion emission becomes limited by the rate at which vapour comes into contact with the filament, all atoms striking the filament being converted into ions. This permits quantitative measurements of vapour pressure to be made. At lower filament temperature, electric image force causes a fraction θ of filament surface to be covered by a layer of adsorbed ions, which share electrons with the underlying metal. The resulting double layer causes increase in electron emission and corresponding decrease in positive ion emission. Electron emissions of more than 0·3 amp. per cm.^{2} at 1000° K. may be obtained in cæsium vapour 30° C. The theory of dilute adsorbed films ($\theta < 0{\cdot}2$) is developed. Equation of state for adsorbed film is found to correspond to ideal gas laws. For more concentrated films, attractive forces draw the ions together, and under certain conditions separate 2-dimensional phases appear. Heat of evaporation of adsorbed cæsium atoms on tungsten in the form of ions corresponds to 4·0 volts for dilute and 4·3 for concentrated films. From adsorbed oxygen on tungsten, heat of evaporation of cæsium ions is 5·1 volts.—C. Tate **Regan**: Dwarfed males parasitic on the females in oceanic angler-fishes (*Pediculati Ceratioidea*). Dwarfed males parasitic on the females are described in Ceratias (female, 1000 mm., male, 105 mm.) and Photocorynus (female, 65 mm., male, 10 mm.). Outgrowths from snout and chin of the male unite in front of the mouth and fuse with a papilla of the female. The skin of the two fishes is continuous, and beneath it the outgrowths of the male and the papilla of the female consist of highly vascular fibrous tissue: the blood systems of the two are continuous, a unique type of parasitism. In the male, teeth are absent and the gut is vestigial. Other ceratioids examined are all immature females: no free-swimming males are known in the group. The ceratioids are bathypelagic, piscivorous, solitary, and sluggish: they float about in the darkness of the middle depths of the ocean. It is suggested that the difficulty experienced by mature fish in finding a mate led the immature males to attach themselves to the females at the first opportunity, with the result that in the end the males became dwarfed and parasitic.

Royal Microscopical Society (Industrial Applications Section), October 22.—R. H. **Greaves**: Supersaturated solid solutions. In many alloy systems, the limit of saturation of the α solution decreases with fall of temperature. This is so with a group of ternary alloys of copper and aluminium with nickel, also with manganese and with other elements. These α solid solutions can be obtained in the supersaturated condition at atmospheric temperature by quenching. Subsequent heat treatment hardens the alloy by precipitating the excess of the dissolved constituent. To obtain maximum hardness, the whole of the excess must be precipitated in extremely fine particles (critical dispersion). These are far below the limit of visibility under the microscope ($0{\cdot}25\mu$ or 1000 atoms diameter). This does not seem possible with the alloys mentioned, since a treatment which ensures complete precipitation at the same time induces coalescence. It is possible, however, in aluminium alloys and is illustrated by the ageing of duralumin, and some other alloys containing magnesium, at atmospheric temperature. Increased resolving power would enable the study of the precipitated particles into the region of the critical dispersion, but it has been possible to interpret the structure by inference from other tests, and the practical problem of correct heat treatment has therefore not been delayed.

Faraday Society, November 17.—A. P. **Laurie**: Note on the expansion of water while freezing. Assuming that the atomic diameters based on Bragg's crystal model for ice are true for liquid water, and that liquid water at 0° is a trihydrol, it follows as a geometrical necessity that there will be an expansion from 1 to 1·088 when ice melts. This gives a sp. gr. for ice of 0·918; and the experimental value is 0·917, thus confirming the original assumptions.—R. W. E. B. **Harman** and F. P. **Worley**: The hydrolysis of alkali cyanides in aqueous solution. The vapour pressure of hydrogen cyanide over solutions of potassium cyanide was compared with that over solutions of hydrocyanic acid, and it is shown that the degree of hydrolysis of sodium cyanide at 25° at all concentrations is the same as that of potassium cyanide. The effect of temperature was also studied. The constancy of the hydrolytic constants at different concentrations at each temperature, the agreement of the values at different temperatures with the Van 't Hoff isochore, and the agreement between the calculated heat of hydrolysis and the measured heat of neutralisation appear to confirm the accuracy of the values arrived at for degree of hydrolysis at the various concentrations and temperatures employed.—S. S. **Joshi**: Viscosity of reversible emulsions.

Viscosities of water-in-oil emulsions prepared from castor oil, olive oil, and paraffin oil by means of four monovalent soaps are determined. Viscosity increases with increase of the dispersed phase and is a maximum at the reversal point, which is followed by a sudden drop in viscosity upon inversion. The concentration and the specific chemical nature of the emulsifying agent have no effect on the viscosity of the emulsion. Hatschek's equation for the viscosity of the emulsoids is not followed; observed viscosities are in approximate agreement with those estimated by Einstein's equation for suspensoids; Arrhenius' equation applies better still. The size of the grains of the water-in-oil emulsions may increase with increase in the proportion of the aqueous phase.—D. B. **Macleod**: On the viscosities of liquids at their boiling-points. Boiling-points are unsatisfactory temperatures at which to compare the viscosities of liquids. By correcting the boiling-points to a condition of equal free space, the viscosities of liquids become proportional to their molecular weights in the liquid state. Such a condition of equal free space corresponds very closely to a reduced temperature on the basis of Van der Waal's equation of state.—D. B. **Macleod**: The kinetic theory of evaporation. It is assumed that the ratio of the density of the vapour above a liquid to the density of the liquid is really the ratio of the number of molecules with sufficient speed to escape from the liquid to the number with insufficient speed. Thus if D_v and D_e are the densities of the vapour and liquid respectively, then

$$\frac{D_v}{D_e}=\frac{N_s}{N_i},$$

where N_s is the number of molecules with sufficient speed to escape and N_i the number with insufficient speed. It is shown that the results which follow from this assumption are so simple and satisfactory as to make the truth of the assumption extremely probable. The experimental data used are those given by Ramsey and Shields.—J. T. **Howarth** and F. P. **Burt**: New design for apparatus to measure the coefficient of deviation from Boyle's law and the determination of this coefficient for acetylene. A modified apparatus for measuring the compressibility of gases has been designed in which the whole volume of the gas and also the mercury column which registers the pressure are kept at the temperature of melting ice. The coefficient of deviation from Boyle's law at 0° C. for acetylene between 0 and 1 atmosphere is −0·00884.

MANCHESTER.

Literary and Philosophical Society, December 2.—T. A. **Coward**: Migration may be visible or invisible. The passage of large bodies of waders, and of swallows, martins, and swifts during daylight, are examples of visible migration; but the majority of species pass unseen in favourable circumstances, probably because they travel at night or at too great an elevation for human vision. When these species are seen in any numbers, as during unfavourable weather at the coastwise lights, migration is abnormal. The fact that birds frequently travel against the wind or with the wind on a flank does not prove that they prefer this method; nor does the fact that airmen but seldom meet with birds at high altitude annul the possibility of high flight; the birds may have wandered into unfavourable currents. Coasts and river valleys are followed, but there are also cross-country migrations. Wind driftage and contrary currents explain many of the occurrences of migrants in unexpected places.

SYDNEY.

Royal Society of New South Wales, September 3.—Dr. C. Anderson, president, in the chair.—E. **Cheel**: Notes on Boronia in the Pinnate Section, with a description of a new species. The plants, which are from the Richmond River district, have a superficial resemblance to the "Pink Boronia" (*B. floribunda*) of the Sydney district, but the leaves are smaller and the whole plant is more or less hairy and not glabrous, as is the case with "Pink Boronia." The oil contained in the leaves has a fragrant odour, somewhat resembling safrol, and it is therefore proposed to call the new plant *Boronia safrolifera*.—T. **Hodge Smith** and Tom **Iredale**: Evidence of a negative movement of the strand line of 400 feet in New South Wales. A series of sandstone blocks has been trawled along the 70 fathom line from Long Reef, north of Sydney, to south of Montague Island, a distance of about 200 miles. The soundings along this line show coarse sand and rocks, and the boulders are composed of very coarse sand grains similar to that of a beach, and not like the fine soft sand normally found at such depths. One of these blocks was a mass of scallop and other shells cemented together with this coarse sand. The shells belong to littoral species at present living on the coast of Tasmania, while the existing molluscan fauna at the place differs notably in detail from the association of molluscs in this block. These blocks seem to represent an ancient coastline which has been drowned in recent times, probably simultaneously with the movement that broke through Bass Strait.—S. L. **Martin**: The change of resistance of molybdenite due to light. If the contacts are shielded, a strip of molybdenite 0·001 cm. in thickness suffers a decrease in electrical resistance, when light is incident on it, the red end of the spectrum producing the greatest change. This change is constant, providing the current density is less than about 0·1 amp. per sq. cm. and is proportional to the intensity for small intensities. For white light, the source being a hundred candle power pointolite lamp at a distance of 75 cm., the change was of the order of 1 ohm in 500.

Adrian: The Chronaxie of Ventricular Muscle.

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch, Junior Section (at Municipal College of Technology, Manchester), at 7.—F. W. Rowe: The Value of Technical Information in Foundry Work.

HULL ASSOCIATION OF ENGINEERS (at Hull Municipal Technical College), at 7.15.—J. Key, Jr.: Autogenous Welding (Lecture).

MONDAY, DECEMBER 15.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—F. C. Raphael and others: Discussion on The New Wiring Regulations of the Institution.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.—G. Rogers: Automatic and Semi-automatic Mercury-vapour Rectifier Substations.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates Section), at 7.—E. G. Davies: Some Aspects of Works Management, with a View to Cutting Costs of Production.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—A. J. Davis: Shop Fronts and their Treatment.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Prof. L. J. Russell: Science and Philosophy.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Major R. E. Cheesman: The Deserts of Jafura and Jabrin.

INSTITUTION OF AUTOMOBILE ENGINEERS (Scotland Section) (at Royal Technical College, Glasgow).

CHEMICAL INDUSTRY CLUB (at 2 Whitehall Court).

TUESDAY, DECEMBER 16.

ROYAL DUBLIN SOCIETY, at 4.15.

ROYAL STATISTICAL SOCIETY, at 5.15.

INSTITUTION OF CIVIL ENGINEERS, at 6.—Dr. T. E. Stanton: Report on the Measurement of the Pressure of the Wind on Structures.

INSTITUTE OF MARINE ENGINEERS, at 6.30.—E. G. Warne: Development of Steam and of Oil Engine Machinery for Propulsion.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at 17 Albert Square, Manchester), at 7.

ILLUMINATING ENGINEERING SOCIETY (at the Lighting Service Bureau, 15 Savoy Street, W.C.), at 7.—Further Particulars and Demonstrations of Recent Advances in Electric Lamps and Lighting Appliances, based on the Report presented at the Opening Meeting on November 18 (with special reference to Shop-window Lighting).

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. D. Johnston: A Winter Holiday.

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7.30.—J. Dunlop: The Internal Combustion Locomotive.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Rev. H. W. Williams: Some Customs, Beliefs, and Traits of the Maori.

WEDNESDAY, DECEMBER 17.

SOCIETY OF GLASS TECHNOLOGY (London Meeting), at 2.30.

ROYAL METEOROLOGICAL SOCIETY, at 5.—C. E. P. Brooks: The Problem of Warm Polar Climates.—Sir Napier Shaw: Winds and Temperature in a Dry Atmosphere.

LONDON AND PROVINCIAL ANTI-VIVISECTION SOCIETY (at Victory House, Leicester Square, W.C.), at 5.30.—Dr. H. F. Woods: Cancer Research and Why it Fails.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. J. D. Falconer: The Geology of Nigeria (Lecture).

NEWCOMEN SOCIETY (at 17 Fleet Street, E.C.), at 5.30.—E. A. Forward: The Development of the Cylinder Boring Machine.

INSTITUTION OF CIVIL ENGINEERS (Students' Meeting), at 6.—H. C. Reeves: Mangahao Hydro-electric Power-station.

BRITISH SOCIETY OF MASTER GLASS-PAINTERS (at Art Workers' Guild, 6 Queen Square, W.C.), at 6.—B. Rackham: The Stained Glass at the Victoria and Albert Museum.

RADIO SOCIETY OF GREAT BRITAIN (Annual General Meeting) (at Institution of Electrical Engineers), at 6.—C. F. Elwell: Photo-electrics (Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Centre) (at Armstrong College, Newcastle-on-Tyne), at 7.15.—Prof. G. W. O. Howe: World-wide Radio Telegraphy (Faraday Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.

ROYAL MICROSCOPICAL SOCIETY, at 7.45.—Dr. F. W. R. Brambell: The Part played by the Golgi Apparatus in Secretion and its Subsequent Re-formation in the Cells of the Oviducal Glands of the Fowl.—Prof. Ekendranath Ghosh: A New General Classification of Protozoa.—Dr. R. J. Ludford: Further Notes on the Demonstration of the Golgi Apparatus by Osmium Impregnation Methods.

INSTITUTE OF CHEMISTRY (London Section), at 8.

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (Annual Meeting) (at Royal Society of Medicine), at 8.30.—Dr. J. Rickman: The Development of the Psycho-Analytical Theory of the Psychoses.

INSTITUTION OF AUTOMOBILE ENGINEERS (Birmingham Section) (at Chamber of Commerce, Birmingham).

INSTITUTION OF AUTOMOBILE ENGINEERS (Wolverhampton Section).

THURSDAY, DECEMBER 18.

LINNEAN SOCIETY OF LONDON, at 5.—Major T. F. Chipp: The Fruiting of the Groundnut, shown in lantern slides.—E. J. Collins: The Physiological Aspect of Blight Infection (*Phytophthora infestans*) of Potatoes.—W. P. Westell: Remarkable Form of *Pastinaca sativa*, new to Britain.—Major R. B. S. Sewell: A Study of the Andaman Sea Basin.

ROYAL AERONAUTICAL SOCIETY, at 5.30.—A. R. Watson Watt: Recent Studies on Radiotelegraphic Atmospherics.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—D. Murray: Speeding up the Telegraphs: A Forecast of the New Telegraphy.

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates Meeting) (at Watergate House, Adelphi), at 7.30.

INSTITUTE OF CHEMISTRY (Belfast and District Section) (at Queen's University, Belfast), at 7.30.—Dr. R. C. Johnson: The Rutherford-Bohr Atom from a Chemical and Physical Standpoint.

CHEMICAL SOCIETY, at 8.—W. H. Patterson and J. Duckett: A Method of Determining the Presence or Absence of Complex Salts or Ions in Dilute Aqueous Solutions. Dr. C. K. Ingold: The Nature of the Alternating Effect in Carbon Chains. Part I. The Directing Influence of the Nitroso-group in Aromatic-substitution.—Dr. C. K. Ingold and S. D. Weaver: The Additive Formation of Four-membered Rings. Part VI. The Addition of Azo-compounds to Ethylenes and some Transformations of the Dimethylene-1:2-di-immine Ring.—F. R. Goss, Dr. C. K. Ingold, and Prof. J. F. Thorpe: The Chemistry of the Glutaconic Acids. Part XVII. Three-carbon Tautomerism in the Cyclopropane Series. Part 4.—Dr. C. K. Ingold: The Condition Underlying the Formation of Unsaturated and Cyclic Compounds from Halogenated Open-chain Derivatives. Part IV. Products derived from Halogenated α-methyl Glutaric Acids.

SOCIETY OF DYERS AND COLOURISTS (West Riding Section).—J. W. Radcliffe: The Blending of Materials in the Woollen Trade with relation to Dyeing.

INSTITUTION OF MECHANICAL ENGINEERS (Manchester Section).—Prof. F. C. Lea: The Effect of Low and High Temperatures on Materials.—J. M. Lessells: The Elastic Limit in Tension and its Influence on the Breakdown by Fatigue.

FRIDAY, DECEMBER 19.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Report of the Wire Ropes Research Committee.

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section, jointly with Institute of Chemistry) (at Chamber of Commerce, Swansea), at 6.30.—Prof. R. V. Wheeler: Fire Damp Explosions (Lecture).

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section) at 7.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) at 7.—R. H. Lawton: Specialisation *v.* Versatility.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle-on-Tyne), at 7.—Discussion: Steam *v.* Electric Auxiliaries.

INSTITUTION OF AUTOMOBILE ENGINEERS (London Graduates Meeting) (at Watergate House, Adelphi), at 7.30.—H. E. Merritt: Tooth Gearing.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Newcastle-upon-Tyne), at 7.30.—J. L. Taylor: Theory of Longitudinal Bending of Ships.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Graduate Section) (at Cleveland Institution, Middlesbrough), at 7.30.—Dr. E. V. Telfer: Technique and its Acquisition in Shipbuilding.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—Col. the Master of Sempill: Aircraft in Japan.

SOCIETY OF DYERS AND COLOURISTS (Midlands Section) (at Municipal Technical School, Leicester).—S. R. Trotman and R. W. Sutton: The Destruction of Wool by the Action of the Atmosphere.

SOCIETY OF DYERS AND COLOURISTS (Scottish Section).—J. W. Wilson: Celatine Colours and their Application.

PUBLIC LECTURES.

SATURDAY, DECEMBER 13.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: The Glory that was Thebes.

TUESDAY, DECEMBER 16.

ROYAL BOTANIC SOCIETY OF LONDON, at 3.—Prof. Bickerton: The Correlation of Science (3). Waves and Vibrations.

KING'S COLLEGE, at 5.30.—M. Kaye: F. H. Bradley—The Absolute and Human Personality.

River Pollution.

ONE does not need to have read the "Compleat Angler" to know that fishing is among the most humanising of crafts. Up and down the country in all possible — and in some impossible — places, gentle patient citizens will be found practising the art. If they catch fish, so much the better: if not, they have been in pleasant places and communed with peace; like the small girl whose pet pigeon had flown away, fishermen "adore hope," and no one can doubt that they are the better for it. With them we have to think of the other gentle men, the field naturalists, who, whether their particular pursuit be rotifers, or snails, or plants, or what not, have one of their happiest hunting grounds in and by our rivers and streams, and steadily go on adding up our sum of natural knowledge.

Besides these craftsmen there are the people who find in the activity of running water the rest and comfort that their souls need and walk by the river just because it is beautiful, and they find that it does them good. They may all well wonder why fish and animalcules and peace should be allowed to disappear together in the filthy sewers which stand for the Wear in the gorge at Durham, or for the Mersey in the lovely Marple valley. Incidentally too, as we learn from the "Report of the Proceedings under the Salmon and Freshwater Fisheries Acts for the years 1922 and 1923,"[1] the salmon caught in the Herefordshire Wye in 1923 had a selling price of 15,000*l.*, those from the Tees of 28,000*l.* It is not suggested that all the rivers in Great Britain are potential salmon fisheries, but there are evidently commercial considerations in favour of biologically clean streams.

The problem of river pollution is one of the problems of industrialisation. Pollution comes mainly from two sources—domestic sewage and industrial wastes. The former is seldom now discharged into rivers in a crude state except from quite small communities: modern methods of sewage purification are efficient and quickly increasing in efficiency as the principles of biological defæcation become better known, and if domestic sewage were all there was to deal with, clean rivers would appear to be well within reach. But a town's sewage often contains, in addition, trade wastes and effluents which hamper and retard the purification of the domestic excreta by poisoning the live things on which that depends, and they act equally harmfully on the flora and fauna of the rivers into which they find their way. Often, too, large works of one kind or another will pour their undiluted wastes into a stream and kill everything that is alive in it. In milder cases these

[1] Ministry of Agriculture and Fisheries (H.M. Stationery Office, 1924). 3s. The Ministry has also published a useful booklet, "River Pollution and Fisheries," price 3*d.*

effluents may produce surprisingly large effects by their action on some specially sensitive member of the fauna or flora: in this way the self-regulation of the aquatic communities is upset and deterioration spreads all through the ecological complex.

Among the more sensitive of the large and familiar animals are salmon and trout, which demand a very high degree of purity and oxygenation in their water: in the hotter months, indeed, it seems that trout must often be living near the margin of the oxygen supply that they will tolerate, and under these conditions a slight degree of extra pollution may turn the scale against them. There is, however, too great a tendency to think of the question in terms of these "sporting fishes": they are the pastime and refreshment of the few, and in reality coarse fish are a good deal more important, if only because there are many more of them and many more people anxious to take their chance of catching them.

What is being done to purify the foul rivers and prevent further contamination? The old pollution Acts have evidently failed even to stop matters getting rapidly worse in recent years. In 1921 a Standing Committee on Rivers Pollution, composed mostly of persons directly interested in fisheries, was set up, and in 1922 it commenced, under the energetic superintendence of Dr. E. C. Jee, of the Ministry of Agriculture and Fisheries, a survey of selected rivers in Great Britain.

A good deal of progress has already been made with this survey, and valuable information has been obtained as to the actual degree of pollution, its sources and effects. Specific tests of the poisonous action of effluents on fish are also carried out at the Ministry's little station at Alresford, where the problem of tarring roads with safety to the neighbouring watercourses was so successfully solved. More immediately useful still, committees have been got together in the different fishery districts where the local interests and knowledge of anglers and manufacturers are combined to deal directly with local problems. To aid the Standing Committee in the more technical chemical and biological questions which arose, a Scientific Advisory Committee was added in 1924.

Through this organisation the most essential step towards reform has been taken and much has been done to rouse general interest in the subject. In 1923 a new pollution Act, after many vicissitudes and delays, received the Royal assent. Under this, it is an offence to cause pollution of any waters containing fish of any kind so as to render such waters poisonous or injurious to fish or to their spawning grounds, spawn or food. It is an obvious defect that the Act permits the unrestrained pollution of waters which do not contain fish, and it also allows as a defence of existing pollution the plea that "the best practicable means within a reasonable cost" have been employed to prevent it.

Legislation, in short, follows the lines to which we are accustomed in Great Britain. We do not say, as does New York, "smoke is forbidden" and make that the beginning and end of it: we prefer to dally with discussions of "brown" smoke and "black" smoke and put up with dirty towns. In the end, perhaps, we get the right result on a permanent basis backed up by a convinced public opinion, but this takes a long time. More drastic powers might well have been obtained to deal with difficult manufacturers who naturally affirm, to begin with, that any steps towards purification would ruin them, though they may end up by finding that cleansing their effluents may yield saleable products more immediately remunerative than the blessings of the community.

In these several ways, then, the *ad hoc* problems are beginning to be dealt with. But we feel that progress will soon get slow unless steps are taken to promote our knowledge of the fundamentals of river life. It needs no scientific training to be sure that the Tyne in its lower parts is not what it should be, and no more than a sanitary inspector's acumen to trace the trouble to its sources. But all experience tells us that empiricism of this sort will take us only a certain way. Even now it can make no serious attempt to explain why in the smaller Hertfordshire rivers, for example, fish of all kinds have almost disappeared in the last ten years, leaving the streams to casual inspection reasonably clean, bright and weedy.

Fresh water ecology has scarcely been thought of in Great Britain, and it offers an open field to workers of many kinds to help to work out how the complex communities of plants and animals live and move and have their being, and what are the conditions which determine their stabilisation at different levels. To take the crudest example, the foods of fishes and the foods of this fish food are simply not known any more than, until recently, were the foods of our birds known. There is also great ignorance as to what exactly various degrees of pollution of different kinds do, what chemical changes are produced in the water, and which components of the fauna and flora are affected and how.

Beginnings in a small way are being made in various places, but what is most deeply needed is an institution round which this work could centre. There are a few marine biological stations, but there is no corresponding focus for fresh-water work. No one interested in fishing or in the amenities of the countryside could do better than to provide such a station for investigating the conditions of life in the rivers and streams of Great Britain.

Physiological Optics.

Helmholtz's Treatise on Physiological Optics. Translated from the third German edition. Edited by Prof. James P. C. Southall. Vol. 1. Pp. xxii+482. (Published by the Optical Society of America, 1924. To be obtained from Prof. F. K. Richtmyer, Cornell University, Ithaca, New York.) 7 dollars.

Let us now praise famous men.
The Lord manifested in them great glory,
Even His mighty power from the beginning.
Such as did bear rule in their kingdoms:
And were men renowned for their power,
Giving council by their understanding:
Such as have brought tidings in prophecies;
Leaders of the people by their councils,
And by their understanding men of learning for the people.
Wise were their words in their instructions.

Ecclesiasticus, 44, 1-6.

THREE years ago the Optical Society of America celebrated the centenary of the birth of Helmholtz and decided that a lasting commemoration should be established by the publication of an English translation of his great book on physiological optics. So at last a deep reproach has been lifted from the record of English scientific literature. "The very existence of this book in English," says the editor of the translation, "should lead to new treatises and new text-books, which are sorely needed at present." The third German edition, containing the text of the first edition with supplements added later by Helmholtz himself, by the late Prof. Nagel, and by Profs. Gullstrand and v. Kries, was chosen for translation. The present volume is enriched by six of Helmholtz's supplements, three of Gullstrand's notes, and six appendices by Gullstrand. Special interest is given by the inclusion, as the sixth appendix, of a chapter on ophthalmoscopy taken from Prof. Gullstrand's work on dioptrics. This is one of the features which gives distinctiveness to the English edition, for it did not appear in the third German edition.

The name of Helmholtz is outstanding in science as that of an original investigator and breaker-out of new paths in several directions, and as that of a man of rare genius whose work was of epoch-making quality. In this respect his "Physiological Optics" stands amongst such works of the last century as the magnificent fragment known as Thomson and Tait's "Treatise," or Maxwell's "Electricity and Magnetism." It is well that it should be placed alongside them in its English garb. The stamp of endurance marks it out as the work of one who, to use his own words regarding Young, was "leaping before his time." The present volume teems with examples of the permanence of its value and the manner in which modern work forms its fitting development.

No new treatise, say the German editors, has superseded Helmholtz's work—it

"bears the stamp of a genuinely classical treatise which will always retain its value, even if new investigations lead to some modifications here and there of the points of view which Helmholtz himself entertained." "In the theoretical and for the most part solid territory belonging to the physiology of both the sensations and the perceptions of vision, the editors considered . . . that even where it was necessary to record a notable advance of scientific investigation since the date of the appearance of the first edition of the Physiological Optics, a natural outcome of this kind should not involve at all an adverse attitude towards the theories of Helmholtz."

The foremost reason given for the decision to republish the text of the first edition

"was the consideration that the whole imperishable significance of Helmholtz's achievements in the domain of the physiology of vision, the elegant physical methods which he adopted and improved, his painstaking observations of the sensations themselves and the allied psychical phenomena, the mathematical analysis and philosophical and critical discussion, all these characteristic features are essentially interwoven with the first edition of the Physiological Optics. It is the classical work which marked the dawn of a new era in the science of the physiology of the senses."

Another reason which is also given does not apply to the subject matter of the first volume. Whatever exception may be taken to the view involved in it, there will probably be no difference of opinion regarding the wisdom of the conclusion. The great extent and invaluable nature of the supplementary work included in the third German edition left to the translators no other choice than that of its adoption by them. The bulk of the new matter published in the first volume almost equals that of the original matter, and it deals with every division of the subject.

The aim and the hope of Helmholtz in undertaking his work was clearly stated by him in his first preface. "An effort had to be made to introduce law and order in this region and to rid it of the curious contradictions which have heretofore impeded progress. I have proceeded on the conviction that law and order, even if they are not fundamentally sound, are better than contradictions and lawlessness." "I trust that competent judges will bear in mind the difficulty and intricacy of the problem to be solved when they are disposed to find fault." These defects were the rank growths against which he raised his axe: and in pioneer work "a man was famous according as he had lifted up axes against the thick trees." The true pioneer possesses the sense of direction; he rarely misses his aim or even takes a wrong detour. The

extent to which this was true of Helmholtz is apparent throughout this volume.

Helmholtz treated the whole subject under three headings: (1) the theory of the path of the light in the eye, (2) the theory of the sensations of the nervous mechanism of vision, (3) the theory of the interpretation of the visual sensations. It is with the first of these that this volume deals. The magnitude of the new work in dioptrics is so great that its limitation to nearly the same bulk as that of the original treatment has only been attained by the omission of the mathematical proofs. For these the reader has to refer to Prof. Gullstrand's original papers. Yet that will perhaps be found by the majority of readers to be no disadvantage. In this way the line of argument is more lucid and the presentation more concise. It suits the requirements of most ophthalmologists and is not without advantage to the student of physics. The editor of that subject

"has endeavoured to limit himself mainly to the essential facts in the region where notable advances have taken place, and to present these modern ideas in as simple a form as possible for a reader who is not versed in higher mathematical analysis. An outline of the new theory is given here for the first time, including the previously unknown laws of optical imagery in media of variable index of refraction which could not be omitted because, first of all, they are essential for finding the data of a schematic eye that will agree with the facts as they are now known, and also because these considerations are of importance in connection with the effort to substitute a new theory of accommodation in place of Helmholtz's theory, whereas undoubtedly this attack as well as others of a similar kind are to be regarded as affording new supports to the author's views on this subject."

In practical ophthalmology, Helmholtz's instrument, improved no doubt, is still the one in use. "The ophthalmologist who uses the ophthalmoscope every day . . . knows best how to estimate Helmholtz's immortal service to mankind." Its use in various forms and for various purposes is treated fully by Gullstrand. One of his notes refers to the solution of a problem, "which could not even have been proposed at the time when the ophthalmoscope was invented." The advantages and disadvantages of the several modifications are discussed.

The value of Gullstrand's contributions may be judged from the fact that, previous to his work, the optical laws of the formation of images were only worked out under highly limiting conditions which prevented the results from having application to the problems of imagery in the eye. Very high approximation to correct results could be got by laborious calculations, so that the construction of optical instruments possessing axial symmetry was highly developed. But physiological optics requires, for the sufficiently accurate solutions of its problems, that the conditions shall be much wider than those imposed in normal optical construction. Therefore Gullstrand determined the general laws of optical imagery, and then, applying them to the practical problems of vision, gave a fresh illustration of the further development of one science in consequence of the expansion of another. The beautiful tale is told in his appendices. His work is worthy of a position beside that of the master.

All through this volume may be found references to the value of the master's work.

"If the form of the cornea is to be calculated by means of relations that are true for an ellipsoid, undoubtedly the best way is to go about it regularly and to calculate the constants of the ellipsoid by the method given by Helmholtz."

"Although more recent investigations tend to give rather lower values, there hardly appears to be any sufficient reason as yet for modifying Helmholtz's schematic value beyond merely discarding the figure in the fourth decimal place as not being at all certain."

"Unless a Blix ophthalmometer is available, Helmholtz's method of ascertaining the positions of the surfaces of the crystalline lens is still to-day the best method."

"If the sources of error are taken into account, depending on the asymmetrical flattening of the cornea, on the unknown form of the anterior surface of the lens, and on using a total index for the index of refraction of the lens, there can be no doubt that Helmholtz's number is within the possible limits of error." "The same conclusion has been reached also concerning the radii of curvature of the two surfaces of the lens."

"Modern investigations have established that the theory of the mechanism of accommodation remains unchanged, in all essential features, just as Helmholtz, by a real inspiration of genius, considering the state of knowledge of that time, conceived it."

An example of misconception of Helmholtz's view is discussed in the fourth appendix.

"Helmholtz's own words are: 'Stretched elastic membranes which contain an invariable volume of an incompressible fluid, and which are attached by a circular margin, as the zonule is to the choroid, tend to approach the form of a segment of a sphere in proportion as its tension increases. . . .' To infer from this that the anterior surface of the lens, as it bulges forward with a decrease of tension in accommodation, is obliged to approach the form of a sphere, so that an increase of curvature can be produced by the increase of tension, involves conceptions that are incompatible with the mathematical knowledge of a Helmholtz."

A second misconception is considered.

"Helmholtz's famous dictum, that the monochromatic aberrations of the eye are such as would not be tolerated in any good optical instrument, is sometimes construed to mean that the eye is a very badly constructed optical affair—which Helmholtz never said

and certainly did not mean. But another question that this statement raises is whether these aberrations are not serviceable and what is their purpose. . . . The monochromatic aberrations are a witness for the perfection of the eye, if what is meant by the perfection of an optical instrument is good convergence of the rays to the degree that is needed to obtain the greatest useful sharpness of image, anything in excess of this being sacrificed in order to gain some other end."

Unfortunately, these two misconceptions regarding Helmholtz's views do not stand alone.

The American Optical Society, the editor with his collaborators, and the printers are alike to be congratulated on this issue of an epoch-making book, worthily worked up to the level of modern knowledge. It is the most suitable memorial which could have been raised to the memory of Herman v. Helmholtz, physicist, physiologist, and mathematician. The reward of the contributors to the German and the American issues will be forthcoming if the response for which the editor hopes comes in the way of new advances. This volume should be at the disposal of every worker who is specially interested in optics in its purely physical, its physiological, or its ophthalmological bearings.

W. PEDDIE.

Phylogeny as an Independent Science.

Geschichte der Organismen. Von Prof. Victor Franz. Pp. xiii+948. (Jena: Gustav Fischer, 1924.) 36 marks.

THE author of this ponderous work is the occupant of a chair of "phylogeny" in the University of Jena, and in this volume he has apparently attempted to justify his position, for he treats of the evolutionary history of every phylum both in the animal and in the vegetable kingdom! Both the title of the chair and of the book must awaken amazement in simple British minds. What is phylogeny apart from zoology and botany? Is not the specialist in botany or in zoology the only person competent to construct even a plausible phylogeny in either science? But perhaps we might expect in a volume like this to find the foundations for phylogenetic hypotheses critically examined: we might hope to have the value and the limitations of the evidence from fossils discussed; the theory of recapitulation explained and its validity determined. Such questions seem suitable for a book by a professor of phylogeny in general. If such were our expectations we should be bitterly disappointed. The book opens with a chapter devoted to a sketch of the physical geology of the globe and the changes which sea and water have undergone since the Cambrian. Then follows an account of the Darwinian theory of evolution with references to De Vries's mutations, Mendelism, and to direct adaptation and Lamarckism. The discussion on evolution is succeeded by a section on "Body and Soul" (Körper und Geist) in which we are informed by Prof. Franz that when the body dies, the "ego" is dissolved (how does Prof. Franz know this?), but that the "psychical" (whatever this may mean) persists. After this we reach a section dealing with the supposed characters of the first living beings and the manner in which they were derived from inorganic matter. Then we plunge into the detailed phylogenies of the various classes, first of plants and then of animals.

Now, no reviewer—least of all the present one—could possibly claim to be a competent judge of the plausibility of all these hypothetical phylogenies, and so we have tested their general value by looking critically at those in which we were most familiar with the evidence, namely, those contained in the invertebrate section of the animal kingdom. We may, however, remark in passing that some of the botanical theories seem to us extraordinary. Because its sexual germ-cells (oospores and antherozooids) resemble the ova and sperm of animals, the brown alga Fucus is regarded as closely resembling the original primitive organism from which all the rest, both animals and plants, have sprung. Consequently the unicellular protozoa are regarded as secondary degenerations of multicellular ancestors, and isogamy or the union of similar gametes is derived from the fertilisation of an egg by a spermatozoon. Verily all things are possible to him that believeth! We can only say that Prof. Franz's taste in these matters is widely different from our own. We might remind Prof. Franz that amongst the most primitive type of animal, namely, Amœba and its allies—the Foraminifera—isogamy is the rule, and that typical ova and spermatozoa are not encountered until we reach the sponges. But perhaps the most relevant criticism of theories such as these is that until the postulates underlying the construction of phylogenies are discussed and explained, one theory is really as good as another.

Turning now to the account given of the phylogeny of the principal invertebrate stocks, we can only characterise most of them as most unsatisfactory and based largely on lack of knowledge of the most recent researches. Thus the Turbellarian worms are termed "cœlomate" because they possess distinct genital organs and a cellular mass termed "mesoderm" between skin and gut lining, though no vestige of a true cœlom can be detected at any stage in their life-history. Not a word is mentioned of Lang's brilliant theory of their derivation from Ctenophora, though this theory has acquired strong support from

the discovery of creeping Ctenophora like Ctenoplana, and of a true ctenophore larva in the life-history of Coeloplana which in its adult condition closely resembles a turbellarian worm. When we turn to the chapter dealing with the phylogeny of the Crustacea, we find the Nauplius larva, which appears in the life-history of so many Crustacean stocks, and evidently represents in some disguise or other a common ancestor, regarded as representing a "metatrochophore" stage of the annelidan ancestor. But Walcott in his account of the mid-Cambrian fauna of British Columbia has described primitive arthropods which may well have been the actual "Nauplius" ancestor in the flesh. Such is "Marella," which in general structure is a shortened trilobite carrying attached to the hinder part of its body the foliaceous appendages characteristic of Trilobita; but the first three segments carry elongated limbs corresponding to the Nauplius appendages. Prof. Franz, in seeking for light on the ancestry of a group in the structure of a larva, neglects altogether to discuss the *simplification* of ancestral structures in the larva and its meaning and significance, so that in regarding one structure as primitive and another as secondary, he seems to proceed in an altogether arbitrary manner.

As another good example of superficial and crude reasoning based on lack of knowledge of recent work, we may refer to Franz's account of the phylogeny of the Echinodermata. The cystids are regarded as the ancestors of the whole group. It is admitted by all that the cystids developed into the crinoids, which they resemble in possessing a dorsal stalk and a lateral anus. But Franz derives from them also the whole of the Eleutherozoa (starfish, sea-urchins, and sea-cucumbers) in which the place of the aboral stalk is occupied by the anus. Of these the sea-cucumbers, supposed to be the most primitive, are stated to have branched off earliest from the cystidean ancestor, then the sea-urchins, and lastly the starfish. But if a cystid (of the internal anatomy of which we of course know nothing) really was like a crinoid in its soft structures, then it must have been widely different from the common ancestor of the Eleutherozoa. For in all three divisions of these, the central axis of the genital system, the so-called "genital stolon," is closely associated with the primitive stone-canal, whereas in crinoids these two structures are entirely separated and have no relation to each other whatever. The anus in primitive Eleutherozoa is always close to the aboral pole, and the course of the alimentary canal shows no resemblance to the spiral gut of crinoids.

Prof. Franz refuses to accept the identification of the "sucker" of attachment of many of asterid larvæ with the attachment of the stalk of the crinoid. Here again is evidence of unawareness of modern work, for, as Bury first showed, the Crinoid larva exhibits a rough correspondence in its organs with the Bipinnaria larva of the Asteroidea. Now in both larvæ the "sucker" of fixation is of exactly the same form and is developed at the same place. It comes to occupy totally different positions in the adult bodies of the two groups on account of the different character of the metamorphosis in each case. These different metamorphoses point strongly to a primitive divergence in habits between the ancestors of the two groups which led to their separation long before even the simplest cystoid form had been attained. If we now turn to the development of the sea-urchins, we find that the young sea-urchin begins its post-larval life in a form which is to all intents and purposes that of a starfish, and that the globular form is only gradually attained as growth proceeds. Thus we see how ill-founded is Franz's comparison of the cystid and the echinoid because both have a spherical shape.

When we reach the part of the book dealing with vertebrata, there is of course less opportunity for the presentation of crude ideas since the palæontological history of the vertebrate is relatively so well known. Yet even here the author seems totally unacquainted with recent embryological work which tends to establish the lateral fold theory of the paired limbs beyond all reasonable question; and commits himself, though with some hesitation, to the exploded theory of Gegenbaur that the limbs arose from displaced gill-arches.

Whilst, however, we regard Prof. Franz's methods of dealing with phylogeny as mistaken, and lament the absence of any attempt to set forth and defend the principles on which phylogenetical reasoning must be founded, yet the reader will find—especially in the part devoted to vertebrata—a large collection of useful facts amongst which the data which have been brought together throwing light on the origin of our domestic animals are particularly valuable. E. W. M.

The Electricity of Thunderstorms.

Die Elektrizität der Gewitter. Von Dr. K. Kähler. (Sammlung Borntraeger, Band 3.) Pp. 148. (Berlin: Gebrüder Borntraeger, 1924.) 4*s.* 9*d.*

ONE must congratulate German science on the large number of useful monographs which are constantly being published in Germany. When a branch of science has been advanced by independent original research in all parts of the world, it is highly desirable that every now and then we should be able

to review the progress made, and a monograph which collects all the threads together and sets them out as a more or less completed fabric not only achieves this but also gives an extremely pleasant form of reading to those working at the subject. The book before us is a good example of this type of literature, and is therefore to be welcomed.

The contents of the book are divided into two parts: Part I. deals with the observational facts and Part II. with the various explanations which have been offered from time to time of the electricity of thunderstorms. Throughout full references to the literature are given, and this alone makes the book of great value to the original worker in this field of science. Although the literature is now very large, we have not noticed any important omissions except in one case, namely, the omission to mention C. T. R. Wilson's outstanding paper, "Investigations on lightning discharges and on the electric field of thunderstorms," which appeared in the Philosophical Transactions in 1920. We feel sure that the author has not seen this paper, otherwise he could not have failed to quote many of the important results contained in it.

There is not much to say about the first part of the book, as it deals mainly with facts which are now fairly well known and generally accepted. Mohn's classification of thunderstorms as *Wärmegewitter* and *Wirbelgewitter* is shown to be well founded. In *Wärmegewitter*, which are called heat-thunderstorms in Great Britain, the energy is derived from temperature instability in the vertical direction, generally produced by intense solar radiation warming up the lower layers faster than the ordinary processes of convexion and turbulence can distribute the heat to the upper strata, although a similar effect can be obtained when air passes over a relatively warm sea surface. In the second type, the energy is derived from warm and cold currents which are brought side by side, generally in consequence of the circulation associated with cyclones. The thunderstorms associated with "line-squalls" are typical of this class, but we have no special name by which to describe them in English.

Besides a fairly full discussion of the meteorology of thunderstorms, Part I. contains a description of the electrical conditions observed, together with short accounts of the different forms of electrical discharges.

While the first part is probably the most valuable, the second part will, we think, be read with the most interest by many physicists. In it Dr. Kähler reviews some of the explanations which have been put forward to account for the origin of the electricity in thunderstorms. To discuss all would of course be impossible, for they are literally legion. It is interesting to see the large number of physical processes which have been used at one time or another in theories which are now finally abandoned, at least by most meteorologists, if not by their authors. Amongst these are cosmical dust; electrical influence from the sun, moon, and stars supposed to be electrically charged; cathode rays from the sun; ultra-violet light from the sun acting on ice crystals; friction between water and ice; differential condensation on positive and negative ions, and absorption of negative ions by falling precipitation. At the present moment there remain only three physical processes which are considered worthy of serious consideration: (*a*) the separation of electricity which takes place when drops of water are broken up in the atmosphere; (*b*) a similar effect produced when solids are brought into contact and then rapidly separated, the electrification of dust being a good example; and (*c*) influence charges produced on the precipitation by the electrical field.

In 1909 the reviewer put forward the theory of thunderstorms based on (*a*), which he extended in 1915, making use of (*b*) to explain the electrical phenomena of snowstorms and of thunderstorms in which there is no liquid precipitation. He is still of the opinion that these two physical processes are able to account for all the electrical effects associated with atmospheric precipitation. Dr. Kähler will not go so far as this, but while admitting that both may play some part, he considers that the influence effect is the chief factor at work. Elster and Geitel were the first to suggest an effect due to influence charges, but Dr. Kähler is not satisfied with their scheme and puts forward a modification of his own. This, we think, is the weakest part of his book. The modification of Elster and Geitel's theory which he introduces unfortunately results in a process which can only reduce an existing field; surely a process of this kind is not likely to be the explanation of the high electrical fields which are associated with thunderstorms.

Before closing this review we should like to direct attention to a pleasing aspect of Dr. Kähler's writing. Instead of using the long involved sentences so characteristic of German writings, Dr. Kähler expresses himself in short clear sentences. The average length of the seventeen sentences on a page opened quite at random is only eighteen words. We do not know whether this would be commended by a German of literary taste, but it is certainly very welcome to non-German readers.

G. C. SIMPSON.

Our Bookshelf.

Plants Poisonous to Live Stock. By Harold C. Long. (Cambridge Agricultural Monographs.) Second edition, revised. Pp. vii+120. (Cambridge: At the University Press, 1924.) 8*s.* 6*d.* net.

THE second and revised edition of Mr. Long's book on plants poisonous to live stock contains on the whole but few alterations. There are, however, several additions in the description of individual species, ragwort and bracken in particular, and some minor alterations in the concluding chapter on the classification of poisons.

In the introduction, the poisoning of live stock is dealt with from various points of view. Different species of stock often appear to be affected quite differently by the same plant, and poisonous effects may also vary with the individuality and age of animals of the same species. Some plants do not lose their toxic properties on drying, and therefore cannot be safely fed even with hay. Some also are poisonous in all their parts, such as meadow saffron, whereas in others the toxicity is confined to one part only, such as the seed in corn cockle. Further, soil, climate and cultivation may affect the toxic properties of a given species.

Most of the plants described are British, but foreign species such as "Java" beans, which may be used in feeding stuffs, and some common garden shrubs are also included. Fungi, with the exception of ergot, are not dealt with, though the toxicity of darnel seeds is stated to be due to the presence of a symbiotic fungus. The species are described under their natural orders, examples of poisoning, the toxic principle, symptoms, and references to the bibliography at the end of the book being given in each case.

As in the previous edition, the author also deals with plants suspected of being poisonous, and those affecting milk or causing mechanical injury to animals.

Theoretical Metallurgy. By R. S. Dean. Pp. vii+246. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1924.) 15*s.* net.

SCHENCK'S "Physikalische Chemie der Metalle," first published in 1909, broke new ground in metallurgical literature, since it described the application of physical chemistry, not only to the constitution of alloys, a task which had been attempted often, but also to the reactions of the smelting processes and to other technical metallurgical operations. The author of the present work translated Schenck's book some eleven years later, by which time some of the information was out-of-date. In place of preparing a second edition, he has preferred to re-write the book, whilst retaining the main features and many of the details of the original, including illustrations, so that the volume on opening has a familiar look. New subjects, including the structure of metallic crystals as revealed by X-rays, have been introduced, and the work now covers a field of great and general interest.

Unfortunately, the execution is not always equal to the design, and the text is very frequently inaccurate. Mathematical formulæ have suffered badly, as well as proper names, and although the number of references to papers is large, many of them seem to have been selected somewhat at random, investigations of equal or greater importance being overlooked. The sections which deal with steels are inaccurate, especially in regard to hardening. Many subjects receive such brief treatment that the student will derive little from reading those sections. It may be said that the experienced metallurgist will gain many useful hints from the reading of this book, which deals with interesting matters and is simply expressed, but he will need caution, whilst the inexperienced student is likely to be puzzled and confused by its numerous errors.

C. H. D.

The Deluged Civilization of the Caucasus Isthmus. By Prof. R. A. Fessenden. Pp. ix+139. (Boston, Mass.: T. J. Russell Print; London: F. and E. Stoneham, Ltd., 1923.) 25*s.* Large paper edition, 5 guineas.

PROF. FESSENDEN is an ardent advocate of the urgent necessity of archæological exploration in the Caucasus. While archæologists will agree that investigations in this area are likely to afford evidence which will help in the elucidation of a number of problems in the ethnology and archæology of prehistoric and early historic times, they will scarcely be prepared to endorse Prof. Fessenden's arguments, although they may wish him all success in his research. He holds that the Caucasus is the cradle of mankind; that it was there that the flood to which early records refer took place, and that it was thence that the races of mankind dispersed after their differentiation. By an elaborate analysis of Semitic, Egyptian and Greek traditions and of local names, he seeks to show that not only was this the site of Eden, but also that on his assumption it is possible to unravel the inconsistencies in the geography of the Greek legends and explain why, for example, the search for the lost pillars of Hercules towards the west was unsuccessful. The rise of water level in the Caspian area and the formation of an Atlantean Sea of 1800 miles breadth east of the Black Sea were responsible for the disappearance of the country to which the traditions referred and the consequent dislocation of the ancient geographical system. Prof. Fessenden has worked out his case in great detail and with considerable ingenuity. His arguments will be more convincing if, and when, he can produce archæological evidence to support them.

Fluxes and Slags in Metal Melting and Working: a General Discussion held by the Faraday Society and the Institute of Metals, with the Co-operation of the British Non-Ferrous Metals Research Association and the Institute of British Foundrymen, April 1924. Pp. 109-208. (London: Faraday Society, 1924.) 7*s.* 6*d.*

LIKE other general discussions arranged by the Faraday Society, this collection of papers on fluxes and slags brings together a most useful mass of facts known to a limited number of persons, and at the same time brings into relief the need for systematic investigation. In spite of the importance of fluxes in the working of non-ferrous metals, such knowledge of them as exists is almost entirely empirical, and very little has been done to determine the factors on which their efficiency

depends. The fact is brought out in several papers that the interfacial tension between slag and metal determines the separation of non-metallic inclusions, but only in the instance of the formation of metallic "fogs" when fused metals are in contact with their halogen salts have any actual determinations of this important factor been made. In welding and soldering, the efficiency depends on the wetting of the metal by the liquid, as well as on the solvent power of the flux for oxides, but neither the chemical nor the physical factor has been studied in any systematic way. Aluminium, the oxide of which is very difficult to eliminate, has received more attention than most metals, but much of the work remains merely qualitative. The papers, although technical in character, should be of interest to chemists and physicists who are concerned with problems of solubility and of surface tension. The importance of non-metallic inclusions is shown by a study of their influence on the resistance of metals to fatigue, and any work which would tend to lessen the frequency of these undesirable constituents would be of great value to the metallurgical industries.

Tulum: an Archæological Study of the East Coast of Yucatan. By S. K. Lothrop. (Publication No. 335.) Pp. vii+179+27 plates. (Washington: Carnegie Institution, 1924.) n.p.

IN this volume, Dr. Lothrop has placed on record the results of three expeditions of the Carnegie Institution of Washington to the east coast of Yucatan under the leadership of Dr. Sylvanus G. Morley in 1916, 1918, and 1922. The main objective was Tulum, the most important ruin in this region, but other sites also were visited. Dr. Lothrop, however, has not confined himself to the work of these expeditions, but aims at giving a complete account of present knowledge of the archæology of this area by summarising previous publications covering sites not visited on these occasions. The Maya culture of this part of Central America presents certain peculiarities in architecture, art, and religion which mark it off from the rest of Yucatan. Such are, for example, an absolutely new type of building—the shrine, and the sanctuary, the latter occurring in structures here called "palaces," as they appear to have served as residences rather than as temples. The frescoes, of which a large number have survived, are comparable with the drawings of the codices and are regarded by Dr. Lothrop as but little inferior to the Dresden codex which is the high-water mark of Maya art. Dr. Lothrop's detailed and lavishly illustrated account of this localised development of Maya civilisation, and his analysis of its cultural and ethnical affinities, is a contribution to American archæology which will rank high.

Outlines of Medical Zoology: with Special Reference to Laboratory and Field Diagnosis. By Prof. Robert W. Hegner, Prof. William W. Cort, and Francis M. Root. Pp. xv+175. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1923.) 11*s.* net.

THE "Outlines of Medical Zoology," which has recently been published by Prof. Hegner and his colleagues in the Johns Hopkins University, is a convenient little book for the use of medical men in the field, and for teachers of zoology in schools and universities where the economic applications of the science are included in the curriculum, but it is too concentrated for the elementary student and not sufficiently detailed in description for those who are seriously engaged in the study or the practice of the subjects. There is, perhaps, some danger lurking in these little books that the student, who has not much time to devote to it, may imagine that he has mastered the subject by learning off the tables and diagnoses by heart. They should only be used after or associated with a course of practical work in the laboratory accompanied by some further instruction in the morphology of the animals described.

We must acknowledge, however, the great care and skill with which the authors of the three parts—on protozoology, helminthology, and entomology—have condensed their wide knowledge and practical experience of their subjects, and recognise that the book will prove to be extremely valuable to many zoologists and medical men.

Theories of Memory. By Dr. Beatrice Edgell. Pp. 174. (Oxford: Clarendon Press; London: Oxford University Press, 1924.) 7*s.* 6*d.* net.

THIS admirable and valuable little book brings together in short compass, but in clear and comprehensible terms, the leading theories of memory, in particular the attempts to give precision and definition to the term "memory-image." Theories of memory, like theories of colour-vision, are baffling to the student in their numerical variety and diversity of principle. Miss Edgell reviews the biological theories of Hering, Butler, Semon, and Jennings, the behaviourist theory of J. B. Watson, and Lloyd Morgan's variation of it; she gives a general outline of philosophical treatment of the problem from Hobbes to the present day, discusses the views of Alexander, Bertrand Russell and Holt, criticises Bergson, and finally offers what she terms a psychological conception of retentiveness. Although it is a brief account of sometimes elaborate theories, the book bears throughout the mark of long and earnest study of the problem.

Exercises and Problems in Practical Physics: with Notes on the Theory. By G. N. Pingriff. (Bell's Natural Science Series.) Pp. xxii+199. (London: G. Bell and Sons, Ltd., 1924.) 4*s.*

MOST of the practical work, with the exception of the most elementary, likely to be carried out in school physics laboratories is covered by this little volume. It is no mere compilation of recipes for securing "results," although of course adequate directions are given for performing the experiments, some of which are refreshingly original while evidently practicable and instructive. Most valuable, however, are the accompanying comments, suggestions, and queries, which are well calculated to arouse the interest of the student and encourage him to think for himself. There is in addition a good deal of useful information of a practical nature which is evidently the fruit of a wide experience in teaching physics. In short, the book may be confidently recommended to student and teacher alike.

Letters to the Editor.

Absorption Spectrum and Constitution of Sulphur Vapour. Predissociation of Molecules.

THE vapour of sulphur consists of a mixture of S_8, S_6 and S_2 molecules; the quantities present vary with the pressure and temperature (Preuner, *Zeit. Phys. Chem.* 68, 1910).

We have studied the ultra-violet absorption spectrum of sulphur vapour at temperatures between 100° and 1000° and pressures from 0·5 to 53 mm. The temperature of the vapour in an absorption tube of clear quartz, 50 mm. long, with plane parallel optically clear windows, was always higher than that of a communicating magazine containing sulphur. Thus the temperature of the latter determined the total pressure of the vapour, whereas the temperature of the absorption tube gave the partial pressures of S_8, S_6, S_2.

The spectrum was photographed with a Hilger E_1 spectrograph (system Littrow), the source of light being a condensed high frequency (10^6 p. sec.) spark between copper electrodes under water (Victor Henri, "Études de Photochemie," 1919, Proc. Roy. Soc. 105, 662, 1924). The spectrum of this source is continuous down to 2300 Å, except for a series of weak water-bands at 3064 Å. The measurements of the lines are exact to 0·02-0·1 Å, depending on the type.

The following principal results were obtained.

At temperatures and pressures, where only S_8 and S_6 molecules are present ($t<250°$, $p<10$ mm.), a general absorption without any structure is observed, beginning at about 2700 Å and increasing continuously up to 2300 Å (limit of our measurements).

By raising the temperature in the absorption tube, so that the partial pressure of S_2 attains about 0·05 mm., five sharp groups of bands appear with fine structure at 2798, 2829, 2861, 2892, 2927 Å, and three or four broad bands at 2768, 2739, 2713 and 2678 Å.

At higher pressures of S_2, the number of groups of bands increases towards the red and ultra-violet end. For example, at 550° and 0·55 mm., where only S_2 exists, there is no trace of general absorption, and the spectrum consists of 18 groups of bands from 3114 to 2592 Å. At 550° and 20 mm. (also S_2 alone) we obtain 26 groups, and at 750° and 53 mm. (still S_2 alone) more bands towards the red appear, the last one being at 3700 Å.

The intensity and the number of these bands are always determined by the partial pressure of the S_2 molecules; the presence of S_8 and S_6 produces only a general absorption at the ultra-violet end of the spectrum.

This spectrum of the S_2 molecules can be divided into three very distinct portions; they appear in exactly the same positions under all conditions.

First portion: from 3700 *to* 2794·2 Å. *Bands with fine structure—the rotational movement of the molecule is quantified.* In this portion we obtain 14 groups of bands between 2794·2 and 3300 Å with a constant frequency interval of $\Delta\frac{1}{\lambda}=397$ cm.$^{-1}$, and 9 groups from 2950 to 3700 Å with an interval of $\Delta\frac{1}{\lambda}=700$ cm.$^{-1}$. Each group of bands consists of 3-6 series of bands and each band of this series is made up of numerous sharp lines. In every band the lines are very sharp and near together $\left(\Delta\frac{1}{\lambda}=0{\cdot}1\text{ Å}\right)$, specially at the origin of the Q branch (ν_0) and at the head of the R (positive) branch, the distance between ν_0 and the head being 20·9 cm.$^{-1}$; the head is towards the ultra-violet. This means that the moment of rotation of the activated molecule, I_1, is greater than that of the normal molecule, I_0.

All these groups and series of bands with their fine structures overlap each other and the resulting aspect of the spectrum is very puzzling. In this portion of the spectrum there are more than 5000 fine absorption lines.

We have systematically studied the spectrum while slowly increasing the pressure of S_2. We were thus enabled to arrive at a successive development of it. The bands appear in a regular order and the fine structure of each band can be analysed. At the first appearance of a band its structure is absolutely classical, formed of three branches R, P, Q. At higher pressures the same band gets very complicated owing to the overlapping with the next one and by the appearance of other branches R′, P′, Q′.

By studying the bands at the lowest pressures at which they appear, we found that the lines could be distributed into three branches:

$$R(m):\nu=\nu_0+c_1(2m+1)+c_2m^2$$ positive branch $m\to m+1$

$$P(m):\nu=\nu_0-c_1(2m-1)+c_2m^2$$ negative ,, $m\to m-1$

$$Q(m):\nu=\nu_0+c_2m^2$$ zero ,, $m\to m$

with

$$c_1=\frac{h}{8\pi^2cI_1}=2\text{ cm.}^{-1},\quad c_2=\frac{h}{8\pi^2c}\left(\frac{1}{I_1}-\frac{1}{I_0}\right)=-0{\cdot}2\text{ cm.}^{-1}.$$

This gives for the moment of rotation of the normal molecule of S_2, $I_0=12{\cdot}6\times10^{-40}$, and for the activated one, $I_1=13{\cdot}8\times10^{-40}$. The distance between the nuclei of the two S atoms is therefore 0·7 Å in the normal and 0·73 Å in the activated molecule of S_2.

Second portion: from 2794·2 *to* 2592 Å. *Narrow continuous bands without fine structure.* Below 2794·4 Å the absorption spectrum of the S_2 molecules changes abruptly. The fine structure disappears entirely, the absorption spectrum consists of 8 groups of bands with a frequency interval between the groups of 360 cm.$^{-1}$. Each group consists of about 20 narrow bands having a width of 1 to 2 Å; these bands are absolutely continuous, containing no sharp lines. *This means the disappearance of the quantified rotation of the* S_2 *molecule,* and is a special case of a general result observed by one of us for many different molecules (Proc. Roy. Soc. 105, 662, 1924).

Third portion: from 2592 *to* 2475 Å. *Broad continuous bands.* At 2592 Å we observe a new change in the absorption spectrum. The narrow bands disappear abruptly and we obtain about 6 broad bands (width 15 Å) with an interval of 300 cm.$^{-1}$.

The analysis of the absorption spectrum shows two abrupt changes in the structure of the S_2 molecule: the first one at 2794·2 Å, corresponding to an increase in the internal energy of 102100 cal. p. gm. mol., thus causing a decrease of the frequency interval of oscillation of the two S atoms from 397 to 360 cm.$^{-1}$. This proves that the distance between the two S atoms in the S_2 molecule increases, which means that the bonds are weakened, the rotation of the molecule is *not* quantified. It is important to note that in this case, where the molecule absorbs rays < 2794 Å, its chemical activity is increased, as results from the interesting experiments of Norrish and Rideal, which we propose to follow in further detail.

The second change of the S_2 molecule at 2592 Å corresponds to an increase of the internal energy of 110000 cal. = 4·77 volts. It is very interesting to note that this limit corresponds exactly to the resonance potential of sulphur vapour 4·78 volts = 110400 cal. = 2582 Å (Foote and Mohler). This shows that by increasing the internal energy by 110000 cal. the valency electrons jump into higher orbits. The vibration frequency of the atoms is still more decreased (300 cm.$^{-1}$), the distance of the nuclei in the S_2 molecule is therefore still larger than in the foregoing case.

These interesting results obtained for the sulphur molecule lead us to a general discussion of different kinds of transformations of any given molecule. We know by the electronic impacts that at a certain minimum potential the impacts are no longer elastic; this occurs at the resonance potential of the molecule. It means that certain electrons jump from the normal orbit into the next one. But now we see that before this state is reached the molecule can be modified in its internal structure: the atoms are driven apart, the bonds are weakened, the molecule becomes more reactive, and the rotational movements are no longer quantified. This first modification is a preliminary preparation of the molecule for its total dissociation, and it is necessary to introduce a new term for this change. We propose to denote it by the term *predissociation* of the molecule.

For each molecule we can distinguish, therefore, the following successive states: *normal*, *predissociated*, *resonance*, *ionised*, and finally the *dissociation* of the molecule. In each of these states the molecule can be activated. By studying the absorption spectra of vapours we determine the limits of these different states of the molecules.

Constant Differential Growth-ratios and their Significance.

A STUDY of the growth of the abdomen in the shore-crab *Carcinus maenas* (Huxley and Richards, unpublished) showed that whereas in the male the ratio *abdomen-breadth : carapace-breadth* remained constant, in the female it increased continuously during the whole of post-larval life.

Similar types of growth during the whole or part of life have been frequently recorded. Pézard (1918) has styled the growth of such an organ *heterogonic*, Champy (1924) *disharmonic*, as opposed to isogonic and harmonic respectively.

It seemed desirable to investigate this form of growth in a case where accurate weight-measurements were available: accordingly, advantage was taken of a visit to the United States to study the growth of the chelæ of Fiddler-crabs at the Marine Biological Laboratory, Wood's Hole. As is well known, the chelæ of females in these animals are small and equal throughout life, while those of males are unequal, one being similar to the female's, while the other is much enlarged. Morgan (1923 and 1924) has recently given us much information as to the time at and mode in which this asymmetry is determined.

The weights of whole animals of every size, and of their autotomised chelæ, were taken in *Uca* (*Gelasimus*) *pugnax*. The female and small male chelæ remain throughout life equal to ±2 per cent. of total weight.

For the large male chelæ, some 400 specimens were weighed, and divided into 25 classes by total weight. Let y = weight of large chela, w = total weight, $x = w - y$. It was then found that when $\log y$ was plotted against $\log x$, a remarkably straight line was obtained:—

$$\log y = k \log x + \log b,$$

where k and b are constants, $k > 1$, $b < 1$.

This was empirically established for total weights of 60 mgm. to more than 3.5 gm., and it can be deduced satisfactorily that it holds from the moment heterogonic chela-growth begins, which is at about 6-8 mgm. total weight.

The only complication lies in the fact that the slope of the line changes at a point corresponding to about 30 per cent. of maximum total weight, k here decreasing slightly to a new value, but remaining > 1. This change is probably coincident with sexual maturity, and would then be explicable through the gonad making a greater drain on the food-supply.

The simplest mathematical expression of the facts is $y = bx^k$. This implies that if during any given period, p is the fractional increase of x (total weight less chela), then that of the large chela in the same time is p^k. This would receive a biological explanation if the rate of cell-division were greater in the large chela than in the rest of the body throughout life, the two rates being as $k : 1$.

Since the *relative* growth-rates of organ and rest of body thus remain constant during long periods, I propose the term *Constant Differential Growth-ratio* for the phenomenon. Where the constancy of the ratio has not yet been ascertained, it is best to retain *heterogonic* as a more general term.

These facts have various corollaries: (1) The development of secondary sex-characters in Crustacea need stand in no relation with the gonad, or at least to maturity. (2) The male Fiddler-crab and the female Carcinus (and many other Crustacea) have *no definitive form*, their shape, as determined by the proportion of their parts, being a function of their absolute size. Thus even for purely morphological and systematic purposes, it will be needful to take measurements on large series of specimens, and to determine k in the above formula as one of the more important distinguishing marks of the species.

(3) Finally, we have the corollary, pointed out by Geoffrey Smith in 1905, that if this type of developmental mechanism holds throughout a group for any organ, the absolutely larger species of the group should possess this organ of relatively larger size than do the smaller. This relation has been shown to exist in Stag-beetles and many other Coleoptera, in Crustacea, and in Ungulata (G. Smith, 1905, Champy, 1924, etc.). It was tested out by us quantitatively on two species of Uca, with the following results:

	Uca pugnax.	*Uca minax.*
Maximum total weight	3·6 gm.	17·8 gm.
k, 1st period	1·61 – 1·64	?
k, 2nd period	1·32 – 1·35	1·58 – 1·66
Maximum ratio $y : x$, per cent.	65 per cent.	77 per cent.

Only a few *U. minax* were available, and those clearly all in the 2nd period.

It is interesting to find k near to 1·5 in all cases. If it were exactly 1·5, the surface of the chela would be increasing in direct proportion to the volume of the rest of the body. It remains to be seen whether this is a mere coincidence or not.

The greater absolute size attained by *U. minax* led to the largest large chela in this species attaining a

relative weight 12 per cent. greater than in the small *U. pugnax*. Our expectations are thus fulfilled.

This has an important bearing on evolutionary and genetic theory. If (1) a mechanism for the heterogonic development of any character occurs throughout a group, and (2) the evolution of the group has been on the whole from small to large size, we shall get apparent orthogenesis of the character. There is proof of (1) in the antlers of Cervidæ (Rörig, 1901, Champy, 1924), and strong probability of it for all horns and other bony excrescences in mammals. As regards (2), this size-increase has occurred in almost every group of mammals, and is probably to be accounted for by the biological advantage conferred (up to a certain limit) by increased size.

If so, then the apparent orthogenesis of horns, etc., in mammals, especially urged for Titanotheria by Osborn (1918, etc.), is no true orthogenesis at all, in the sense that it is not caused by determinate variation of the hereditary constitution. On the contrary, it would be automatically brought about by the increase of absolute size of the whole animal (which in its turn is probably effected by natural selection plus random variation, and not by determinate variation), together with the existence of the same type of developmental mechanism for horn-growth throughout the group. That is, orthogenesis would mean nothing else but directional evolution, and had better be dropped in favour of that term, because its past use has often implied directional evolution which is also determinate owing to internal causes.

Sturtevant (1924) has recently expressed somewhat similar ideas, but in a very general way, and without any numerical data. Champy (1924) has expressed still more similar views, but again without accurate measurements on large numbers of animals, which, in view of the degree of normal variability, are necessary to establish any quantitative law for the growth of heterogonic organs.

Full details will be published in due course. I have to thank Dr. Lillie for the hospitality of the laboratory at Wood's Hole, Mr. F. N. Ratcliffe for assistance in the work, and the Royal Society for a grant.

Theories of Growth and Senescence.

IN the thoughtful and stimulating criticism of my book, "The Chemical Basis of Growth and Senescence," which appeared under the above title in NATURE of August 23, there occur one or two statements in which my actual views are not correctly represented, due, no doubt, to inadequacy of expression upon my part. I desire to seize the opportunity created by the appearance of this criticism to express my views more clearly without entering into a detailed discussion of numerous other matters in which the reviewer and I chance, for the moment, to differ in opinion.

The reviewer states, "The evidence that the autocatalyst [of growth] is soluble and diffusible is based, not upon any evidence from the higher animals but solely on studies of infusoria, bacteria and yeasts." This is not quite the case even if we confine our attention to the evidence contained in the book and disregard that which, since its publication, has appeared elsewhere. It was inferred that the autocatalyst of growth must be soluble and diffusible in the higher animals, as well as in protozoa, for the following reasons :—(1) That Wildiers and others have found growth-accelerating agents in extracts prepared from a diversity of tissues, and these agents resemble in their properties (thermostability and solubilities) and behaviour (effects upon cell-multiplication) the accelerative agents which may similarly be extracted from yeasts and infusoria themselves. (2) That the fusion of the separate autocatalytic syntheses occurring in all the cells of the body into an autocatalysed curve representing the growth of the organism as a whole, could not possibly occur if all of the separate syntheses pursued their own independent paths. They must therefore be regulated by a product which is interchangeable between the various cells comprising the tissues of a higher organism. To be interchangeable between widely separated cells this product must to some extent, however slight, possess properties equivalent to solubility and diffusibility.

Since the publication of my book, however, this deduction has received direct experimental confirmation from two independent sources. A. Fischer (*Journ. of Experimental Medicine*, vol. 38, p. 667) has shown that contiguous fibroblasts in a circumscribed volume of culture medium mutually accelerate each other's multiplication, and M. T. Burrows has shown that the same phenomenon occurs in cultures of cancer-cells (*Southern Medical Journal*, April, 1924). The principle of allelocatalysis has thus been shown to apply to vertebrate tissue-cells no less than to cultures of yeasts or infusoria. In consequence of this effect the growth of the organism as a whole displays the time-relations of an autocatalysed reaction, nor does this interpretation of the curve of growth imply, as the reviewer supposes, that the syntheses which underlie and determine the rate of growth must necessarily occur in homogeneous solution, for, as Nernst has shown, reactions which occur at the surface of two immiscible phases may display the same time-relations as reactions which occur in homogeneous solution.

The reviewer very properly directs attention to the omission of any reference in my book to the important work of Dr. E. J. Allen on the growth of marine algæ (Jour. Marine Biol. Assoc., vol. 10, 1914, p. 417). My attention was directed to Dr. Allen's work, unfortunately too late to permit its inclusion in the book. Naturally, I would not advertently have omitted reference to experiments which afford such a remarkable illustration of the widespread occurrence and importance of growth-accelerating agents.

I do not regard regeneration as "an irreversible process of senescence," and am at a loss to understand how the reviewer could possibly have formed such an impression. I assert that lost parts tend to be replaced by a more (physiologically) differentiated type of tissue and that such growth of tissue must increase in some measure the senescence of the organism as a whole (that is, abbreviate its "expectation of life"). This, however, is very far from instituting an identification of regeneration and senescence. In regard to the nature of the stimulus which starts growth after injury, I have suggested that it may be in part the local increase of nutrient level. Obviously, the nutrient level in a circulating medium, such as blood, must be quickly equalised all over the body, but in the pericellular fluids, which really constitute the nutrient medium inhabited by the cells, such equalisation must be relatively slow. The nutrient level in these fluids at any particular point will therefore be determined, on one hand by

the rate of supply from the circulating medium, and on the other by the rate of local consumption. The latter factor must obviously be reduced by the removal of normally adjacent cells by injury.

I am surprised to learn that I have treated Child's theory of rejuvenescence and senescence "with silent contempt." This was very far indeed from my intention, for, on the contrary, I regard this theory as the necessary complement of my own. My presentation of Child's opinions may have been inadequate, but it was not intentionally so, and I must absolutely decline to view Prof. Child as an "opponent," even if for no better reason than because his demonstration of the existence of metabolic gradients in the tissues of the metazoa is one of the most important pieces of evidence upon which I base my interpretation of differentiation. To put the matter upon a crudely quantitative basis, however, the fifteen citations from Child's publications which my book contains should surely have sufficed to protect me from this accusation.

I am glad to avail myself of this opportunity to clear up an obscurity to which the reviewer directs attention in his final criticism. He credits me with the statement that "variation always takes place by loss of characters," and I must admit that my phraseology is open to this one-sided interpretation. My meaning, however, was this:—Since every new type of tissue which appears during development does so as a result of physiological differentiation, *i.e.* the omission from the new cells of certain nuclear constituents, it follows that the appearance of a character which depends upon the development of a new type of tissue must occur in consequence of a tendency of the germ-plasm to become deficient. Such a mutant, which undergoes more extended development and differentiation than that which occurred in the parent-type, must be recessive. Any mutation involving premature *arrest* of development and differentiation must, for the converse reason, be dominant. In my desire to make clear the first consequence of my hypothesis I omitted to elaborate adequately the second, which, indeed, appeared to me to be obviously implied in the first. Thus both dominant and recessive varieties may arise, but those which represent a positive gain of a new type of tissue cell must be recessive. Of course in any individual example, in the present state of our knowledge, it may be a very difficult matter indeed to decide whether a given external character is really attributable to the development of a new type of tissue or to the non-development of tissue-cells which occur in the parent-type, for, in general, the omission of any particular stage of differentiation must create opportunities for the development of other cells which would normally be denied to them.

If, however, devolution of the nucleo-cytoplasmic ratio ("physiological differentiation") can occur, it will, since this affords the only means by which the constituent cells of the organism can continue to propagate themselves, and the selection of lower nuclear ratios, to which the struggle for existence among the cells must lead, will ensure the appearance and multiplication of cells possessing lower nuclear ratios, if that is possible. Since "cellular selection" is always operating in a direction favourable to their appearance, new varieties which are recessive should, in the terms of this hypothesis, appear much more frequently than new varieties which are dominant, and the facts, as the reviewer himself admits, are absolutely in accordance with the theory.

The Word "Scientist" or its Substitute.

IT will probably be agreed that language was made for man as a means of expressing his thoughts and feelings. It would seem to follow that the first duty of a word (or, to be precise, a noun) is to express an object or an idea definitely and uniquely. When this duty is fulfilled, the demands of philology and beauty might, and indeed should, be considered, but their importance is clearly secondary, except perhaps in poetry of a certain type.

It does not appear that any of the suggested alternatives to the word "scientist" fulfil this primary requirement. "Man of science" is anything but definite and unique. It might mean a Robot, or any of a large number of unintelligible things (cf. "men of stone," "man of sorrows," "men of Athens," "man of mark," etc.), the preposition "of" being perhaps the most indefinite word in the language. "Natural philosopher" is no better. It does not tell us whether it is the philosophy or the philosopher that is natural, nor does it distinguish between the various meanings of the word "natural," to say nothing of the word "philosopher." Nor is "rationalist" satisfactory. It includes, for example, both Galileo and his opponents, and totally fails to distinguish between the kinds of data on which they exercised their reason.

Sir Ray Lankester's suggestion, that "*we* must be content to be anatomists, zoologists," etc., does not seem to be practicable. If the collective word "science" is necessary, then, on precisely the same grounds, a collective word equivalent to "scientist" is necessary also. The fact that these collective words are necessary is exemplified by the front page of NATURE, where the paper is described as "A weekly illustrated Journal of Science"—not "A weekly illustrated Journal of Anatomy, Zoology, etc." Unless a collective word is used for the investigator, how, for example, is Dr. Jeans to be described? Are we to call him an astronomer-mathematician-physicist, placing the terms in alphabetical order to avoid suspicion of partiality and praying devoutly the while that he do not undertake psychical research?

It would appear that a word equivalent to "scientist" is necessary, and until one is suggested which expresses equally definitely and uniquely the idea implied, I cannot see any justification for rejecting "scientist" in the columns of NATURE or elsewhere. Since clear expression is so intimately bound up with clear thought, the question has more than an æsthetic interest.

HERBERT DINGLE.
Imperial College of Science and Technology,
South Kensington,
December 9.

MAY I offer some general observations in connexion with the question as to the use of the word "scientist."

Language appears to be our way of expressing ideas by posture and gesture of the tongue, lips, etc. These gestures are recognised by the musical effects produced when air is blown through the vocal cavities as they perform their symbolic movements.

The perfect language would be one in which all ideas were expressed by the simplest series of gestures, and in which each separate gesture or series of gestures always bore one and the same meaning.

Up to the present time, language has grown up without conscious human guidance; it is therefore full of inconsistencies, ambiguities, omissions, and redundances.

From this point of view, it would be well to review

our forms of speech wherever the present words appear to fail in their purpose.

"-ist" is a concise termination (my only objection to it would be that it contains the unvoiced hiss "s," and the unvoiced explosion "t," which are both inartistic and phonetically ineffective sounds). It is shorter than "-ian" (as in mechanician, etc.), and it already bears a different meaning from "-er" as in runner, singer, etc.

I would therefore plead not only for "scientist" as being a concise and expressive word for one who is skilled in science, but also would go further and suggest the more general use of the termination "-ist" to denote one who is an expert on the theory as well as the practice of the art which he practises.

Thus, we might have *chemicist* (and distinguish him from the "chemist and druggist," and *electrist* to run in parallel with "physicist." If "maths" has come to stay, "mathist" would be an obvious improvement on "mathematician."

There are good reasons why an art, so important to human welfare as language, *should* be rationally developed and improved for human use; it should not be compelled to remain for ever in the neolithic stage.

R. A. S. PAGET.

East India House,

December 3.

YOU cannot help it; scientist is an established term, and you can no more suppress it than you can suppress bigamist. But if NATURE maintains its policy on the subject, I am sure we shall not grudge the Editor this little tyranny.

My belief is that objection comes almost entirely from the fact that the word scientist is cacophonous. If the word had been as well lubricated as its near neighbour "sciolist" I am convinced that we should never have heard any serious objection to it, unless perhaps Fate by some caprice had briefed Sir Ray Lankester for the prosecution.

There are already "Rationalists." I was taken to see one not long since, and I should like to be there when Sir Ray Lankester was seeing him. Natural philosophy is still physics in Scotland, and "naturalists" are everywhere students of natural history (sometimes nowadays confused with natural science). A real object of pity is the man who still has to indicate his calling to the public by styling himself

A CHEMIST.

Very Intense Magnetic Fields.

IN previous letters which appeared in the issues of NATURE for April 19 and September 20 respectively, I gave some details of a method for producing very intense magnetic fields.

I now give in Fig. 1 an oscillogram of the condenser current discharge through a solenoid wound with 25 turns per cm. length. The scale of this oscillogram is such that the second peak represents a current of 23,100 amperes in the solenoid winding. It follows, therefore, that the intensity of the magnetic field at the central part of the solenoid core was 730,000 gauss.

Apart from the very high value of the magnetic intensity thus obtained, an examination of the oscillogram of Fig. 1 yields some further very interesting results:

(i.) The frequency of the discharge current as given by the first half-wave of the current is very much higher than that of the rest of the wave. The frequency of the first half-wave about corresponds to the value as calculated from the static constants of the circuit.

(ii.) The current represented by the second peak is greater than that denoted by the first peak.

(iii.) The current values actually obtained are very much greater than those calculated from the constants of the circuit.

A full explanation of these effects is not yet clear. There is one factor, however, which has an important bearing on the phenomena, namely: The intense mechanical force developed between the neighbouring turns of the solenoid causes them to move relatively to each other, and in this way a back e.m.f.

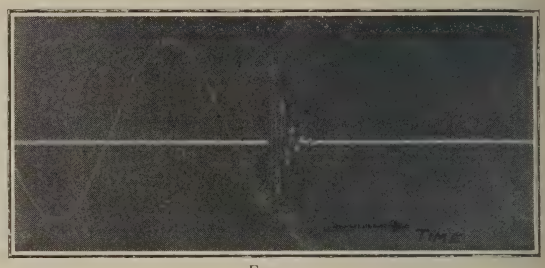

FIG. 1.

is induced in the solenoid winding which is equivalent to a change in the static constants of the circuit. The large wave shown in the oscillogram is a 50 frequency wave.

Magnetic fields of an intensity of 1,400,000 gauss have been obtained already by the method described, and there is definite evidence that the magnetisation curve of steel is changed after having been subjected to these very intense fields.

Further modification of the apparatus is now being effected by means of which it is expected that magnetic fields of an intensity of about 10,000,000 gauss will shortly be available.

Chemical Reactions at High Pressures.

IT is generally recognised that under high pressures many chemical reactions which take place only slowly under ordinary conditions may be greatly accelerated, and new reactions, hitherto considered impossible, may reach a considerable velocity. This opens up a very interesting and important field of study, and there is little doubt that there may result many important industrial developments and even the creation of new industries. Before, however, the chemist can adequately discharge his functions in connexion with this work, it will be necessary for the engineer to provide him with the special tools which will be required in connexion with it. For example, new means will have to be found for the development and control of pressures of a much higher order than has hitherto been used. New methods for the handling of solids, liquids, and gases will have to be devised; heat interchange under new conditions will have to be studied. In fact, the technique of high pressure work generally will have to be developed.

May I suggest that, if Great Britain is to keep abreast of the advances which are being made in this field abroad, it is very necessary that the serious attention of our engineering schools and laboratories should be turned to the need of the chemist in this connexion.

Neanderthal Man and Grimaldi Man: their Rôle in the Evolution of Mankind.[1]

By Prof. RÉNÉ VERNEAU, Muséum national d'Histoire naturelle, Paris.

THE important discoveries in the domain of human palæontology which have been made in recent years, and those, far greater in number, which may be referred to the Neolithic period, have now made it possible for us to venture on an inquiry which seems to me not without interest. What, it may be asked, is the rôle that the nigritic element has played in the ethnology of the world in the past?

Wherever Neanderthal man occurs, he displays a remarkable homogeneity in character. It is no longer possible to regard him as physically or mentally diseased. He represents a primitive ethnic type which still retains a certain number of simian characters, as Schaafhausen and Huxley maintained, and as is acknowledged by all scientific workers of to-day who are free from prejudice. It is also incontrovertible, in my opinion, that Neanderthal man, taking his characters as a whole, can be brought into relation only with the nigritic group—a point which, I hold, it should not be difficult to demonstrate. But what is the rôle that he has played, and how great is its importance in the evolution of mankind? This is a point upon which there is complete disagreement among men of science. It is a question which appears to me to be sufficiently interesting to be discussed in some detail.

When it is admitted with Huxley, de Quatrefages, and Hamy, to mention a few only of those who have held this view, that there still exist in Australia representatives of the Neanderthal type who, however, in the course of ages, have undergone certain modifications under the influence of environment, the answer is simple. This type must have played a part of some note, since it has been able to perpetuate itself to this day in a country in which, as all agree, the environment has remained relatively stable. In Europe, so far as our present knowledge goes, the evidence for its existence is more difficult to follow. At the same time, de Quatrefages and Hamy held that certain characters observed in Neolithic crania and even in modern crania were atavistic manifestations of an ancestral state. On this view Neanderthal man should be regarded as one of our ancestors.

This theory, which is accepted by a number of anthropologists including myself, has been violently opposed by those who are unable to bring themselves to include in our ancestry a type which retained simian characters.

To-day, a whole school, which includes a number of eminent workers to whose knowledge and sincerity I render the fullest homage, and who for the most part call themselves evolutionists, maintains that Neanderthal man has bequeathed no single drop of his blood to modern man, and that *Homo Neanderthalensis* is a distinct species which has been replaced by *Homo sapiens*. To dispute a theory which is in the fashion is always an ungrateful task, especially when one appreciates the great merit of one's antagonists. Nevertheless, I may perhaps be permitted to set out the arguments of those who uphold these new ideas and the reasons which forbid me to agree.

[1] Translated from the Huxley Memorial Lecture for 1924 of the Royal Anthropological Institute, delivered on November 25.

The palæontologists, relying for their argument upon the extinction of various species of animals during the geological ages, maintain that man is no exception to the general rule. I agree without the slightest qualification that human beings are subject to the great laws which govern other forms of organic life. But we must discover which of these laws is responsible for the disappearance of those species which have become extinct. To me there can be no doubt that that law is the adaptation of the organism to the environment. When the environment undergoes profound modification, as was the case in past geological ages, the organism, being no longer in harmony with the new conditions of existence, which it is unable to modify and to which it cannot adapt itself, must perforce disappear. In the case of man, however, the facts must be looked at from a different point of view. Although it is true that from the beginning of the Quaternary, that is to say from that point of time from which we can follow up man with certainty, changes in the environment have taken place, they have not been so considerable as to make it impossible for man to adapt his organism to the new conditions. There is proof of this in the remains of man's handiwork which are found at every level. There is another consideration which is not taken into account: the emigration or extinction of the Pleistocene species, whether they belonged to the warm or the cold fauna, takes place in close relation to climatic conditions, against which man, even of the most primitive type, is able to struggle in virtue of his intellectual powers. It follows then that while man is to a certain degree subject to the influence of his environment, he is able through progressive adaptation to evade the violent shock which brings about the disappearance of other species.

Among those who receive new ideas with their eyes closed and attach more importance to words than to facts, there are some who may object—and this has actually happened to myself—that it is not proved that Neanderthal man was an intelligent being. Their doubts are raised by the nomenclature applied to primitive man—or, at least, to one of his branches, now said to be extinct—and to modern man, who is known as *Homo sapiens*. The term *sapiens* is quite inappropriate, as it is applicable only to moral or intellectual qualities, and there is no specific reason for applying it to *Homo sapiens* to the exclusion of *Homo Neanderthalensis*. As regards the moral qualities of the latter we can only advance pure hypotheses; but it is quite another matter in regard to his intelligence. Here I may leave the argument to one of the most eminent and at the same time one of the most firmly convinced upholders of the theory that *Neanderthalensis* became extinct at an early date, my learned colleague and friend, Prof. M. Boule. After having stated in his great work "Les Hommes fossiles" that certain backward peoples of the present day, whom nevertheless he classifies as *Homo sapiens*, are to be brought into relation with Neanderthal man, "if not from the point of view of physical characters, at least from the point of view of moral qualities" and by their mode of life, he adds, "the latter is already man, notwithstanding

the morphological inferiority of his brain, and is in no way the precursor of man, since we find mingled with his bones the implements of stone that he knew how to make and the ashes of the fires he knew how to light and how to tend. Already his actions are those of modern savages; and if naturalists, abandoning their usual practice, were to base their classification of the beings they study upon intellectual qualities, they would have no specific ground for a separate classification of Neanderthal man and modern man; while, as we have already seen, it would not be possible to refuse him this distinction on the ground of his physical characters."

That is how the question stands. *Homo sapiens* is not marked off from *Homo Neanderthalensis* by his intellectual qualities, as we might be led to suppose from the specific title which has been bestowed upon him. It is by his physical characters that he is separated from modern man, even in the case of peoples of the most primitive type. This is well shown by an examination of the cranial characters of Neanderthal man and comparison with modern types such as Australian, Bushman, etc.

From what has been said, it emerges that there is no character which has been observed in *Homo Neanderthalensis* which is not to be found in modern man, though principally among the nigritic races. But, as Prof. Boule has very rightly said, it is not the existence of an isolated character which is of interest to us from this point of view. "It is the presence, the conjunction, the accumulation of these characters in *each* of a whole series of crania" which has value. Each skull in the Australian series of this type with which I have dealt presents such an accumulation of characters of the Neanderthal race that it is impossible for me not to accept a close relationship between the two groups. To my mind, the Neanderthaloid Australian skulls prove that the Neanderthal race has not "died out without leaving any descendants." It follows that this nigritic race, which played an important part in antiquity, has also made its influence felt in man of to-day.

But if the Neanderthal type [Rhodesian man] persisted in Africa, why could he not have persisted in Australia, and why should he not have submitted there to the influence of environment as he did in Rhodesia? Could he not have been modified as Rhodesian man was in some degree when he acquired the upright attitude? When we consider the enormous distance in space and time which separates the Neanderthaloid Australians from our Mousterians, it is difficult to conceive that the type could have perpetuated itself in New Holland without modification. This would be a denial of the influence of environment which I could not accept.

On the other hand, it may be argued that, judging by its flora and archaic fauna, the Australian environment does not appear to have undergone any great change. It is this which explains precisely how it is that the characters of the southern tribes have only suffered some attenuation. To maintain that the conditions of existence of these natives have remained absolutely stable, and to hold that the Australians have not progressed, is an untenable hypothesis. The main characteristics of the material culture of the Australians show that this is not the case. All this denotes that, however backward they may be, the Australians have evolved and they no longer stand where stood the Mousterians in Europe. It would not be credible that while their intelligence developed their physical characters remained immutable. But their evolution has been very slow and they have preserved a group of Neanderthal characters sufficiently well-marked to lead me to regard them, as Prof. Boule has done elsewhere, as derived from the same source as *Homo Neanderthalensis*. These characters are beyond question nigritic, and it is difficult to refuse to admit that this nigritic element, which played a part in Europe in the first part of the Quaternary age, has not bequeathed its blood to modern man, notably the South Australian and apparently in a lesser degree to other Melanesians.

Let us now see if traces of it can still be found in Europe at the present day. There have been found on many occasions in prehistoric, historic, and modern burials, skulls which reproduce in part the characters of the ancient fossil race of which we are speaking. There are specimens in many museums and since 1882 the authors of "Crania Ethnica" have described a number of examples. Additions are being made to these observations continually. In 1914, for example, Verworn recorded two skeletons found at Obercassel, near Bonn, in a hearth of the Reindeer age. He noted that they presented certain resemblances to the races of Cro-Magnon and Chancelade, and, in addition, showed Neanderthal characters. Beside this nigritic bestial type there is another, more highly developed, representatives of which are to be found dating from the Quaternary epoch. This is the negro type which I have called the race of Grimaldi, as the first examples were found near the Italian frontier in the territory of a commune bearing this name. The physical characters of Grimaldi man show close resemblances to the negro type.

In the presence of so many characters which are frankly nigritic, and of which some indeed recall those of *Homo Neanderthalensis*, it must be recognised that, at one point in the Quaternary period, negroid individuals lived in Europe. It may, however, be asked whether the two subjects from Baoussé Roussé were not negroes who arrived there accidentally and disappeared without exercising any influence in Europe. My researches on this problem have led me to discover in several museums in Southern Italy modern crania with characters which incontestably recall those of the Grimaldi race. I have even found two living subjects who came from the Graian Alps, where it is difficult to believe that any negro could have penetrated in recent times; these showed a number of the cephalic characters of the Baoussé Roussé negroids. When once attention was directed to this point observations multiplied. Skeletal remains of negroids have been found in collections from France, Switzerland, Italy, and North Africa. Some dated from the Upper Palæolithic (a series of crania from the rock shelters of La Mouillah on the frontier of Western Algeria), others from the shell heaps of Tebessa, of which the age is disputed, and others from the Lower Neolithic of the Province of Oran. In North Africa, the negroid element must have formed the ethnic substratum of the whole of the Berber country. In Europe we find it in the Neolithic age in Brittany, in Switzerland, in Illyria, the Balkans, etc.; in the Bronze and early Iron ages in

Switzerland, in Southern Italy, and so on. It is plausible to attribute to atavism the prognathism, often very pronounced, and the retreating chin which is to be observed to-day among certain individuals who do not otherwise exhibit nigritic characteristics, either in the hair or in the coloration of the skin. As I wrote in 1906, "since we still find to-day so many traces of an ethnic type with characters which recall those which I have observed in the Grimaldi race, we are compelled to believe that this race was formerly represented among us by a whole group." I might add, however, that the same type must have been equally strongly represented in North Africa.

To sum up, the division of mankind into two entirely distinct species, *Homo Neanderthalensis* and *Homo sapiens*, the first long extinct and leaving no trace behind, does not appear to me to be justified. The Neanderthaloid characters of the Australians indicate a close relationship with our Mousterian man, while on the other hand, certain features in Neolithic or modern skulls found in Europe are to be explained as due to atavism. The race of Neanderthal, thoroughly nigritic in type, has continued to play its part among us, as it has in Africa, Australia, and elsewhere. Observations made on the Pleistocene skeletons of Wadjak and on remains from the mounds of Nebraska lead me to believe that the same element has entered into the ethnology of Java and the New World.

In the case of Grimaldi man, no doubt is possible. The traces can be followed in Europe almost step by step from Aurignacian times to our own day. In North Africa its existence is equally apparent though it may not be possible to fix the date of its appearance with precision. Another nigritic element, the Papuan, has just been noted in Tonkin by M. Mansuy on sites which take us back to a Neolithic period of very high antiquity. In 1879, A. de Quatrefages observed similar characters in a fossil cranium from a cave near Lagoa Santa in Brazil. P. Rivet has found the type represented in some abundance in the rock-shelters of Paltacalo in Ecuador; and it appears among the Pericues, an extinct tribe of Lower California, which H. ten Kate had already recognised to be clearly related to the Melanesians. I myself have pointed out the existence of this strongly marked type among the Tunebos of Colombia. From California to the extreme south of America the nigritic element has played a part of sufficient importance to leave its traces everywhere.

From all these facts I conclude that mankind in the beginning was represented by one or more nigritic types of marked bestiality and retaining several simian characteristics. These primitive elements have evolved and have given rise to the great negro stocks of to-day, the African and the Melanesian. This evolution has been progressive. We have a proof, in my opinion, in the intermediate types found at Talgai and Wadjak. These intermediate types, while evolving in some degree, have perpetuated themselves to the present day in special conditions, as, for example, among the non-Neanderthaloid Australians and the New Caledonians. Our Grimaldi negroids are too far removed from Neanderthal man to allow us to suppose that they are immediately descended from him, especially if the interval separating them is relatively small. Where could this type have become established? I do not know. On *a priori* grounds we think of North Africa; but the negroids of North Africa appear to be more recent than those of Baoussé-Roussé.

The conclusions which emerge may be summed up in a few lines:

(1) Primitive man exhibited simian characters pointing to relationship with the anthropoids. This archaic type has not become extinct; it has evolved in accordance with its environment. Traces of it occur very sparsely in Europe, but are readily discernible in South Australia.

(2) This primitive type was followed by a more developed type in which the simian characters have gradually disappeared, but in which the nigritic characters are retained in a marked degree. Although it plays only a very insignificant part among ourselves, this is not the case in other parts of the world.

(3) Recent discoveries lead us to suppose that a nigritic element has everywhere preceded the yellow and white races.

In truth, there are too many gaps in our knowledge for it to be possible to follow step by step the evolution of man in time and space. The links which are needed to establish the filiation of the races are missing. Yet it seems to me that my view of the question is more nearly in accord with the facts than that which accepts a gap between early man and man of to-day.

The Biological Action of Light.

THE beneficial action of a change of climate, especially when a sunny place is chosen, is well known: why the change is so frequently more effective than other therapeutic methods is a question which has only recently been investigated scientifically—one of the many examples of the lag in the acquirement of scientific knowledge behind popular opinion. Apart from the mental effects of a change of scene, benefit may be derived from both the cooling power of the air and also the incidence upon the body of the sun's rays. C. Lee Pattison (*Lancet*, October 18, 1924) has recently given an account of the therapeutical effects of ultra-violet radiations, while C. Dorno (*Naturwissenschaftliche Umschau d. Chem. Zeitung*, October 1924) has considered the subject more from the physical aspect. The effects of the different parts of the spectrum are not the same, the ultra-violet rays being the most active therapeutically. They are present in the atmosphere to a much greater amount, relatively to the infra-red heat rays, in summer as compared to winter, but their activity is confined to the superficial layers of the skin, since they have only a low penetrating power. It must be remembered also that these rays are largely absorbed by glass, and therefore exposure must be made in the open air or directly to a source of ultra-violet light.

It appears possible that rays of a shorter wave-length than 290 $\mu\mu$, which do not occur in the solar radiation, may be still more effective than the latter. The skin pigment absorbs chiefly the visible yellow and green rays, with the production of heat, which is then radiated outwards by the skin, while the red and short

infra-red penetrate still more deeply. In this way, in a cold atmosphere, the body temperature is higher in the deeper parts but falls, from radiation from the skin, towards the surface. If this radiation from the skin is mostly prevented, as in a warm damp tropical atmosphere, the surface of the body tends to have a higher temperature than the deeper portions : hence arises the enervating influence of the tropics, whilst in a colder (and sunny) climate the conditions are invigorating.

The increased loss of heat from the skin in a cool atmosphere, as at a high altitude, appears to be greater than the increase in the temperature from the absorption of light and heat rays, since, as Leonard Hill has shown, the metabolism of the body at rest is increased from 50 to 100 per cent. under these conditions, and to this increase is due a great deal of the benefit which ensues. Further, a cool atmosphere is usually drier than a warm one, and this promotes an increase in the evaporation of aqueous vapour from the lungs, with a resultant increase in the flow of fluid through the respiratory membranes, thus aiding in the healing of any lesions of the respiratory system which may be present.

Apart from alterations in metabolism and temperature, various changes in the constitution of the body under the influence of light have been described. Thus, there is an increase in the bactericidal power of the blood : whilst the formation of the blood platelets has been found to be stimulated (Cramer and Drew). The now well-known beneficial effect of sunlight in rickets appears to be due to a mobilisation of any vitamin A which is still in the body, without, however, causing its synthesis : light, therefore, enables normal growth to continue on diets which are relatively deficient in vitamin A. The body changes in rickets depend on a disturbance in the metabolism of calcium and phosphorus and are accompanied by a reduction in the amount of inorganic phosphorus in the blood. The addition of vitamin A to the food or exposure to light, especially ultra-violet rays, produces an increase in the blood phosphorus together with increased retention of this element and calcium (Orr, *et al.*). It must, however, be remembered that light, like other therapeutic agents, should be used with caution, since in certain cases it may produce a depressing effect, impairing, instead of strengthening, the body's resistance.

Obituary.

Prof. J. I. Hunter.

BY the sudden death of Dr. John Irvine Hunter, Challis professor of anatomy in the University of Sydney, while on a visit to England, British anatomy has lost its youngest and most promising recruit. In our issue of December 6, p. 842, it was stated that a course of free public lectures on "The Anatomy and Physiology of the Sympathetic Innervation of the Striated Muscle" would be given at University College at five o'clock on December 8, 10, and 12, by Prof. Hunter. On Monday, December 8, when an audience assembled, it was Prof. Elliot Smith's painful duty to announce that Prof. Hunter had fallen ill on Saturday and was then lying in University College Hospital. Typhoid fever was diagnosed, from which he had evidently suffered for some time before giving in. On Wednesday, December 10, the date on which his second lecture was due, he sank and died from heart failure at the early age of twenty-seven, having occupied his chair for only three brief but brilliant years, leaving a young widow and a wide circle of friends in England and Australia to mourn the loss which had so suddenly and so unexpectedly overtaken them. He was buried in North Finchley cemetery on Friday, December 12, after a brief but impressive service in St. Pancras church.

It is given to few men to be elected to a senior chair in their twenty-third year and in four short years to establish a reputation which places them amongst the leaders of their chosen profession. When we seek to discover how success came to Prof. Hunter so early and so rapidly, we recognise that credit must be given to his master—Prof. J. T. Wilson. On relinquishing the Challis chair of anatomy in the University of Sydney on his appointment to the chair of anatomy in the University of Cambridge in 1920, Prof. Wilson urged the appointment of Dr. Hunter as his successor—although the latter had only just completed his medical studies. Dr. Hunter was duly appointed and given a year's leave to study in Europe, spending most of this period with Prof. Elliot Smith at University College, London.

In his later years in Sydney, Prof. Wilson was keenly nterested in the nerve supply of voluntary muscles and impressed upon his pupils the importance of discoveries made in Holland by Boeke, de Boer and Langelaan—namely, that voluntary muscles have a double supply of motor nerve fibres ; they receive not only the myelinated fibres from the somatic system but also non-myelinated from the sympathetic system. It was the functional significance of this double nerve supply which Prof. Hunter made his own subject. He set himself to master the wide and intricate literature of his chosen subject and found guidance and inspiration in the researches of Sir Charles Sherrington. The theory which he formulated and sought to prove was that all kinds of muscle, both voluntary and involuntary, have a double nerve supply because they have a double function. A muscle must have the power of assuming a new form ; it must also have the power of maintaining the new form thus assumed. Prof. Hunter's theory is that the somatic or myelinated nerves have to do with the first power ; the sympathetic or non-myelinated with the second.

On his return to Sydney, Prof. Hunter found that another pupil of Prof. Wilson—Dr. Norman D. Royle—was also interested in the same problem but from a different point of view. Dr. Royle wished to relieve those soldiers who, as a result of wounds of the brain, suffered from the condition known as spastic paralysis—a condition of muscular spasm which renders easy movement of the limbs an impossibility. Prof. Hunter and Dr. Royle proceeded, after a preliminary series of experiments on animals, to treat these maimed soldiers on the assumption that the spastic condition of the muscles must be due to the action of their sympathetic nerves. Dr. Royle operated and cut off the sympathetic supply, with the result that the spastic condition disappeared and the patients gained an improved control of their limbs.

By the summer of 1923, Dr. Royle had treated some sixty cases with varying degrees of success, while Prof. Hunter had carried out a series of new experiments to elucidate the share taken by sympathetic nerves in regulating muscular action. A sentence from an address which Prof. Hunter gave at this time to an association of Australian medical men illustrates his native modesty and his methods of investigation. "It is the purpose of this address," he said, "to show how this work enables us to correlate for the first time with a sufficient measure of confidence two lines of anatomical and physiological research which have been pursued in various laboratories throughout the world and chiefly have remained as independent observations." Prof. Hunter claimed to play the part of a mere "honest broker" in science. He was doing much more than this. His constructive brain was busily fitting into place the disjointed fragments of an eminently workable hypothesis; and he knew how to devise experiments to elicit evidence.

When these researches were well under way, Australia was visited by the two eminent American surgeons—the Mayo brothers. They were so impressed by what they saw in Prof. Hunter's laboratory and Dr. Royle's wards in Sydney that on their return to the United States they urged the College of Surgeons of New York to invite the Sydney workers to give the Murphy Oration—the highest honour in its gift. The invitation was given and accepted, and in October last Prof. Hunter gave the Oration in New York. This over, he hastened to England to revisit his friends, bringing with him his recently wedded wife. He visited Cambridge and lectured there and then returned to London to lay his discoveries before his old colleagues at University College, when there followed swiftly and unexpectedly the fatal event which has just been told.

Prof. Hunter's investigations were by no means confined to nerves and muscles; he was an anatomist in the widest sense. He was a student of human races, and in co-operation with Prof. Elliot Smith produced a new reconstruction of the Piltdown skull and assisted in the interpretation of the brain of Rhodesian man.

The students of the University of Sydney lose a born teacher and a leader who had gained a place in their hearts. Nor is it too much to say that British science has lost a recruit who carried a marshal's baton in his knapsack. We should convey a totally wrong impression of John Irvine Hunter if we lay stress merely on his power of application, his scholarship, his gift of easily disentangling evidence and of recognising "key" facts, and his mastery of technique. He felt the joyousness of youth and life; he entered into all the pursuits of ordinary men with zest; his interests were wide and he carried himself with a modesty which was natural as it was sincere. In recent years death has robbed science of some of its youngest and most promising votaries but in few cases is there entwined so deep a sense of loss and of tragedy as clings round the death of young Prof. John Irvine Hunter.

DR. C. F. NEWCOMBE.

DR. C. F. NEWCOMBE, whose death on October 19 is just reported from British Columbia, went out to that country about thirty-five years ago from the English Lakes. The lovely coast of the north-east Pacific inspired in him a passionate devotion. With scarcely any scientific companionship, he followed with wonderful singleness of heart the pursuit of knowledge through the rest of his life. He was the moving spirit in the Natural History Society of Victoria, which did much, in the short period of its activity, to reveal, by dredging, the almost incredible riches of the Strait of Juan de Fuca. He himself worked out extensive collections of mollusca and crustacea from this and many other localities.

At the same time Newcombe acquired an exact knowledge of the flora of the coast and made valuable palæontological collections from many parts, but he will always be remembered for his wide and intimate acquaintance with the Indian tribes, especially the Haidas of the Queen Charlotte Islands, whom he regarded with a deep but discerning affection. He made countless journeys from Victoria northwards, often in an undecked motor-boat, and taking great risks. On the last of these he took the chill which caused his death.

Quite early in his work Newcombe marked out a policy from which he never deviated. The decay of the culture and handicrafts of the gifted peoples of the coast could not, he felt, be arrested. The best that could be done for the benefit of posterity was to see that these should be adequately represented in museums by such memorials as their totem-poles, their boats and their carvings. The museums of the United States were not slow to profit by his disinterested efforts. Very many totem-poles, obtained by him only after settling difficult and complicated claims, and snatched, in some cases, from destruction at the hands of their owners, are now the most impressive objects in great anthropological collections. For his trouble he never claimed more than out-of-pocket expenses. Latterly he succeeded in kindling a local interest in these riches, and the museum at Victoria contains many important accessions obtained by him, as does the National Collection at Ottawa. It was a genuine source of regret to him that the Canadian and British Governments and scientific authorities were not sufficiently alive to the importance of these native relics, for he would have vastly preferred to enrich the museums of his own country.

Newcombe never published any accounts of his experiences and observations amongst the coast Indians. No one who had ever talked to him for long could doubt how valuable such accounts would have been. His diffidence and high critical sense dissuaded him, however, from premature publication, and in 1911 the early failure of his eyesight made prolonged writing impossible.

In 1913 Newcombe was placed in charge of a commission to report on the sea-lions of British Columbia and their relations to the fisheries of the Dominion, the report of which embodies his experience through many seasons. It shows his characteristic respect for careful observation and his disinclination to arrive at conclusions except on the strongest evidence, and is a valuable account of the natural history of the animal and its place in native life. Nor can we close this notice without mentioning his intense interest in and laborious research into the records of the discovery of British Columbia. In 1914 the Provincial Government published as a memoir his account of "The First Circumnavigation of Vancouver Island."

To those who enjoyed Newcombe's friendship it cannot but be regretted that such a many-sided, humorous and charming personality has been lost to us without leaving an adequate memorial, and to those who are interested scientifically in the Pacific coast of Canada, the closing of so rich a storehouse of knowledge of a dying race is an unparalleled disaster.

Dr. John Beard.

We regret to record the death of Dr. John Beard, who was lecturer in embryology and in comparative anatomy of vertebrates in the University of Edinburgh from 1890 until 1920. Beard was born in 1858 and received his early scientific training in the Owens College, Manchester, and in the Royal College of Science, London, where he studied under Huxley. He also spent periods of study in the Universities of Würzburg and Freiburg, and became thoroughly conversant with the German literature of zoology—especially in embryology—as well as with that of British and other workers. On his return to Great Britain he was for a time in the service of the Scottish Fishery Board as naturalist at the Marine Laboratory at Dunbar, and it was from this post that he was invited to succeed the late George Brook as lecturer in embryology in the University of Edinburgh. He was soon afterwards appointed also lecturer in comparative anatomy of vertebrates, and he was for some twenty years or more senior assistant to the professor of natural history, Prof. J. C. Ewart.

Beard was most at home in his course of embryology, and in his best years, before his health began to fail, he was a stimulating teacher, one who aroused the true spirit of investigation in his pupils, and of his published work the most enduring is likely to be that which deals with certain features—the nervous system, the thymus, the germ-cells—in the development of elasmobranch fishes. About seventeen years ago he reached the conclusion, largely on embryological grounds, that tumours, benign and malignant, should be treated by means of pancreatic ferments, and the remaining years of his working life were chiefly devoted to the discussion of this question. It eclipsed his interest in his earlier lines of work, but his co-workers in zoology always continued to hope, until his breakdown, that his profound knowledge of the details of development of elasmobranchs, and especially of the skate (Raja), would be made available by publication to future workers.

Beard had a keen mind and was a forceful writer. He had great skill in zoological technique and he formed a large collection of microscopical preparations—chiefly complete series of sections—for the study of the development of Raja. In his later years at the University he was not in good health, and a breakdown in 1920 brought about his retirement from the staff. During recent months his health had distinctly improved, but on November 22 he had a stroke and died in Edinburgh on December 2.

Mr. J. A. Wheldon.

An active and accomplished botanist passed away on November 28, at Aintree, Liverpool, in the person of Mr. J. A. Wheldon. James Alfred Wheldon was born at Northallerton in 1862, and was educated at Cleveland College, Darlington, and the Westminster College of Pharmacy. He qualified as a pharmacist about 1884 and started in business at York, but four years later a disastrous fire robbed him of all his collections. In 1891 he was appointed pharmacist at H.M. Prison, at Walton, Liverpool, a post which he held for thirty years. Until he received this appointment, Mr. Wheldon's botanical studies were chiefly concerned with phanerogams, but from this point he devoted much of his time to mosses. He was one of the founders of the Moss Exchange Club, which afterwards became the British Bryological Society, and during its latest season distributed nearly 5000 specimens, for which Mr. Wheldon acted as referee. In 1907 he published his most extensive botanical work, the excellent "Flora of West Lancashire," in conjunction with Mr. Albert Wilson, but his pen was constantly busy, especially on mosses. In 1901 Mr. Wheldon was elected a fellow of the Linnean Society of London, and withdrew in 1918 upon his retirement; but last year he was elected an associate of the Society, a distinction he greatly valued. He received the honorary degree of M.Sc. from the University of Liverpool in 1922. His botanic collections were extensive and embraced practically every group of cryptogams; they would be a worthy accession to some institution.

B. D. J.

Prof. Franz Schrader.

The death of M. Franz Schrader, formerly of the Ecole d'Anthropologie of Paris, which occurred in October, removes one of the most eminent of French geographers. Born at Bordeaux in 1844, Schrader travelled widely in Europe in his youth and served in the Franco-German war. By the influence of Elisée Reclus he turned to geography, his interests lying in the human rather than the physical aspect. But it is for his cartographical work that Schrader was best known. He completed and published in 1893 the "Atlas Universal de Géographie" begun by Vivien and Saint-Martin many years earlier. The last edition of this atlas was published in 1922 and is the principal French atlas of the time. Other notable works of Schrader were "Atlas de Géographie moderne" (1890) and "Atlas de Géographie historique" (1896). He was the editor of the annual publication entitled "L'Année cartographique," which records all new publications in cartography and exploration. As a keen alpinist, Schrader found much interest in devising his tacheograph by the use of which he produced his "Carte des Pyrénées centrales."

We regret to announce the following deaths:

Dr. J. F. W. Tatham, formerly Superintendent of Statistics at the General Register Office, on November 8, aged eighty.

Dr. T. L. Watson, Corcoran professor of geology at the University of Virginia and director of the Geological Survey of Virginia, who was known for his contributions to mineralogy, petrology, and economic geology, on November 10, aged fifty-three.

Current Topics and Events.

IT is a pleasure to record that Sir James Mackenzie, honorary physician to the King in Scotland, has been awarded the Charles Mickle Prize offered by the University of Toronto for the best work to advance sound knowledge of a practical kind in medical art or science during the last ten years. Sir James Mackenzie is a typical Scot, possessing in a remarkable degree the qualities which have made Scotland famous the world over. These qualities, native ability, imagination, conscientiousness, and dogged perseverance, have raised him from the rank of an ordinary general practitioner of medicine to a high position as an investigator and pioneer in connexion particularly with diseases of the heart. Although there was a very considerable mass of knowledge on the heart long before his time, Sir James had the merit to approach the subject in his own original and thinking fashion, and by following up the histories of his patients in a personal and kindly way he amassed a great amount of knowledge of the fate of patients with cardiac disease, and was able to write on the subject with first-hand knowledge.

LONG a practitioner in Burnley, it was here that Sir James Mackenzie wrote his remarkable work on the pulse and appreciated more than any one of his time that the only real test for a heart is its capacity to deal with the daily work which it has to do. In the course of his work he investigated the irregularities of the heart, classified them on a sound physiological basis, and studied their prognostic significance and their rational treatment. This, we think, is the work by which he will best be remembered. Associating himself with physiologists like Hill, Keith, Flack, Cushny, MacWilliam, and Lewis, he was also largely instrumental in applying physiological work to the needs of practical medicine, and he founded the new branch of cardiology. The later work in which he tried to elucidate the early symptoms of disease by ordinary methods of clinical observation does not appear to have been so successful. Not the least of his merits has been the encouragement which he gave to a band of young workers who have done admirable work in filling up the lacunæ in the cardiological fabric.

ALTHOUGH the valuable material obtained by officers of the Indian Archæological Department on the sites at Mohenjo Daro and Harrappa in the Indus Valley referred to in NATURE of October 18, p. 584, and October 25, p. 623, will need to be supplemented by further investigation, it now appears to be generally agreed that these discoveries have nearly doubled the period covered by our knowledge of Indian antiquities, taking it back to at least 2500 B.C. It is also clear that the finds belong to a widespread culture which must have flourished for many centuries. The peoples of Sind and the Punjab were then already living in well-built cities and were in possession of a mature civilisation. According to a report from Sir John Marshall, quoted in the *Times* of December 10, a careful examination and comparison of the antiquities found leaves no doubt that they are closely connected with, and approximately contemporary with, Sumerian antiquities from Southern Mesopotamia which date from the third or even the fourth millennium B.C. The origin of the Sumerians is obscure, but it is held by many that they were entirely distinct, both linguistically and otherwise, from other races in Mesopotamia, and were an intrusive element from the outside, possibly originating to the east in India. Sir John Marshall, therefore, regards it as a reasonable hypothesis that India was the cradle of the Sumerian civilisation which lay at the root of the Babylonian, Assyrian, and Western Asiatic cultures generally. It is highly desirable that the exploration of Indian sites on an extended scale should be pushed on with as little delay as possible, especially with the view of the elucidation of the pictographic script, which appears to be so closely related to the Sumerian system.

DURING the transcontinental excursion of the British Association and the International Mathematical Congress, after the meetings in Toronto in August last, Sir Richard Paget designed an amusing totem pole representing the various sections of the Association. A reproduction of this drawing, in colour, has been prepared, and will be obtainable from the secretary of the British Association, Burlington House, London, W.1, price 2*s.* (postage 1½*d.*). By Sir Richard Paget's permission the drawing is here reproduced, in black-and-white, reduced by one-third linear dimensions. At the top of the pole is the head of the British Ass. with balancing scales in its teeth. Below it are symbols of the thirteen sections in descending order, namely, astronomy, mathematics, and physics; chemistry; geology; zoology; geography; economics; engineering; anthropology (man looks in a mirror); physiology (a heart and microscopes); psychology (studying a dream); botany (trees and flowers); education (reading a book); and agriculture. There are probably many members of the

FIG. 1.

Association, as well as others, who will like to possess this humorous and apt memento of a notable meeting, in addition to those who ordered it during the excursion.

AT a meeting of the Royal Society of Edinburgh held on June 7, 1920, H.R.H. the Prince of Wales was elected an honorary fellow in accordance with the terms of Law VIII., which provides that "Personages of the Blood Royal may be elected Honorary Fellows at any time on the nomination of the Council." A special meeting of the Society was summoned on December 3 last, at which His Royal Highness was admitted to the honorary fellowship. As in the case of the sister and older Society, the Royal Society of London, the patronage of the reigning King was solicited as soon as it came into being, and a Charter of Incorporation was granted in March 1783. Since then the head of the Royal House, down to and including H.M. King George, has always been an honorary fellow of the Society. The first president was Henry, third Duke of Buccleugh, who communicated in 1785, to Volume I. of the Transactions, an abstract of the register of the weather for ten years kept at Branxholm, near Hawick, a residential seat of his family. The Duke wrote, in this first issue, a dedication to the King and Founder, George III., prefacing the papers published. "If they," he says, "shall be found worthy of the approbation of a Monarch who has distinguished his reign by the utility of his institution for improving the elegant Arts, as well as by the splendour and success of his undertakings to extend the knowledge of Nature, the Royal Society of Edinburgh may hope to occupy a respectable place among those bodies of learned men who, by their united efforts, have contributed so eminently to the progress of Science and of Taste in Europe." The Society now numbers on its roll some 650 fellows.

SERIOUS psychical research has been handicapped so often by the pretences of charlatans that the integrity of an investigator has to pass vigilant scrutiny before his testimony is accepted. It is therefore peculiarly interesting when men like Prof. Gilbert Murray and Lord Balfour give evidence of their first-hand experiences in telepathy. At a meeting of the Society for Psychical Research on December 12, Mrs. Henry Sidgwick described some instances of telepathy shown by Prof. Murray, and she stressed the fact that far from Prof. Murray desiring to prove a preconceived theory, he discovered his telepathic gifts when he was still a sceptic, and, even now, regards his demonstrations more as "parlour-tricks" than as serious investigations. The demonstrations were conducted in the following manner: some one, acting as "principal agent," thinks of the matter—a real or fictitious scene or quotation—which he wishes to convey to Prof. Murray, and describes it aloud to the other people in the room. Prof. Murray is then fetched from another room or some distance in which he has been waiting, and, lightly touching the principal agent's hand, attempts to reproduce the description. His percentage of successes (59 per cent.) and wealth of detail seems to preclude the possibility of coincidence. Mrs. Sidgwick also gave evidence against the view that hyperæsthesia is an explanation of telepathy, showing that no auditory hyperæsthesia could have enabled Prof. Murray to describe incidents, previously unknown to him, which were thought of, but not spoken of, by the agent. Sir Oliver Lodge and Lord Balfour supported the view that telepathy is more than strong sensory activity, and the latter described some successful instances in which he himself had acted as principal agent. The chairman (Mr. Piddington) described the experiments as "the most remarkable experiences of telepathy that the Society had ever had."

FOG under its worst conditions prevailed over England with unusual persistence for three days from Tuesday night to Friday morning, December 9-12. In London and the suburbs the smoke mixing with the fog greatly aggravated its intensity, and both for density and continuance the fog was the worst experienced for many years past. Thick fog was also reported from the midland, eastern, southern, and western districts of England, and from northern France, Belgium, and Holland. Few winters of late have been specially foggy, although there have been some instances of dense fog. In the winters of 1879–1880 and 1890–1 fog was both frequent and dense. Most winter fogs occur in otherwise fine weather with anticyclonic conditions, which are similarly characteristic of fine, dry, and hot weather in the summer. Registration of atmospheric pollution during the fog shows very distinctly its unhealthy and dangerous character. Fogs have often been discussed by meteorological authorities, but that in no way tends to lessen their occurrence or harmful character. The only known purifier is the springing up of a steady or strong wind, by which it is quickly dispersed.

DR. ARTHUR W. HILL, Director of the Royal Botanic Gardens, Kew, attended a meeting of the Jamaica Standing Committee of the West India Committee on December 10, when the question of deforestation was discussed. Dr. Hill directed attention to the grave effects which deforestation is having on the climate and cultivation of Jamaica, and it was decided to urge the Government of the Colony that effect might be given to the recommendations contained in the report of Mr. E. D. M. Hooper, of the Indian Forestry Department, upon the forests of Jamaica, which was published in 1886, so far as they were applicable to the present situation. It was further decided to urge that the existing laws in respect of the prevention of bush fires might be rigidly enforced.

DR. ALEXANDER RUSSELL has been elected president of the Junior Institution of Engineers for the session 1924–25. His inaugural address will be delivered at the Royal Society of Arts on Wednesday, January 7, at 7.30.

THE Right Hon. James Ramsay MacDonald and Sir David Prain, formerly Director of the Royal Botanic

Gardens, Kew, have been elected trustees of the British Museum in succession to the late Sir Archibald Geikie and the Right Hon. E. S. Montague.

THE annual meeting of the Mathematical Association will be held at the London Day Training College on Monday and Tuesday, January 5 and 6, when the following communications will be presented: on Monday evening, "The Mathematical Laboratory: its Scope and Function," Prof. H. Levy; on Tuesday morning, "The Neglect of Arithmetic in Schools," Prof. J. E. A. Steggall; "An Application of the Bessel Functions to a Problem in Optical Resolution," A. Buxton; and a discussion on "Tangency and Limits in Geometry"; on Tuesday afternoon, "What is Geometry?" Prof. G. H. Hardy (Presidential Address), and "The Reform of University Mathematics," Dr. H. B. Heywood.

THE annual exhibition of the Physical Society of London and the Optical Society is to be held on Wednesday and Thursday, January 7 and 8, at the Imperial College of Science and Technology, Imperial Institute Road, South Kensington, from 3 to 6 P.M. and from 7 to 10 P.M. Mr. F. Twyman will lecture on "Some Experiments with Interferometers" at 4 P.M. on January 7 and at 8 P.M. on January 8, and Mr. C. F. Elwell on "Talking Motion Pictures" at 8 P.M. on January 7 and at 4 P.M. on January 8. These lectures will include demonstrations. More than fifty firms are exhibiting scientific apparatus, and a number of experimental demonstrations have been arranged. Invitations have been given to the Institutions of Electrical and Mechanical Engineers, the Chemical Society, the Radio Society of Great Britain, the Röntgen Society, and the Faraday Society. Admission in all cases will be by ticket only, and members of the above societies should apply to the secretary of the Society to which they belong. Others interested should apply direct to Prof. A. O. Rankine, hon. secretary of the Physical Society, Imperial College of Science and Technology, South Kensington, S.W.7.

MR. CHARLES W. J. TENNANT, writing from the office of the district manager of the "Christian Science Committees on Publication for Great Britain and Ireland," says that the references to "Christian" science in letters in NATURE of December 6 are misleading. We are afraid we cannot enter into a discussion of the basis and meaning of Mrs. Eddy's work or the use of the term "Christian scientist" to denote a disciple of it, but it is of interest to give the following extract from Mr. Tennant's letter: "Christian Science is a perfectly legitimate term; it is the Science or knowledge of Christ, Truth; it is exact Science, and can be demonstrated as certainly as mathematics. One of the many definitions of the word 'science' in the Oxford Dictionary is 'organized body of the knowledge that has been accumulated on a subject.'"

THE Imperial Forestry Institute at Oxford started work on October 13, temporary accommodation having been provided in the School of Forestry building until arrangements can be completed for the erection of new buildings on another site. The board of governors of the Institute is now fully constituted as follows: Lord Clinton, Forestry Commissioner (chairman); the Vice-Chancellor of Oxford University, Mr. J. Wells; the President of Magdalen, Sir Herbert Warren; Prof. W. G. S. Adams; Mr. R. L. Robinson, Forestry Commissioner; Major R. D. Furse, Colonial Office; Col. G. L. Courthope, Empire Forestry Association; Prof. R. S. Troup. The following staff has already been appointed: Director, Prof. R. S. Troup; Secretary, Mr. P. S. Spokes; lecturers—economics of forestry, Mr. W. E. Hiley; silviculture, Mr. H. G. Champion; mycology, Mr. W. R. Day; structure and properties of wood, Mr. L. Chalk. The Institute will, in addition, have the assistance of the following members of the staff of the School of Forestry: forest management, Mr. R. Bourne; surveying and engineering, Mr. N. F. MacKenzie. The Forestry Commissioners have agreed to station at the Institute certain of their research officers.

THE Division of Medical Education of the Rockefeller Foundation has decided to collect and publish from time to time brief descriptions of clinics, laboratories, and methods of teaching in different parts of the world in order that the information in convenient form may be brought to the attention of those interested, and the first of these reports has been recently issued (Methods and Problems of Medical Education, First Series, 1924). It includes descriptions, with plans and illustrations, of seven anatomical institutes, including that at University College, London, of two departments of obstetrics (Harvard and Peking), and of the pathological institute at Graz. In each case a sketch is given of the courses of instruction and method of teaching.

PROF. HORST OERTEL, of McGill University, contributes to the *Scientific Monthly* (Nov. 1924, p. 512) an interesting and learned article on the relation of philosophy to medicine. He points out that pathology, for example, the science of disease, has not yet learned to distinguish fully between what is scientifically established and what is assumed. When we speak of bacteria as *causes* of disease, we are, strictly speaking, not correct, and all sorts of indefinite, largely hypothetical conceptions have been introduced, such as virulence, attenuation, variability, resistance, strains, individual susceptibility. All these cover up deficient knowledge of causal relations, and are, at the best, heuristic. Prof. Oertel pleads for a return to Immanuel Kant, to whom we owe so much as a pathfinder of correct scientific thought and reasoning.

THE Department of Health, Canada, has issued a striking pamphlet (Publication No. 32) on "Smallpox and Vaccination," by Dr. J. J. Heagerty. The symptoms and history of smallpox are briefly described, a few statistics of its incidence and mortality are given, and the nature of vaccination detailed. But the salient feature, apart from scarlet covers, is the number of excellent reproductions of photographs,

some showing the disease at its worst, others mild cases and after-effects. But the two most striking illustrations depict, one a smallpox mother nursing with impunity her vaccinated baby, the other three children of the same family, the middle one of the group unvaccinated and covered with the smallpox eruption, while on either side is a child vaccinated a year previously, neither of whom took smallpox though living in the smallpox ward for several weeks.

THE Bulletin of the Imperial Institute, Vol. 22 No. 3, 1924, contains a very full account of the cultivation and propagation of the banana, its transport to the British market, and also its possible utilisation as "flour" or dried slices, "figs." An account is also given of the more usual fungus and insect pests which the banana cultivator has so far had to struggle against. Provided rainfall or irrigation can supply sufficient water in a tropical climate, the banana can be grown successfully on many soils if labour is available; and as at present the greater part of the imports to the United Kingdom come from foreign countries, it is suggested that tropical areas within the Empire might take a greater share in the production of this crop, particularly perhaps West African regions within a comparatively short distance of the home markets. Two species of banana are grown on the commercial scale, a variety of *Musa sapientum* known as "Gros Michel," the principal banana grown in Central America and Jamaica, and *Musa Cavendishii* or *M. sinensis*, a native of Southern China, which was introduced into the Canary Islands, a smaller form than "Gros Michel," of less robust habit, and therefore requiring protection in crates when exported; this is now usually known as the Canary Islands banana.

THE library of the Chemical Society will be closed for the Christmas holidays at 1 P.M. on Tuesday, December 23, and will reopen at 10 A.M. on Monday, December 29.

READERS on the look-out for book bargains should obtain a copy of Catalogue No. 244, just issued by Messrs. W. Heffer and Sons, Ltd., Cambridge, which gives particulars of nearly four hundred "remainders" now offered at greatly reduced prices. Many works of scientific interest are included.

MESSRS. W. Watson and Sons, Ltd., 313 High Holborn, London, W.C.1, have recently sent us a copy of a new edition of their Catalogue of Microscopic Objects. The list is divided into sections, each of which is limited to preparations referring to a particular subject, and in each section related specimens are conveniently grouped under sub-headings. There are also several special educational sets of representative slides. The list covers botany, geology, histology, pathology and zoology, and accessories for microscope technique.

Our Astronomical Column.

THE JOHANNESBURG REFRACTOR.—Dr. Innes was able to give the welcome news at the R.A.S. on December 12 that the object glass of the 26½-inch refractor at the Union Observatory, Johannesburg (made by Messrs. Sir Howard Grubb and Sons, Ltd.), was at last on its way to Africa. It was ordered fifteen years ago, but the War brought work to a standstill. The flint lens is not quite perfect, being slightly veined, but the effect on its optical performance is fortunately trifling.

Dr. Innes spoke of the difficulty of finding sufficient workers to man the large telescopes in the southern hemisphere. After describing the arrangements made for interchange of observers with Leyden Observatory (Mr. Van den Bos is going to observe double stars), he implied that there was still room for further volunteers if the telescope was to be worked to its full capacity.

The fact of there being more than 300 fine nights each year makes a number of observers desirable.

COMBINED OBSERVATIONS OF THE MOON.—At Prof. E. Brown's request, an international plan of intensive observation of the moon during the three months December, January, February is being undertaken, in order to fix the errors of the new tables as accurately as possible. The total eclipse of the sun which occurs in January in the United States will fill in the gap which usually occurs at new moon; it enables the moon's latitude to be fixed with great accuracy. Amateur observers can help by observing occultations, accurate time being now easily obtainable by wireless signals.

Dr. H. Spencer Jones, H.M. Astronomer at the Cape, has just communicated to the R.A.S. a valuable discussion of the occultations observed at the Cape during the last 40 years. They give a value of the solar parallax practically identical with that deduced from observations of Eros in 1900–1, namely 8·806″. He also found a value of the semidiameter of the moon 15′ 32·70″, which is only 0·05″ in excess of that deduced by Struve from numerous observations during lunar eclipses.

THE BAADE PLANET.—The orbit of this body is now accurately known, the following elements having been deduced by Dr. Stracke, of the Berlin Rechen-institut, from observations extending over 32 days.

Perihelion passage, 1924, Sept. 28·38252 G.M.T.

$$\left.\begin{array}{lll} \omega & 130^\circ\ 35'\ 43{\cdot}8'' \\ \Omega & 216^\circ\ 26'\ 19{\cdot}0'' \\ i & 26^\circ\ 9'\ 4{\cdot}0'' \end{array}\right\} 1924{\cdot}0$$

$$\phi \quad 32^\circ\ 37'\ 35{\cdot}5''$$

Period, 4·35326 years.

Least distance from sun, 1·22867: greatest, 4·10353.

Three periods are very close to 13 years, and it is just 13 years since Albert was discovered, the orbit of which resembles it in everything except inclination; but that is only 11° instead of 26°. Also the new body is 4 magnitudes brighter than Albert, implying a diameter of some 20 miles instead of 3 miles, so identity seems impossible (though it was suggested by Dr. Stracke), but there may be some connexion between the bodies. It should be possible to photograph the new body even in aphelion oppositions. It will then be of about the 16th mag.

The least distance from Jupiter's orbit is about 2 units, being increased by the large inclination. The perturbations are considerable, but not excessive, and could not explain the change of inclination from 11° to 26°.

An interesting point is that the orbit approaches that of Mars within 3½ million miles, which is near enough to produce sensible perturbations.

Research Items.

THE PEARL IN OCEANIA.—The prominence given to pearls by Prof. Elliot Smith and Mr. W. J. Perry in their theories relating to the diffusion of culture, has led Dr. A. C. Haddon to make a careful examination of the evidence. The result is published in *Man* for December. Prof. Elliot Smith founded his argument upon the word *Margam*, which he stated meant in Ancient Persian "pearl" and "giver of life"; whereas it means "coral," and the interpretation "giver of life" is based upon an impossible etymology. Mr. Perry accounted for the activity of the colonisers of Oceania in certain areas by attributing it to the love of the islanders for pearl and pearl shell. An examination of the earliest writers on the Pacific shows that of all the natives of the Pacific, the Society Islanders alone had any enjoyment of pearls. When pearls are mentioned elsewhere they appear to have been obtained for the purpose of barter with the Spaniards. In Otaheite, early travellers bear witness that the women wore an ear ornament consisting of three pearls strung together. There is no evidence, however, that pearls had any special significance beyond that. Nor is there in Polynesia any general word for pearl in current use as would have been expected on Mr. Perry's view. The pearl-shell was the essential object, and the pearls were named from it. If the pearl were the prime object of interest to the "archaic" colonisers, it is difficult to see why the original name should have been lost and a derivative name substituted. In Malaysia the terms for pearl and shell suggest that the use was introduced by the Hindus. Pearl shell was both worn and used by Papuans and Melanesians when first we hear of them. There seems to be only one reference to its magico-religious significance. This is recorded by the Rev. Dr. C. E. Fox.

BEISAN FROM THE AIR.—Mr. Clarence S. Fisher has published in the *Museum Journal* (Philadelphia) for June last three photographs, taken from the air, of the excavations of the expedition of the University of Pennsylvania to Beisan. These photographs are part of a series taken by the XIVth Squadron of the Royal Air Force with the permission of the General Officer Commanding in Palestine, which forms a valuable addition to the permanent records of the expedition. The first of the photographs reproduced shows the citadel of Beisan from the east and gives an idea of the magnitude and symmetrical shape of the hill which cannot be obtained from the ordinary photograph. The second view shows the extent of the excavations up to the present, while the third gives a survey of the whole country between Mount Gilboa and the River Jalud which runs at the foot of the main hill of the site. This last is a striking example of the value of the aeroplane in archæological work as it shows how this isolated fortress dominated the area once famous for its fertility, but now mostly occupied by swamps, in a way that would not be possible either in a verbal description or in a photograph taken on ground level.

BIRD-MARKING IN AMERICA.—We have received a paper by Mr. F. C. Lincoln on "Returns from Banded Birds, 1920 to 1923," forming Department Bulletin No. 1268 of the U.S. Department of Agriculture. It consists mainly of tables giving particulars of 1746 records of marked birds recovered in a period of three and a half years, from which figures it is apparent that this method of studying migration has been greatly developed in the United States since the War and is now being exploited on a larger scale. It is of interest to note that this is largely due to its having been taken up officially by the Bureau of Biological Survey of the Department of Agriculture, an organisation which has for long paid much attention to bird-migration, as is witnessed by the well-known work of another of its officers, the late Wells Cooke. One may judge, accordingly, that the importance of seasonal movements in the study of economic ornithology is fully realised. (A parallel is to be found in Hungary alone among European countries.) The new method has evidently been applied with efficiency and thoroughness, and the form adopted for preliminary publication is a useful one. Future papers may be expected to give some analysis of the results and conclusions drawn therefrom, but here this is not attempted. There is, however, a map showing the recovery localities of a large number of mallard marked in Illinois in the spring, autumn and early winter; these are spread over a vast region from the mouth of the Mississippi to Saskatchewan. The results are interesting for purposes of comparison with those already obtained for the same species in Europe, and notably in the British area.

THE MARINE FISHES OF PANAMA.—In an important and exhaustive paper (Field Museum of Natural History, Zoological Series, vol. xv.) S. E. Meek and S. F. Hildebrand give an account of the marine fishes collected during the biological survey of the Panama Canal Zone. They make the review of the fishes of this district complete by including all previously recorded species. The collections were made on both sides of the Isthmus, and the authors find that the Pacific fauna, on the whole, is the richer. They agree that the ichthyological evidence is overwhelmingly in favour of the existence of a former open communication between the Atlantic and the Pacific, sufficiently remote, however, to have permitted the specific differentiation of forms on the two coasts. Seventy-two species are common to the two coasts, but of these, forty-eight are cosmopolitan in their distribution. Two new genera and twenty-three new species are instituted in the first part of this report.

FUNGI FROM NORTH GREENLAND COAST.—As No. 12 of Part II. of the report of the 1916–18 Danish expedition to the North Coast of Greenland, J. Lind has recently described the fungi collected there by the late Dr. Th. Wulff. A point of some interest is the fact that only one parasite, *Melampsora arctica*, is present in the collection, whilst many saprophytes are included, mainly very small Pyrenomycetes and Discomycetes, nearly all of which are invisible to the naked eye, so that the 46 species described would seem a great tribute to the energy and discrimination of the collector. Lind points out that the prevalence of saprophytic forms in North Greenland is undoubtedly due to the fact that the dead parts of plants do not rot away as in more southerly latitudes, "but remain during one or several years forming a protective coating around the young buds and shoots." These old, withered leaves and stalks constitute an excellent substratum for small saprophytes.

CYTOLOGY OF COTTON.—Mr. Humphrey John Denham has published the results of extensive studies of the cytology of cotton in two papers in the *Annals of Botany* (vol. 38, pp. 407-438, 1924), paying special attention to microspore development. The haploid chromosome number proves to be 26, two chromosomes being distinctly larger than the remainder. The author has counted the chromosomes in some 32

varieties of cotton and arrives at the interesting result that the cottons of the New World and Egypt uniformly possess 26 chromosomes, whilst those of Asia have 13 chromosomes. This result probably throws some light upon the difficulty of successful crossing between Indian and American or Egyptian cottons and is therefore of considerable interest to those engaged in the scientific development of cotton-growing within the British Empire. This is probably the reason why Mr. Denham's two papers are also printed in the Journal of the Textile Institute (vol. 15, No. 10, October 1924), but they will prove difficult to readers unaccustomed to technical botanical terminology in spite of the fact that they are preceded by a brief introductory note to which a glossary of technical terms is appended.

TERTIARY AND CRETACEOUS FOSSILS FROM THE ARGENTINE.—Our knowledge of Argentine fossils is not so extensive but that additions, however small, are welcome. Two small papers by M. Doello-Jurado are before us. The one (*Anal. Soc. Cient. Argentina*, tom. xciv.) describes under the name of *Mytilus pseudochorus*, n. sp., the cast of a mytiloid shell from the Santa Cruz formation that has lain some time in the National Museum of Natural History at Buenos Aires, and of which the likeness to *M. chorus*, Mol., had already been recognised by Von Ihering. The other communication (*Physis*, tom. v.) deals with a new species of Viviparus, *V. wichmanni*, from freshwater beds in the Upper Cretaceous of Rio Negro. The author's figures are not very clearly printed, and the doubt may be permitted whether most palæontologists would refer the specimen to Viviparus *sensu stricto*.

WELL-WATERS OF SOUTH AUSTRALIA.—Mr. R. L. Jack publishes three maps and a series of analyses on the well-waters of the South Australian part of the great artesian basin of Australia in the Trans. and Proc. of the Royal Society of South Australia, xlvii., 1923. He strikes another blow at the old view that their waters were all derived by annual percolation from the Queensland hills, by showing that some of it has come from the now arid regions of the very centre of Australia north-west of Lake Eyre. He shows that these waters are of two chemical types, one rich in sulphate and the other in carbonate. The table of analyses records only the chlorine, CO_3 and SO_4. Mr. Jack accepts the view that there should be rigid control to prevent waste of water from the bores, as they are draining water of cisternage which ultimately will only be recoverable by expensive deep pumping. It is unfortunate for the Australian artesian basin that the wholesale waste of the water was so long permitted.

THE WATER-POWER OF SWEDEN.—The growing interest in water-power, especially in countries with little or no coal of their own, adds to the importance of a paper by Mr. S. Norlindh entitled "Översikt över Sveriges Vattenkraft" (*Meddelanden från Statens Meteorologisk-Hydrografiska Anstalt*, Bd. I. No. 5). The publication is mainly statistical and gives very full data of all the important falls on more than 100 Swedish rivers and their main tributaries. For each is given the drainage area, weight and the theoretical horse-power. Other tables give the largest falls and the large falls at present utilised. From comparative statistics of various countries, Sweden with nearly 18 million H.P. appears to be better supplied with water-power than any other country in Europe, next coming Norway and France, each with about 12 million H.P. It is doubtful, however, if world statistics of this nature are altogether comparable since most are merely estimates founded in many cases on inadequate data. A notable part of the publication is a well-produced map of Sweden (scale 1 : 1,000,000) showing the location and horse-power of the chief falls with distinctive colouring for those which are now in use. This map shows strikingly how much power has been harnessed in the south of Sweden and the vast unemployed resources in the north of the country, notable exceptions being the falls on the Luleälv at Porjus and Harspränget in Swedish Lapland.

THE EARTH'S CRUST.—"The Composition of the Earth's Crust," by F. W. Clarke and H. S. Washington (Professional Paper 127, United States Geol. Survey, Washington, 1924), sets out in detail the results obtained by these authors in their most recent examination of the best analyses of igneous rocks available up to the present time. A summary of these results was published in the Proceedings of the National Academy of Science (1922, vol. 8, p. 108), and referred to in NATURE of August 19, 1922, p. 253, where an analysis of the average igneous rock of the earth's crust, and the estimated percentages of the commoner elements in the lithosphere, hydrosphere, and atmosphere, according to Clarke and Washington, were given. The figure obtained is the average of 5159 analyses of specimens of igneous rocks, and should correctly be described as such, rather than as the average igneous rock of the earth's crust. This may be best realised from a consideration of the fact that, of the 5159 analyses, 1985 represent Europe, 1709 North America, and 1465 the rest of the earth. The Pacific is represented by 72 analyses of rocks from Polynesia. On p. 19 of their paper the authors quote the Italian proverb: "Chi va piano va sano." They themselves, however, fail to exemplify the teaching of this good old proverb, for they proceed at an unsafely quick pace when they infer that an average of the available analyses of specimens of igneous rocks shows the average composition of the earth's crust.

UPPER AIR OBSERVATIONS.—Successful results of observations in the upper air by means of *ballon sonde* and pilot balloon are given in the *Meteorological Magazine* for October and November. A Dines meteorograph, according to the number for October, was sent up from H.M.S. *Kellett* in the English Channel on June 16. Two balloons were employed in tandem. The apparatus fell into the sea near Eastbourne and was returned to the Meteorological Office. The lifter balloon was followed by means of glasses and is thought to have burst at a height of about 12 km. (7 miles). At sea-level the atmospheric pressure was 1014 mb. and the temperature 68° F.; at 3 km. (1·8 miles) pressure was 709 mb. and temperature 43° F.; at 5·4 km. (3·3 miles) pressure was 520 mb. and temperature 12° F. Two *ballon sonde* ascents were made from the meteorological station at Sealand Aerodrome, near Chester, on July 14 and 15, each of which reached a height of about 20½ km. (12·3 miles); this is the greatest height reached in Great Britain for 12 years. The November number gives a note on a high pilot balloon ascent at Shoeburyness on May 28. The balloon was followed with two theodolites up to a height of 50,000 ft. (9·5 miles), when the home station lost it. The ascent reached well into the stratosphere. To a height of 16,000 ft. the wind was south-easterly with a speed of 10 m. per hour; it veered to south at 25,000 ft., and beyond this height it continued to veer becoming south-west, 20 m.p.h. at 30,000 ft.; beyond 40,000 ft. it backed slowly and decreased. At 50,000 ft. the wind was west or west by south and very light. At the time of the ascent there was a depression far out in the Atlantic and an anticyclone extended eastward from the southern Baltic; the pilot balloon thus showed the southerly circulation between the two.

PERIODICITY OF TEMPERATURES IN EUROPE.—A. Wagner, in a paper read at the Academy of Sciences, Vienna, in July of this year, presented evidence for the existence of a 16-year periodicity of temperature in Europe, based on the examination of long series of data for Vienna and other stations. He finds that the phases of this cycle are opposite in summer and winter, so that it is best seen in the annual range. The amplitude is greatest in Central Europe, whence it decreases southwards and especially northwards, but the phase remains constant. Along a line from Stykkisholm through Stockholm to Petrograd the periodicity vanishes, to reappear farther north with the phases exactly reversed. The author is quite satisfied as to the reality of the periodicity, but until the full evidence is available it would be premature to express an opinion. It should, however, be pointed out that if the periodicity is as definite as the author claims, its length is not sufficiently defined. A cycle of 16 years may imply anything between 15·5 and 16·5 years. If it is real, the series of 147 years' observations available at Vienna should be quite sufficient to determine the length to one place of decimals. If every discoverer of a periodicity would set himself to calculate accurately its length and amplitude before giving it to the world, there would be less confusion in the subject.

THE ELECTRICAL CONDUCTIVITY OF ROCK-SALT CRYSTALS.—A very comprehensive investigation of the electrical behaviour of rock-salt, at temperatures ranging from 15° to 500° C., is described by Dr. D. v. Seelen in the *Zeitschrift für Physik*, October 23. It was found that all the specimens available required a preliminary treatment by heating to 400° ; measurements made before this treatment did not agree with those made under similar conditions afterwards, but the effect of the heating was to give a material which had a fairly definite conductivity and temperature coefficient for each temperature. One of the experiments, in which three polished plates were carefully weighed, piled between silver plates, heated to 400° C. for several days while a current was passed through them and again weighed, showed that conduction took place according to Faraday's law, and was electrolytic in character. Sodium ions (Na^+) are the only carriers of electricity, and chlorine ions (Cl^-) do not travel through the crystal. The distribution of potential along the length of the crystal was investigated ; it does not follow the straight line law, and space charges in the interior of the crystal have to be assumed. There is nothing which alters the potential distribution, such as double layers or space charges, at the electrodes. The author considers that his experiments indicate a loosening of the crystal lattice as a preliminary to conduction ; under the conditions of his experiments the formation of metal bridges in the crystal lattice was not possible, and the fact that the crystals did not lose weight when heated all day to 400° excluded the possibility that conduction was due to salt solution included in the crystal.

RANGES OF POLONIUM α-RAYS IN OXYGEN AND NITROGEN.—Mlle. I. Curie, using air in the Wilson apparatus, formerly obtained a very different result for the above distribution than that given by the scintillation method, and found that the latter does not detect the majority of the rays towards the end of their range. In the *C.R. Acad. Sci. Paris*, Oct. 20, Mlle. Curie and Mr. N. Yamada describe measurements in oxygen and nitrogen. The number of particles with ranges between x and $x+dx$ is proportional to $\epsilon^{-\xi^2/\alpha^2}$; $\xi=x-\rho$, ρ being the most probable range, and α an experimental constant. The value of α/ρ for nitrogen is 0·0208, for oxygen 0·0208, and that previously found for air is 0·015. The exact equality of the values of α/ρ for oxygen and nitrogen is partly fortuitous, the difference in the case of air being due to the greater thickness and possible irregularity of the preparation and impurities. It appears that the difference in the form of Bragg's ionisation curves for oxygen and nitrogen is due to the law of variation of ionisation along the α-ray, and not to any difference between the distribution of ranges in the two gases.

HALIDES OF SILVER.—The photochemical decomposition of silver bromide has recently been investigated by E. J. Hartung with the aid of the microbalance (Jour. Chem. Soc., November). It is interesting to note that experiments on the rate of bromination of thin films of metallic silver afforded no evidence of the formation of silver sub-bromides or perbromides. Thin films of silver bromide, when sealed up in a vacuum in the presence of copper gauze and placed in the light, lose more than 96 per cent. of their bromine. These results support the non-existence of silver sub-halides, and they bear out the conclusions reached by Reinders in 1911 and Bancroft in 1923.

ELECTRO-ENDOSMOSIS.—A contribution to the study of electro-endosmosis, by F. Fairbrother and H. Mastin, appears in the Jour. Chem. Soc. for November. The calculation of the potential gradient along the walls of the capillaries in the diaphragm of an electro-endosmose apparatus involves uncertain assumptions, and a method is described for overcoming these difficulties. In effect, the method consists in measuring the "cell-constant" of the diaphragm, the conductivity of the calibrating liquid being assumed. Measurements with carborundum powder in acid and alkali are recorded ; the electrokinetic potential, calculated from the modified Helmholtz equation, reaches a maximum in dilute alkali ; it decreases as the concentration of the latter decreases and as the concentration of the acid increases. At the intermediate point (water) the carborundum is negatively charged ; the value −0·0698 volt is found for the potential between the two parts of the double layer in distilled water. No reversal of the direction of electro-endosmosis was found with carborundum in hydrochloric acid solutions up to N/50 strength.

THE ATOMIC WEIGHT OF ANTIMONY.—In the November number of the Journal of the American Chemical Society, P. F. Weatherill describes experiments on the atomic weight of antimony. Antimony trichloride, prepared from pure antimony and chlorine in a vacuum, was repeatedly distilled in a vacuum in an all-glass apparatus. It was dissolved in a solution of pure tartaric acid, and compared with pure silver. The mean of nine analyses gave Sb = 121·748 ± 0·00086, which may be compared with the value 121·77 obtained by Willard and McAlpine from the analysis of the tribromide, and the value 121·76 obtained by Hönigschmidt from the analysis of both the tribromide and the trichloride. By taking all three independent researches into account, a value of 121·76 would seem to be close to the truth. The value 120·2, which has appeared in the tables for a number of years, is much too low. It may be remarked incidentally that no atomic weight table appears to have been published by the International Commission since 1921, and that a new table would seem to be due. Differences of the order indicated affect ordinary analytical practice.

Crystal Structure.

DURING the Toronto meeting of the British Association, Sir William Bragg's presidential address was followed by a discussion on crystal structure.

Prof. W. L. Bragg described the manner in which the refractive indices of certain crystals, the structure of which has been determined by X-ray methods, can be quantitatively explained. In calcite, for example, the arrangement of atoms in the planes perpendicular to the trigonal axis consists alternately of calcium ions and CO_3 groups arranged at the corners of a triangular network. The three oxygen atoms are closely packed round a central carbon atom and lie parallel to the planes. Wasastjerna has given reasons, based on the similarity of the refractivities of the molecules or ions Al_2O_3; SO_3; NO_3 and CO_3, for assuming that the refractivity in such groups is to be ascribed to the *oxygen* atoms.

If, then, the carbon atom in the CO_3 group is left out of account, it appears that an electric field perpendicular to the trigonal axes, and so parallel to the plane of the CO_3 group, causes a polarisation of the oxygen atoms which is greater than it would be for an isolated atom. On the other hand, an electric vector perpendicular to the CO_3 plane produces a less polarisation than it would do for a single atom. This polarisation is equivalent to the creation of a set of electric doublets the moments of which will be greater in the first case than in the second. It is evident that the velocity of a wave in the crystal, depending on the ratio of the total polarisation per unit volume and the intensity of the electric field, will be less when the electric vector is perpendicular to the trigonal axes than when it is parallel to these axes. The crystal has a high refractive index for light with its electric vector parallel to the CO_3 planes or perpendicular to the trigonal axis, but a low refractivity for light having its electric vector perpendicular to these CO_3 planes.

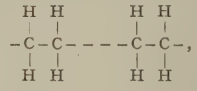
It is possible to calculate the polarisation of the atoms of calcite under a given field. Since the relative positions of the atoms are known, it is possible, by making the assumption that the polarised atom has an external field identical with an electric doublet placed at its centre, to calculate the two refractive indices.

Values of the refractive indices calculated for calcite and aragonite, both crystalline forms of calcium carbonate, show very good agreement with observed values.

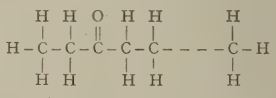
Prof. S. Chapman explained how he and Prof. W. L. Bragg had attempted theoretically to calculate the rhombohedral angles of crystals of the calcite type. A number of carbonates form rhombohedral crystals similar to calcite, having an angle between the crystallographic axes of about 102° for the whole series. The calcite type of crystal has the form of a cube shortened along a diagonal (its trigonal axis) and consists of ions of the form R^{++} and CO_3^{--}. The CO_3 planes, as described above, are perpendicular to this axis. It is, therefore, possible to picture a distortion of this crystal along a trigonal axis such that the type of the lattice is preserved, and the distance between neighbouring oxygen-metal or carbon-oxygen centres is constant. It is found that the electrostatic potential energy per gram molecule of calcite, when calculated for a series of such positions, has a minimum value for an axial angle of about 106°. The difference of 4° can be accounted for as being due to the simplicity of the assumptions underlying the calculation. The *variation* of the angle in a group of crystal-carbonates containing different metallic ions can be accurately accounted for by the different sizes of the metallic ions.

When considering the arrangement inside a crystal, it is obvious that the atoms must be held in position by forces symmetrically disposed. This symmetry disappears at the surface, so the surface layers must possess properties different from those of the mass. Prof. C. H. Desch described experiments made with gold, showing that the cohesion and surface tension of a crystal do not necessarily decrease at the same rate with rise of temperature. The surface tension at high temperatures is sufficient to round the sharp angles of a crystal, so that beads of gold slowly cooled have a skin resembling a film of gelatin over them. This can be removed by etching to expose the normal structure.

In discussing the structure of the long chain carbon compounds, Dr. Shearer emphasised the fact that the measurements he and Dr. Müller had made pointed to the existence of a simple relation between the dimensions of a single molecule and the dimensions of the crystal cell. When X-ray spectrograms of compounds are measured which have a structure based on the chain

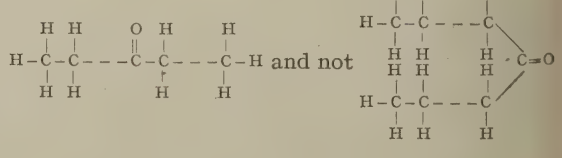


it is found that the most prominent lines are due to one spacing which is much larger than the others. For substances which differ only in the number of CH_2 molecules in the chain there is a regular progressive increase in the size of this spacing as the number of CH_2 groups increases. Frequently, if the number of carbon atoms in such a chain is plotted against the spacing, the points lie on a straight line, and approximately the spacing is either equal to or twice the length of the molecule. The double spacing is characteristic of molecules having an active group at one end; hydrocarbons, esters, and ketones, which have no active group at the end, show the single molecule spacing. For example, measurements of a ketone series such as



gave a single molecule group. It is interesting to note, however, that five methyl ketones, in which the oxygen is attached to the penultimate carbon atom, gave the double spacing. When the spacing of these methyl ketones is divided by two, these compounds take their place on the straight line representing the other ketones. Evidently in the methyl ketones the oxygen is sufficiently near the end of the chain to behave as an active group. This result indicates the effective range of attraction of the oxygen atom.

There are three rates of growth indicated for chain compounds, appearing to show that the CH_2 molecule can occupy three different lengths in the chain. Suggestions have been made to account for this variation in length by different arrangements of the carbon atoms in the chain. These measurements appear to give a real meaning to stereochemical formulæ. It appears, for example, that ketones have the structure



The spectra of double molecule chains give, as one would expect, strong odd orders and weak even, whilst the single chains give orders decreasing uniformly in intensity.

Mr. S. H. Piper gave some examples of the use of X-ray spectra in distinguishing between long chain compounds of similar types. It was possible to show that the fractions obtained by distilling paraffin wax *in vacuo* were not identical with normal hydrocarbons. For example, one fraction having the same number of carbon atoms in the chain as dotriacontane showed a very much smaller spacing. All fractions appeared to photograph as pure substances, and it was interesting to notice that the lines shown by a film of crude paraffin wax melted on glass gave the same spacing as one of the eight fractions. On mixing this fraction with one or more of the others, its lines only appeared on the plate.

Dr. Müller mentioned that the main spacing given by certain hydrocarbons appeared to have two possible values, indicating two possible crystalline structures for these substances.

Mr. W. T. Astbury indicated how it is possible to determine from X-ray measurements, by making use of the theory of space groups, the elements of symmetry possible to the molecules in the crystal cell. It is then possible to distinguish between two or more structural formulæ for a given compound. A most valuable series of tables was shown giving the possible molecular symmetry for all the 230 space groups.

Oyster Mortality in 1920.

PART I. of the report under notice [1] was reviewed in NATURE of July 19, p. 82. It contained Dr. Orton's Final Report, while Part II. commences with his Interim Report of December 30, 1920, which apparently is now published for the first time. It shows the preliminary biological investigations that were made by Dr. Orton, together with his examination of the dumping-ground for explosives in the Black Deep, and is altogether admirable. Why this was not printed in proper sequence, these being the preliminary conclusions of the same author, it is impossible to understand. Further, if it had been published as soon as received instead of in 1924, it would have relieved the minds of those concerned with the oyster industry, and probably elicited from them much further information, besides stimulating and directing their own observations; those responsible for the industry are not unheeding of the results of scientific research.

Dr. Orton's interim report is followed by a series of valuable research reports on special questions. Dr. Eyre's very thorough investigations, mainly shown in tables, lead to the conclusion that no evidence points to the excessive mortality being due to *disease* of bacterial origin. Dr. Brady tested very thoroughly from the chemical side and came to a similar negative conclusion in respect to the dumped munitions of war. The Government Chemist and his staff in four reports are largely concerned with arsenic, which is very widely contained in silts formed from rocks containing arsenic. As diseased and healthy oysters have the same amount, this clearly cannot account for the mortality, nor is there any suggestion of the mortality possibly being due to "dumping" of arsenic compounds either by factories or by the Munitions Department. However, the possibility of arsenic in oysters being of danger to man is unavoidably raised, especially as the silts of the Fal contain large quantities of copper, zinc and tin also, whereas these are practically absent from the oyster grounds of the Thames estuary and the East coast. The present reports, critically examined in connexion with former researches, give no cause for any suggestion of danger to human life from these substances as consumed by the most gluttonous lover of oysters. Yet, we do not think these researches should stop here without a more definite examination and pronouncement on this question by the Government Chemist, whose staff must now have considerable experience in the necessary analyses, and who can consult as may be advisable with the expert physiologists of the Ministry of Health.

If the analyses of any oysters give any suggestions of danger, the beds from which those oysters come must clearly be closed for direct sales, the fish being first laid elsewhere for a period sufficient to remove the noxious substance, as is required for bacterial infections. What is first required, however, is a definite pronouncement as to what constitutes danger. Without this the present report will inevitably give rise to alarm, if it ever becomes known to the "man in the street." This is unlikely, however, as it costs 7*s.* 6*d.* for 69 pages, without illustrations, and free copies are not distributed. This is scarcely the way in which to make scientific research popular. Our Government authorities have much to learn from a study of the effect of a liberal free distribution of similar reports in the United States. J. S. G.

Part 2: Chemical Reports, (1) by George Stubbs, Andrew More and John Ralph Nicholls, and (2) by Dr. O. L. Brady; Bacteriological Reports, by Prof. J. Eyre; Report on Field Work, by F. S. Wright; Biological Investigations, by Dr. J. H. Orton; Recommendations as to Further Research, by Dr. J. H. Orton. Pp. 69. (London: H.M. Stationery Office, 1924.) 7*s.* 6*d.* net.

The Thermal Efficiency of Steam Engines.

A DISCUSSION on the standards of comparison in connexion with the thermal efficiency of steam engines was held at the Institution of Civil Engineers on Thursday, December 11. The Heat Engine and Boiler Trials Tabulation Committee has appreciated the fact that the present standard of comparison needed development, and asked Capt. H. Riall Sankey to prepare a memorandum on the subject with a view to discussion at a joint meeting of the Institutions represented on the Committee (*v.* NATURE, December 6, p. 835). The 1896 Committee of the Institution of Civil Engineers, under the chairmanship of Sir Alexander Kennedy, proposed the Rankine cycle as a standard. Since that time the practice of heating the feed-water by live steam abstracted from the engine during expansion, known as "bleeding," has been developed, resulting in considerable economy, but to this case the Rankine cycle does not apply. The practice is also adopted of reheating the steam after a partial expansion, a process which can be repeated once or more, after which the steam is expanded to the back pressure, but it would be stretching the definition of the Rankine cycle to apply it to this case. Further, these feed-heating and reheating cycles can be combined, and the question arises, can a standard of comparison be defined that will meet all cases?

It is submitted that the following extended definition can be applied to all cases :

It is assumed that all the component parts of the steam plant are perfect, and that there are no losses due to initial condensation, leakage, radiation, or conduction, and that there is no clearance in the cylinder. The feed-water required is taken into the boiler at the exhaust temperature, and its temperature is gradually raised until that corresponding to saturated steam is reached. Steam is then formed at constant pressure until dry saturated steam is produced, after which, if the steam is to be superheated, heat is added at constant pressure and at increasing temperature, until the required temperature of superheat is reached. The steam is introduced into the cylinder at constant pressure, displacing the piston, and performing external work equal to the absolute pressure multiplied by the volume swept through by the piston up to the point of cut-off. Beyond that point expansion takes place adiabatically, doing work until any desired pressure is reached, when the steam is reheated at constant pressure to any desired temperature whence adiabatic expansion takes place ; such reheating process can be repeated as often as desired. Finally, the steam is expanded adiabatically until the temperature of saturation corresponding to the boiler pressure is met. From this point, *either* adiabatic expansion continues doing work until the pressure in the cylinder is equal to the back pressure against which the engine is working, *or* the steam is expanded so that a portion of the heat is transferred to the feed-water in such a manner that at every temperature the amount of heat so transferred is equal to the increase in water-heat at that temperature, until the pressure in the cylinder is equal to the back pressure against which the engine is working. The steam is then completely exhausted from the cylinder at constant pressure corresponding with the lower limit of temperature, work being done on the steam by the engine during exhaust, equal to the absolute back pressure multiplied by the total volume swept through by the piston. The steam is thus removed from the cylinder and the cycle is complete.

In practice, the following main cases occur resulting from the omission of one or more of the factors of the comprehensive definition :

(1) Saturated steam with simple adiabatic expansion to the back pressure.

(2) Superheated steam with simple adiabatic expansion to the back pressure.

(3) Superheated steam with one or more reheats with final adiabatic expansion to the back pressure.

(4) Saturated or superheated steam with feed-heating expansion to the back pressure.

(5) Superheated steam with one or more reheats, and final feed-heating expansion to the back pressure.

The thermal efficiency of any heat engine is defined as the ratio of the heat utilised as work to the heat supplied. Capt. Sankey gives some worked-out examples to illustrate the method, and makes use of the Mollier chart and of Callendar's Fahrenheit Steam Tables. He also includes tables of results of a large number of other calculations for different cases, and includes among these one illustrating the Benson cycle, in which steam is generated at the critical temperature (706° F.) at a pressure of 3200 lb. per sq. inch absolute. For comparison, the thermal efficiencies of a gas engine and of an oil engine have also been worked out and are included in the tables.

Capt. Sankey's memorandum gives some idea of the arduous task which the Committee has had to face, and the final recommendations will be welcomed by the engineering profession.

Parker Plant for Low Temperature Carbonisation.

ATTENTION has already been directed in NATURE (September 20, p. 441) to the Government offer to test at public expense approved processes for the carbonisation of coal at low temperatures. The Low Temperature Carbonisation Company, Ltd., has been quick to submit for test the standard unit of "Parker" plant installed near Barnsley at Barugh (locally pronounced "bark," it may be added for the enlightenment of the uninitiated). The Department of Scientific and Industrial Research has now issued a report of the test made in July last. The Director of Fuel Research in a prefatory note emphasises that the report is on technical results only, and that "no attempt is made to pronounce on the commercial possibilities of the plant."

The coal is carbonised in vertical iron tubular retorts, 9 ft. long and of average diameter of 5 in., the retorts being cast in groups of 12 assembled in a setting of 32 groups. The setting is heated by the gas made, and is equipped with closed chambers below the retorts to receive the coke after carbonisation, and allow it to cool without quenching and consequent contamination with moisture. Such a setting was designed to have a throughput of 50 tons of coal per day, and in the test, lasting two days, it was found that this claim was substantiated.

The coal employed was "Dalton Main," with which the Fuel Research Station had already considerable experience. It was a washed slack, fairly dry, containing 5 per cent. only of ash—a low figure for commercial supplies of coal. The yields of products per ton of coal as charged were :

Coke	13·92 cwt.
Gas	5620 cub. ft. or 39·6 therms.
Tar	18·62 gallons.
Crude Spirit (motor)	1·78 gall. yielding 1·39 gall. of refined product.
Liquor	26 gall., equivalent to 13·55 lb. of ammonium sulphate.

The coke produced, the report states, was of suitable size, not friable, contained little breeze, and only 4 per cent. of volatile matter. It successfully withstood an eight-day railway journey to the Fuel Research Station, was readily ignited in a household grate, and gave a good hot fire. It would appear, therefore, that the claim that the process produced a smokeless domestic fuel was substantiated. The analysis showing a volatile content of some 4 per cent. raises a doubt as to whether this fuel will develop the "cheerful blaze" which is so attractive to lovers of a coal fire, and contributes so much to speed of ignition.

The yield of tar was high, and chemically it was of the "low temperature" character. The yield of crude motor spirit was moderate, but the refining loss and consequent cost was considerable. The quantity of ammonia recovered per ton was good for low temperature practice, though low judged by existing carbonising practice, while the liquor obtained was so dilute that it is considered doubtful whether recovery was commercially justifiable.

The whole of the rich gas made was employed in heating the setting, supplemented by some producer gas specially generated. Compared with modern carbonising practice, this is a high fuel consumption, and it is pointed out in the report that a reduction could be effected by better design of the plant. The loss of this rich gas is more serious commercially, as the gas is the most valuable and least speculative

by-product of low temperature carbonisation. It may be assumed that the gas will eventually be put to some better use than heating the setting, for otherwise the financial burden of the process would have to be carried entirely by the coke and the tar and light oil—conditions which do not hold promise of smokeless fuel at a low price. As regards the economics of the process in general, though the report expresses no opinion, the data given as to plant and labour do not suggest low costs when compared with those of current carbonising practice.

The general impression which the report conveys is that the process yields a carbonised fuel regarded as meeting domestic requirements which will probably prove costly per ton, and the scope of the process will depend on whether the general public will be prepared to pay the price for such smokeless fuel in order to avoid the atmospheric pollution following the use of raw coal. H. J. H.

Applied Science at the University of Brussels.

THE highly successful celebrations in connexion with the fiftieth anniversary of the founding of the Applied Science School of the University of Brussels were held in the latter half of November, and were attended by the King of the Belgians, who received the foreign delegates, and also by the Duke of Brabant, who laid the foundation stone of a new building which will continue the development of the University. The city of Brussels and private donors have contributed largely to this scheme, as also the American Committee for the relief of Belgium. Great progress has been made in the buildings for pure and applied science at Solbosch, on the outskirts of Brussels, where, with ample space at disposal, it has been possible to erect a very fine block of buildings in the form of a hollow square.

Physics and chemistry are very well housed and equipped, and especial care has been taken to provide a number of small rooms for research work. The electrical engineering laboratories are remarkably well planned, and especially so as regards the arrangement of their numerous power circuits, which are carried round the walls below the windows and are protected by wire grillages. These circuits are connected to a number of panel units also completely enclosed and provided with the usual resistances, switch gear and measuring instruments all connected up in such a manner that students can readily trace out the various circuits, to which access is gained by numerous doors.

The main laboratory for investigating the strength and other physical properties of materials is chiefly notable for a fine equipment of Amsler testing machines housed in a spacious room provided with an overhead crane, and there are also a considerable number of accessory instruments for measurement and calibration work. A special photo-elastic laboratory is also arranged for in connexion with this department.

The laboratories for technical thermodynamics and hydraulics are now in course of equipment and are on a large scale typical of continental views of such matters, and, like the other laboratories, have well-lighted basements with considerable head room, an arrangement which is especially convenient for steam plants and machinery dealing with the flow of liquids.

In connexion with the celebrations, a number of scientific and technical addresses were given, and numerous other functions were arranged by the Government, the University, and the civic authorities. E. G. C.

University and Educational Intelligence.

ABERDEEN.—The University Court has appointed Dr. A. Bowman to the lectureship on the scientific study of fisheries, in succession to Dr. T. Wemyss Fulton, resigned.

Prof. A. Findlay has proceeded on leave of absence to the United States, where he will act as substitute professor of chemistry at Leland Stanford University for the next nine months.

CAMBRIDGE.—The report of the Botanic Garden Syndicate refers to continued financial anxiety despite the generous support of Mr. Reginald Cory. A prospective legacy from an old friend of the Garden is referred to in the report at her special request in order that it may stimulate others to follow her excellent example. In the recent death of Mr. R. I. Lynch, Curator of the Garden from 1879 until 1919, a link with the past has been snapped. One item of interest in the report is the exchange of shrubs from the Garden for birds from the Zoological Society of London, two pairs of mandarin ducks having been recently received.

The John Bernard Seely Prize, formerly given for an essay in aeronautics, is in future to be awarded to the candidate who does best in aeronautics in the Mechanical Sciences Tripos.

EDINBURGH.—Sir Richard Lodge, who has been Dean of the Faculty of Arts for thirteen years, has resigned this office, and the Faculty has elected Prof. E. T. Whittaker to succeed him as Dean. Prof. Hudson Beare and Prof. Lorrain Smith have been re-elected Deans of the Faculties of Science and Medicine respectively.

At its last meeting the University Court, on the recommendation of the Senatus, appointed Dr. Claude B. Ker, lecturer in infective fevers, to be a senior lecturer, with a seat on the Faculty of Medicine and on the Senatus, and Dr. E. M. Horsburgh, reader in technical mathematics, to be a member of the Senatus.

Dr. Douglas A. Allan, at present an assistant in the Department of Geology, has been appointed lecturer in geology in Armstrong College, University of Durham.

LONDON.—The following doctorates have been awarded:—*Ph.D.* (*Science*), Mr. R. E. W. Maddison (King's College) for a thesis entitled "Part I.: The action of light on chlorine water and aqueous hypochlorous acid solutions; Part II.: Retardation and acceleration of certain chemical reactions by light of different wave-lengths"; Sachindranath Sen (Imperial College—Royal College of Science) for a thesis entitled "On the design of the Kew pattern barometer."

WE learn from the *Chemiker Zeitung* that Prof. A. von Parseval has been nominated to the newly instituted chair of aviation at the Munich Technical Hochschule; and that Dr. Wilhelm Eitel, professor of physico-chemical mineralogy and petrography at Königsberg, has been invited to the chair of mineralogy at Freiburg-im-Breisgau.

APPLICATIONS are invited from medical graduates for the Marks lectureship in applied physiology and the Sheridan fellowship in the University of Adelaide. The applications, with testimonials, statement of academic qualifications, published researches, and a recent photograph, should be sent before the end of January, marked outside "Application for Marks Lectureship," to the Vice-Chancellor of the University, c/o the Agent-General for South Australia, Australia House, Strand, W.C.2.

FOLLOWING closely on the announcement of a gift by Mr. G. Eastman of about 3,000,000*l.* for educational purposes, which was referred to in this column last week, came a message from the New York correspondent of the *Times* announcing a further munificent gift to American education. It is stated that Mr. James B. Duke, who is connected with the tobacco and water-power industries, has created a trust fund of about 8,000,000*l.* for establishing a university in North Carolina which will bear his name. Should Trinity College at Durham in that State agree to change its name to Duke University, the trustees of the fund are authorised to expend 1,200,000*l.* in expanding and extending it, otherwise this sum will be used to start immediately the building of the new university. The trust provides that 20 per cent. of the income from the capital shall be withheld until an additional 8,000,000*l.* has been contributed from other sources. Other educational institutions, churches, hospitals, etc., in North and South Carolina will also benefit under the trust.

A PAMPHLET has been issued by the London County Council containing the lectures for teachers which have been arranged for the coming year. Some of the courses are repetitions of those given during the past term and announced in the handbook of lectures issued last August (see NATURE, August 30, p. 334). New courses include a series on some of the public services of London, each lecture of which is to be delivered by an authority. Among the lecturers are Mr. T. Hardie, of the Gas Light and Coke Co., on the manufacture and distribution of gas; Sir Alexander Houston, of the Metropolitan Water Board, on pure water supply; Mr. J. H. Rider, on electricity supply. Special single lectures will also be given by Mr. W. H. Barker and Prof. P. M. Roxby on problems of tropical Africa and the political geography of the Far East respectively, while Dr. Cyril Burt is to deliver two courses of five lectures each on sub- and super-normal children. Particulars of the lectures can be obtained from the County Hall, Westminster Bridge, London, S.E.1.

AT the annual meeting on November 20 of the Carnegie Corporation of New York, the president and treasurer presented reports, and a brief statement has been printed in *Science*. From this account it appears that the assets of the Corporation on October 1, 1923, were about 26,700,000*l.*; this sum constitutes two trusts for the advancement and diffusion of knowledge and understanding among the people of the United States and in Canada and other British Dominions respectively. During the past year about 2,600,000*l.* was paid out from the former trust and about 18,000*l.* from the latter. Noteworthy grants (approximately in pounds sterling) made during the year were as follows: Carnegie Institute of Pittsburgh, 3,265,000*l.* (the largest single grant made in the history of the Corporation); National Research Council and National Academy of Sciences, 1,000,000*l.*; educational institutions in Eastern Canada, 600,000*l.*; Institute of Economics, 330,000*l.*; Food Research Institute (Stanford University, California), 141,000*l.*; Johns Hopkins Medical School, 400,000*l.*; New York Academy of Medicine, 200,000*l.*; American Library Association, 37,000*l.*; Harvard University (for training personnel for museum service), 20,000*l.*; Institute of International Education, 36,000*l.*; Society for the Promotion of Engineering Education, 22,000*l.*; University of California (for the study of pyorrhea), 17,000*l.*; Union University (Albany Medical College), 10,000*l.*; various agencies for insulin research, 9000*l.*

Early Science at the Royal Society.

December 20, 1677. Mr. Oliver Hill read a written discourse of his, about the method which the Society ought to take in their proceedings, much different from what they then followed.

December 21, 1663. It was ordered that Dr. Merret and Dr. Whistler inquire of some members of the College of Physicians concerning the form of the warrant for bodies to be demanded from the sheriff of London for dissection, and make report thereof.

1664. There were read three several accounts of the comet lately seen, one by Sir Robert Moray, as he observed it December 17 at Whitehall; another sent from Portsmouth, as it was seen by the earl of Sandwich on board of the London at Spithead; a third sent from Ireland, as it was seen at Dublin by Mr. Kearney and another gentleman severally.

1671. Mr. Isaac Newton, professor of mathematics in the university of Cambridge, was proposed candidate by the lord bishop of Salisbury.

December 22, 1686. A paper of Dr. Papin about shooting a spherical bullet by exhausting the air out of the barrel was read, and the experiment shown: but by reason of the night the fall of the bullet could not be seen, and therefore the experiment was ordered to be made some other time [Earl of Carbery, president].—Mr. Hooke read his discourse concerning shells, etc., wherein he gave several material instances to prove, that there have been very great changes in the earth's surface, as of rows of oister shells found in a cliff in the Alps, sea-sand and shells at a great depth in St. James's fields, and the like shells observed by himself at a great hight from the sea, in a cliff in the Isle of Wight.

December 23, 1663. Occasion being given to discourse of tormenting a person with the sympathy-powder, Dr. Wren related, that in the house of a kinsman of his, the experiment had been tried by him upon a servant, who had grievously cut her finger; and a rag rubbed upon the wound being dressed with calcined vitriol, and put into the maid's bosom, her finger within a short time was cured. Whereupon he had taken the rag from her and heated it upon the fire, whilst the maid was sweeping the next chamber; who, upon a sudden, flung away the broom, and cried out for the pain in her finger; which being looked to was found very fiery: upon which they cooled the rag again, and dressed as formerly, and within a day or two the finger was intirely cured. Mr. Boyle undertook to try this experiment upon a dog.

December 24, 1662. Mr. Charles Howard was proposed candidate by Col. Tuke, and was presently chosen; his desire being to be rather admitted by scrutiny, than by the privilege of his birth.—Sir Robert Moray and Mr. Bruce made several relations of accidents which had happened in coal-mines; and were desired to give them in writing.

December 27, 1666. It was ordered, that the operator Richard Shortgrave, do for the future bring no bill of work done for the society without some avoucher, who shall be a curator of the respective experiments, about which he shall have been employed: and that without such avoucher, no account of the said operator shall pass in council: with which order he, being called was made acquainted. [This "operator" would appear to have acted as such for ten years, since at the expiration of that period, we read that it was ordered that "the apothecary's bill for the last sickness of the late Mr. Shortgrave be paid by the treasurer, his widow having first delivered up all the instruments, utensils, etc., belonging to the Society."]

Societies and Academies.

LONDON.

Royal Statistical Society, November 18.—G. Udny **Yule**: The growth of population and the factors which control it. Prof. Verhulst's law implies that the percentage rate of increase falls continuously, and in the simplest case is a linear function of the population at any moment. Verhulst's work fell into oblivion, but recently and independently has been suggested by Profs. Pearl and Reed. If a population unaffected by migration follows such a law of increase, it can only be by the death-rate rising, or the birth-rate falling, or generally by the death-rate rising continuously *relatively* to the birth-rate. The death-rate tends to increase with density of population, but in recent times in civilised States this tendency has been completely outweighed by the progress of medicine, and the death-rate has fallen rapidly in spite of great increases in population. This suggests that, in recent times at least, the birth-rate has been the controlling factor. If a population, subjected to constant death-rates at every age, grows in accordance with a law of the kind suggested, the death-rate tends continuously to increase—at first slowly, then more rapidly, and then slowly again—owing to the increase in the proportion of the old. The facts in general, in particular the very early stage at which the fall in the rate of increase becomes apparent, suggest that the growth of population is a biologically self-regulating process and that the regulation is highly sensitive. Malthus's conclusion that the checks to population may be fairly resolved into misery and vice is an exaggerated statement of the case.

Royal Microscopical Society, November 19.—G. R. **de Beer**: The histology of the pituitary body. The anterior lobe of the pituitary body has been known for some time to contain cells of two markedly different kinds, and the problem has not been solved as to whether these kinds represent distinct cell-types, or different stages of functional activity of one kind of cell. Critical fixation and staining with particular Romanowsky stains reveals the difference in staining-reaction between the two types of cells, and the interesting point that no intermediates appear, at least in the cat and the ox. Examination of the nuclei, the nature of the granular contents of those cells which can be proved to be active in secretion, and of the Golgi apparatus, reveals variability. The argument from comparison, however, and especially with the rabbit, where intermediates appear, and forms lower on the vertebrate scale of evolution, suggest that the latter of the alternative hypotheses is true. Critical methods emphasise the distinctness of the recently recognised pars tuberalis.—Miss J. **Latter**: Pollen development in *Lathyrus odoratus*. The resting nuclei of the pollen mother cells of *Lathyrus odoratus* exhibit a large nucleolus in which a crystalloid, probably of protein nature, is constantly present. The reticulum is of a very granular appearance, becoming definitely thread-like during synapsis. The post-synaptic thread at first lies in large irregular loops throughout the nuclear cavity, one loop always being connected with a deeply staining body in the nucleolus, possibly a modified form of the protein crystalloid. Seven loops of the thread persist, each comprising a pair of homologous chromosomes united end to end, and they radiate from the centre of the cavity. The name *broxonema* is given to this stage. The arms of the loop become intimately twisted round one another, thus affording opportunity for exchange of segments between the homologous chromosomes of a pair. This provides a possible physical basis for the phenomena of crossing over.—W. N. F. **Woodland**: Some remarkable caryophyllæids from siluroid fishes of the Sudan. Caryophyllæus is of special interest as being an example of a monozoan cestode. Until last year, less than a dozen species were known, all very similar to each other. The new caryophyllæids differ greatly from all those previously discovered and form a new genus Wenyonia. Wenyonia differs from Caryophyllæus in having the sexual apertures situated in the anterior half of the body, in the longitudinal extent of the uterus being as great or greater than that of the testes, in the vitellaria being medullary instead of cortical, and in some other respects.

Linnean Society, November 20.—H. A. **Baylis**: Cestodes from whales of the genus Balænoptera. The first form referred to was the recently described *Priapocephalus grandis* Nybelin, a tetrabothriid in which the typical suckers and auricular appendages of the scolex have disappeared, and the scolex has been modified into a bulbous "holdfast," which is buried in the lining of the host's intestine. Great similarity exists between the scolex of Tetrabothrius and that of Dinobothrium, a genus usually referred to a different group of cestodes, the Tetraphyllidea. It was suggested that, through such forms as these two genera, the Cyclophyllidea and Tetraphyllidea grade into each other.—J. R. **Norman**: Blind cave-fishes. The known forms now number about seventeen, to which may be added an undescribed blind catfish recently received by the British Museum (Nat. Hist.) from the Guacharo Caves, Trinidad. The cyprinodont family Amblyopsidæ contains eight species variously distributed in the United States, seven of which live permanently in subterranean waters, while one inhabits open streams. All have more or less degenerate eyes, which are merely vestigial in five species. In most of them sensory papillæ have been developed on the head and body to compensate for the loss of vision. The two blind fishes occurring in caves in Cuba belong to a marine family, the Brotulidæ. In both the eyes are vestigial and covered with skin in the adult, but small and well developed in the young. The head is provided with small tactile appendages. The remainder of the blind cave-fishes are all members of the order Ostariophysi, and occur in America and Africa. Two of them, belonging to the cyprinoid suborder, are related to the widely distributed genus Barbus; the remainder are allied to various members of the sub-order Siluroidea (catfishes). The eyes present varying degrees of degeneration, sometimes even in the same species, and accessory sensory organs are sometimes developed. The association of degenerate eyes with cavernicolous habits thus appears in several very different families and in many widely separated regions of the world.—G. H. **Stilwell** and H. **White**: *Pyrus lagenarius*. The tree was raised from seed gathered by E. H. Wilson for the Arnold Arboretum, in 1910, at Tachien-lu, in the Province of Sze-chuan near the Tibet frontier, at a height of between 5000 and 6000 feet. The original bush is now 9 feet high. The flowers are red and white. The leaves large, persisting on the ends of the shoots during the winter, and after a few years it fruits freely. The fruits become a beautiful golden-yellow by Christmas, and make a delicious jelly. It appears quite hardy in the South of England, and grows rapidly.

Physical Society, November 28.—Discussion, arranged jointly with the Royal Meteorological Society; Ionisation in the atmosphere, and its influence on the propagation of wireless signals.—W. H. **Eccles**:

A brief history of wireless telegraphy in relation to atmospherics, and an outline of the parts that may be assigned to diffraction, the Heaviside layer and ionic refraction is given. Certain facts, such as the errors of direction finding at night, and the success of long-distance transmission using short wave-lengths, offer confirmation of the hypothesis of an ionised layer in the upper atmosphere.—C. **Chree**: Atmospheric ionisation and its variations. For instantaneous values it suffices to know the potential gradient and either the conductivity or the vertical air-earth current; but in the case of mean values a knowledge of all three elements is necessary. Information as to diurnal variation is very scanty, except in the case of potential gradient. The monthly values in the annual variation, and the hourly values in the daily variation, are expressed as percentages of their arithmetic means. This is done partly because less uncertainty attaches to relative than to absolute values in the case of all the electrical elements. Reference is made to some conclusions as to the diurnal variation of potential gradient and the existence of a sun-spot period recently arrived at by Dr. Bauer and Dr. Mauchly, of the Carnegie Institution of Washington.—E. V. **Appleton**: Geophysical influences on the transmission of wireless waves. The variability of signals may sometimes be attributed to the varying phase and amplitude of rays ionically refracted by the upper atmosphere. The diurnal variation of such signals is described, and the strong night signals attributed to a lower atmosphere devoid of excessive ionisation. The facts of wireless telegraphy show that the atmosphere exerts a variable but usually favourable influence on wave propagation. This influence may be interpreted in terms of ionic refraction (Eccles), which, to prevent excessive dissipation, must take place at levels sufficiently high to make the mean free paths of the effective carriers large (Larmor).—R. A. Watson **Watt**: Atmospherics. The results of an examination of the meteorological conditions prevailing at apparent sources of atmospherics, as located by direction finding, show that, even with the limited data available, relations with thunderstorm phenomena, precipitation, or barometric minima have been traced in 87 per cent. of 490 cases, distributed over Europe, the Mediterranean, and North Africa. The tracing of a "cold front" for forty hours over 2000 km. across Western Europe, by directional recording of atmospherics, is reported. —C. T. R. **Wilson**: The electric field of a thunderstorm and some of its effects. A thundercloud may be pictured as having its upper and lower regions oppositely charged, the positive charge being most commonly on the lower side. The cloud lies at a moderate distance above the earth, while the Heaviside layer lies at possibly 100 km. above the earth. A lightning flash constitutes a short-circuit, in the absence of which the charges may leak away to the earth and the Heaviside layer respectively. Three possible causes of ionisation are suggested: (1) The charges on the cloud may ionise by induction at heights where the density of the air is very small. An ordinary cloud may have a sufficient electric moment to produce a similar effect, since this moment may be great even where the charges themselves are small, provided that the charges are separated by a great depth. (2) Beneath a thundercloud there is an intense potential gradient, producing a heavy earth-air current; the intensity of this current is hidden near the earth by the fact that part of it passes upwards through trees and the like. (3) The radio-active matter in the atmosphere produces β-particles, the energy of which, under the influence of the immense potential differences available, may be so great as to impart to the particles a kinetic mass equal to the mass of hydrogen atoms.—S. **Chapman**: The evidence of terrestrial magnetism for the existence of highly ionised regions in the upper atmosphere. Balfour Stewart's "atmospheric dynamo" theory of the daily magnetic variations is described; the earth's permanent magnetic field is the magnetic field of the dynamo; the atmosphere (undergoing small, but extensive, motions owing to thermal or tidal causes) is the moving armature; and particular ionised regions in the upper strata correspond to the "windings" in which the induced currents flow. The variations of ionisation are the chief cause of the changes of intensity in the diurnal magnetic variations, as between day and night, winter and summer, and sunspot minimum and sunspot maximum. Hence these changes in the magnetic variations indicate the changes in the ionisation of the atmospheric regions concerned. There seem to be two modes of ionisation, both due to the sun, and affecting different regions; one region, ionised by ultra-violet radiation, is a practically world-wide layer, possibly at about 50 kilometres above the surface; this is most intensely ionised directly under the sun in the sun-lit hemisphere, and the ionisation diminishes during the night. The other region consists of the polar caps within the auroral zones, and especially these zones themselves; this region is ionised by the impact of corpuscles emitted from disturbed regions on the sun's surface.

CAMBRIDGE.

Philosophical Society, November 24.—C. T. R. **Wilson**: The acceleration of β-particles in strong electric fields such as those of thunderclouds. An electric force of two-thirds of the sparking value is sufficient to give to a β-particle, travelling in air in the direction of the field with a velocity corresponding to 20,000 volts, additional energy which exceeds by the equivalent of about 10,000 volts the average rate of loss per cm. of air traversed. As the energy of the particle increases under the action of the accelerating field, the chance of survival of the particle increases, and the critical magnitude of the field required to produce a resultant gain of energy diminishes, reaching a limiting value for fast β-particles of about 1000 volts per cm. In the strong electric fields extending over great distances associated with thunderclouds, the energy acquired by β-particles may reach extremely high values, and X- or γ-radiation of correspondingly high frequency may be associated with them. Thunderclouds may thus be sources of "penetrating radiation."—G. F. C. **Searle**: The determination of the frequency of an alternating current supply by the vibration of rods.—F. W. **Aston**: Photographic plates for the detection of mass rays. The sensitivity of photographic plates to mass rays bears practically no relation to their sensitivity to light. The process of improving the qualities of the plates by "schumannising" is discussed and details are given of the procedure so far found most advantageous.—E. B. **Moullin**: On the current induced in a wireless telegraph receiving antenna.—R. R. S. **Cox**: Note on the chemical constant of chlorine.—L. **Bastings**: The decay constant of radium emanation. By comparing the activity of two nearly equal sources of radium emanation, first separately, and later together, with a standard radium source, by the aid of a simple β-ray electroscope, the decay constant of the emanation has been deduced, $\lambda = 0{\cdot}1808$ day^{-1}, or half-period $3{\cdot}833$ days, with an accuracy of at least 1 in 500.—E. L. **Davies** and G. N. **Livens**: The kinetic theory of metallic condition.

EDINBURGH.

Royal Society, November 24.—J. A. **Eldridge**: Note on Prof. Whittaker's atomic model.—J. **Tait** and W. F. **Emmons**: The mechanism of massive movement of the operculum of *Balanus nubilis*. The interest of this movement lies in the fact that, in its defensive reaction against any irritation caused by the lodging of an object on the opercular membrane, *Balanus nubilis* makes forceful rotatory movements of the operculum, the effect of which is to grind or crush the intruding object between the shell and the tergal plates. The pressure so exerted is very great, and yet there is no articulation of the operculum with the shell involving the contact of solid bearing surfaces. The forceful movement of the operculum with the strong lateral pressure which it can exert is due to two factors: (1) the horizontal component in the pull of the obliquely directed fibres of the powerful depressor muscles, and (2) hydrostatic pressure within the fold of the opercular membrane on the opposite side, the internal pressure being found to reach so much as 430 mm. of mercury.—T. J. **Jehu** and R. M. **Craig**: Geology of South Uist and Eriskay. The outstanding feature in the geology of the region is the great belt of crushed and sheared rock extending from north to south for a length of 22 miles along the mountainous eastern side of the island. The base of the belt is marked by an extraordinary development of flinty crush rock. This is succeeded to the east by sheared and crushed gneisses, mylonites, and highly mashed gneisses. The gneisses within the belt and west of it were originally of much the same characters and are all of igneous origin, belonging to the Archæan Complex. Dykes of later age include olivine dolerites, quartz dolerites, and lamprophyres. The ice flowing in from the Minch was to some extent deflected by the mountains on the east. The coastal features afford evidence of recent subsidence.—W. **Saddler**: The irreducible system of concomitants of two double binary (2, 1) forms. The problem of finding this system, which is theoretically known to exist, is here solved by Gordan's method of transvectants. Hitherto the only system for two or more given (m, n) forms which has been enumerated is the bilinear case when $m = n = 1$.—A. C. **Aitken**: A series formula for the roots of algebraic and transcendental equations. A series for symmetric functions of any number of the roots of an equation, of which Whittaker's series is a case.

SYDNEY.

Linnean Society of New South Wales, September 24.—Mr. R. H. Cambage, president, in the chair.—A. J. **Turner**: Revision of Australian Lepidoptera. Lasiocampidæ. The name Lymantriadæ is adopted instead of Liparidæ, on the ground that Liparis was preoccupied by Scopoli in the Pisces and cannot be used in the Lepidoptera. The Eupterotidæ, previously recognised as a separate family, are merged in the Bombycidæ. One new species of Lymantriadæ, one of Anthelidæ, one of Saturniadæ, and one of Notodontidæ are described. The natural position and classification of the Lasiocampidæ are discussed, and all the known Australian species, 54 in number and referred to 12 genera, are completely revised.—R. J. **Tillyard**: Upper Permian Coleoptera and a new order from the Belmont Beds, N.S.W. Six specimens of remains of insects from the Upper Permian of Belmont are Coleopterous elytra—four small ones which appear to be ancestral to the Upper Triassic Ademosyne and allies, one large one which is considered to be an ancestor of the existing Hydrophilidæ, and one which belongs to the order from which the Coleoptera arose, for which a new order is proposed, intermediate between the Carboniferous Protoblattoidea and the true Coleoptera. Two new families are described in the order Coleoptera, with two new genera and six new species.—John **Mitchell**: (1) A preliminary reference to a new species of Elonichthys from the lower beds of the Newcastle Coal Measures. (2) Further reference to the occurrence of *Merista plebeia* Sowerby in New South Wales. (3) Eleven new species of Aviculopecten from Carboniferous rocks, Myall Lakes, N.S.W. These form an interesting addition to those already recorded from the Carboniferous and Permo-Carboniferous rocks of Australia. Their occurrence, unaccompanied by a single species known from rocks of similar age elsewhere, is of interest.

Royal Society of New South Wales, October 1.—Dr. C. Anderson, president, in the chair.—M. B. **Welch**: Note on the structure of some Eucalyptus woods. An anatomical investigation of the structure of Eucalyptus timbers may enable these woods, which often resemble each other closely, to be identified with greater accuracy. Thus there is a much greater development of parenchymatous tissue in what are regarded as the more primitive Eucalypts. The species specially dealt with are *E. maculata*, Hook., *E. pilularis*, Sm., and *E. microcorys*, F. v. M. In the latter, numerous oil globules occur, principally in the medullary rays. The presence or absence of tannin, the form of the rays, and the arrangement of the wood parenchyma are valuable diagnostic characters.—W. A. W. **de Beuzeville** and M. B. **Welch**: A description of a new species of Eucalyptus from southern New South Wales. The new Eucalypt was found at an elevation of 4000 feet on the Main Dividing Range, in the vicinity of the Big Badja Mountain. The bark is characterised by the presence of large groups of oil glands, which measure up to 0·25 mm. in diameter.—A. R. **Penfold**: The essential oils of *Melaleuca erubescens* (Otto) and *M. hypericifolia* (Smith). The former is a heath-like shrub with reddish purple flowers, whilst the latter is a handsome shrub with beautiful crimson bottle-brush flowers, and both occur in New South Wales. They both yielded pale lemon-yellow oils much resembling those of Eucalyptus, and were found to contain cineol, a-pinene, dipentene, limonene, a-terpineol, sesquiterpene, etc. *M. hypericifolia* yields the lowest quantity of oil and lowest percentage of cineol when growing near the coast in exposed positions, and the maximum yield of oil and cineol when obtained from moist rocky situations on the mountain ranges.—W. R. **Brown** and W. S. **Dun**: The stratigraphy of the basal portion of the Permo-Carboniferous system in the Hunter River Valley. The discovery of a fossil identified as *Eurydesma hobartense* in mudstones at the top of the Lochinvar shale indicates definitely that this must be regarded as the basal member of the Lower Marine division of the Permo-Carboniferous strata in the Hunter Valley, as originally suggested by Prof. David.—E. **Cheel**: Notes on Melaleuca, with descriptions of two new species and a new variety. Four of the species somewhat resemble the common Swamp Tea-tree (*Melaleuca ericifolia*) and have been previously confused with it, but certain structural characters, the geographical distribution, and chemical evidence distinguish them. A species somewhat resembling a Mountain Bottle-brush is described as a new species. It is fairly plentiful in the south coast districts of New South Wales. A new variety is also described from the Port Jackson district, having been found to have distinctive characters from the plants originally found in Tasmania. A species from the northern parts of the

State is also raised to specific rank, as it has very different characters from the Toad-flax-leaved Tea-tree with which is has previously been confused.

VIENNA.

Academy of Sciences, October 23.—K. **Stosius** and E. **Philippi**: On the action of ammonia on the esters of citraconic acid, mesaconic acid, and itaconic acid.—A. **Kailan**: On the chemical effects of penetrating radium radiation on potassium bichromate, potassium chromate, and potassium permanganate.—H. **Handel-Mazzetti**: Descriptions of new Chinese plants in the genera Carpinus, Podophyllum, Ehretia, Microcaryum, Trigonotis, Onosma, Ceropegia, Pentasacme.—L. **Abolin**: The influence of chemicals on colour change in fish. The action of infundin and adrenalin on the melano- and xantho-phores of the minnow Phoxinus. The assumption of male erythro-phore colouring by females treated with infundin.—V. F. **Brotherus**: New Chinese mosses from the Handel-Mazzetti expedition.

November 6.—Molecular compounds of phenols. IV.—G. **Weissenberger**, F. **Schuster**, and K. **Schuler**: The behaviour of binary systems with phenol and phenol-ethers. V.—G. **Weissenberger** and F. **Schuster**: Vapour pressure curves.

WASHINGTON.

National Academy of Sciences (Proc. Vol. 10, No. 10, October).—P. W. **Bridgman**: Some properties of single metal crystals. Crystals of zinc, cadmium, bismuth, antimony, tellurium, and tin were examined. Some interesting results are as follows: zinc, linear compressibility is nearly seven times as great parallel to the rotational axis as perpendicular to it, and electrical resistance decreases under pressure. Tellurium, linear compressibility parallel to, and thermal expansion along, the axis are negative. Electrical resistance, except for antimony, is greatest across the plane of easiest cleavage or slip. Cadmium forms two polymorphic forms at 20° C. under pressures of 3000 and 6000 kg./cm.^{2}—A. A. **Noyes** and H. W. **Estill**: Effect of insulin on the lactic fermentation. Insulin increases by 20-25 per cent. the amount of acid produced from glucose by *Lactobacillus bulgaricus*. It is hoped that work on these lines will aid in standardising insulin preparations.—M. T. **Bogert** and M. **Chertcoff**: A new group of dyes from poison gases through the 2-aminothiazoles as intermediates. The preparation of thiazole dyes of Doebner violet type. These substances dye silk, wool, and mordanted cotton a green tint similar to malachite green, but bluer and more dull. They are fugitive in direct sunlight. The poison gases used were dichloro ether, chloroacetone, and chloroacetophenone.—M. T. **Bogert** and P. S. **Nisson**: (1) The synthesis of terephthal green and terephthal brilliant green from cymene. These new dyes, compared with malachite and brilliant green (triphenylmethane derivatives), dye wool and silk a yellower green. They compare favourably in tinctorial power and fastness. (2) Further experiments in the field of the terephthalic acid derivatives.—E. B. **Wilson** and W. J. **Luyten**: A statistical discussion of sets of precise astronomical measurements (IV.); the mass-ratio in binaries. The apparent clustering of mass-ratios about unity is probably due to observational selection; the actual association may not be materially different from random mating.—H. **Shapley**: Note on the thermokinetics of dolichoderine ants. The speed of ants varies with changes of temperature. When the temperature was under control, maximum speed was attained by one species of ant, Tapinoma, at 36° C. Through a limited range of temperature, the speed-temperature ratio is constant.

NO. 2878, VOL. 114]

Twentieth-Century Universities of England.

"ENGLAND, which till lately has had but two universities in the proper sense of the word, will have a dozen, and perhaps the United Kingdom will have a score." So prophesied Sir John Seeley in 1887. By 1909 this forecast had been proved approximately correct: the realisation of projects now pending for raising the University Colleges of Nottingham and Reading to the status of full universities would complete its fulfilment exactly. At present England has ten universities, all of which, except Oxford, Cambridge, and London, were constituted in the first ten years of this century—thirty years after the decade (1871–81) within which were founded nearly all the colleges in which they had their origin.

The first year of the twentieth century saw the granting of a charter to the University of Birmingham (the pioneer in England of the unitary teaching or "single college" type) as the result of zealous and persistent efforts on the part of a group of progressive educational politicians under the leadership of Mr. Joseph Chamberlain. In 1903 the Universities of Manchester and Liverpool, and in 1904, Leeds, received their charters, superseding the charter of 1880 by which the Victoria University was founded as a federal institution. Ten years later, Lord Haldane said of the Order in Council consenting to the charters for Manchester and Liverpool: "The date of this order is, I think, a memorable one. It gave State recognition to a new policy. . . . The principle was accepted that the number of the English Universities was to be increased, and their headquarters were to be in cities." Next came the University of Sheffield, in 1905. In 1908 a charter was granted under which the University of Durham, founded in 1832 under ecclesiastical auspices, was reconstituted as a federal university, with a Newcastle division consisting of the College of Medicine and Armstrong College. The youngest of this family of seven is Bristol, which received its charter in 1909.

This remarkable activity in university-making is attributable in no small measure, as Prof. Newton has lately pointed out,[1] to the discussions which preceded the reconstitution in 1900 of the University of London, consolidating, as they did, public opinion as to what a modern university should be, and stimulating the desire of the provincial university colleges to achieve full autonomy. Dr. A. C. Headlam's interpretation of this opinion may be usefully compared with Seeley's pronouncement a generation before. "A University," wrote Dr. Headlam in "Universities and the Empire," "ought to be an autonomous self-governing corporation, with a constitution of such a character that the influence of broad-minded learning may be supreme.

[1] "The Universities and Educational Systems of the Empire" (Collins, 1924).

Its aim should be *the creation of intellectual life* and the promotion of the highest form of teaching, side by side with original research and investigation." Seeley, in the course of an address delivered in the Town Hall, Birmingham, in 1887, said: "Modern civilisation needs a vast quantity of science: the demand for trustworthy knowledge, scientific, sanitary, technical, economical, political, historical, moral and religious, rises with urgency from these great towns. . . . It is a demand for knowledge, not for training. It is not made in the interest of the young. It calls for institutions by which the whole science of the age may be brought within the reach of all, young and old alike; in short, it calls not for new schools or new colleges in the Oxford and Cambridge sense, but, in the strictest sense of the word, for new universities." Generous as were Seeley's aspirations, the italicised words in the quotation from Dr. Headlam (not italicised in the original) indicate a notable advance since Seeley's day in current conceptions of the functions of a university. We can now say that the discovery of new knowledge and the extension of intellectual fields which follows from it, are an essential part of university life in all departments.

If one looks back to the circumstances of the foundation of the colleges in which the twentieth-century universities originated, one is struck by the fact that they began in most cases as science colleges. Armstrong College, Newcastle-on-Tyne (incorporated in the University of Durham in 1908), was founded in 1871 as the Durham College of Physical Science. Yorkshire College, destined thirty years later to become the University of Leeds, was established as a College of Science in 1874. University College, Bristol, began as a College of Arts in 1876, but the Merchant Venturers' Technical College was associated with it in 1876, and rapidly developed. In 1879 and the following year respectively were founded, as Science Colleges, Firth College, Sheffield, and Mason College, Birmingham. Lastly, in 1881, University College, Nottingham, was opened as a science college, and University College, Liverpool, obtained its charter.

Of the various movements and events which contributed to the establishment of these University Colleges in such rapid succession, and gave them so marked a bias on the side of science and technology, much was said in the course of the jubilee celebrations which took place at the University of Leeds last week. Among them may be mentioned: the Mechanics' Institutes movement, which attempted to stimulate and satisfy the desire of industrial workers for a knowledge of the great discoveries of science, the progress of these discoveries and the rapid development of their applications to industry, the consequent inadequacy of the apprenticeship system of training engineers; the Women's Emancipation movement; the University Extension movement, the Exhibition of 1851 and, perhaps still more, the Paris Exhibition of 1867; the Elementary Education Act of 1870; the Schools Enquiry Commission, and the Royal Commissions on the Universities of Oxford and Cambridge. One of the most powerful of the motives influencing leaders of public opinion at the time was that of providing scientific teaching for students in manufacturing towns, in order to enable England "to maintain her position as the manufacturing centre of the world."

We should be sorry, however, to suggest that the claims of science in education must be presented to an educated community purely on utilitarian grounds. Few scientific workers would now advance that view, and most would agree that in university work the spirit of research should be that of the pursuit of knowledge for its own sake rather than for the profit to be gained from it. The principles upon which the chief modern industries are founded, and the elements used for various purposes in manufacture, were almost all first discovered by investigators working in university and other laboratories without any motive of industrial application before them. It is remarkable to note, for example, that not a single chemical element has ever been discovered in an industrial laboratory, and that the rare elements which are now of such importance in modern developments would never have been thought worth consideration as a means of making profit in a manufacturing works.

Lord Balfour referred very definitely to these aspects of science in a university in an eloquent speech on December 15 at Leeds in connexion with the university celebrations there. "Science itself," he said, "cannot be pursued effectively in the spirit of wealth acquisition. To have applied science you must have pure science, and you will never get pure science to be what it might be, or knowledge really furthered effectively, until those who try to further it are animated in the main, not by material gains, but by the joy of augmenting knowledge itself."

With a right balance maintained between pure and applied science at universities, there must also be something beyond mere technical efficiency in either, namely, regard for the humanistic aspects of all studies. The new humanism of modern science should not permit itself to be strangled by the cordage of over-specialisation as has been the old humanism of classical learning; and if scientific studies are to exert their full influence upon our generation, students of them must be more than experts in their particular subjects—they must be human and social as well. Where this spirit is combined with rich knowledge and the desire to increase it, university training represents intellectual life at its highest and best.

"Elephants in American Art."

Elephants and Ethnologists. By G. Elliot Smith. Pp. viii + 135 + 52 plates. (London: Kegan Paul and Co., Ltd.; New York: E. P. Dutton and Co., 1924.) 15*s.* net.

IN the book which is before us Prof. Elliot Smith has reverted to a subject upon which he enlarged in NATURE some years ago (1915–16). By bringing together under one cover the full evidence upon which he relies in his argument, he has endeavoured once for all to dispose of what he calls the "stereotyped form of criticism," and finally to defeat those who do not endorse his views as to the Asiatic origin of certain items in the culture of Central America. He has succeeded in producing a readable and interesting treatise which is focussed upon a special feature in the art of Copan, and he offers this confidently as a test case in support of his major and more generalised theory. His argument is developed with skill, and he uses all his power as an advocate. But his handling of a much-debated and still debatable problem is, unfortunately, marred by frequent reliance upon dogmatic assertion. The Bellman's axiom, "What I say three times is true," may serve to limit discussion during a Snark-hunting expedition, but is unlikely to be accepted as finally convincing in scientific debate, and serves rather to stimulate than to allay criticism. Prof. Elliot Smith's doctrine would have gained strength, and possibly adherents, had he urged it less aggressively and devoted himself to the elimination of inconsistencies and to the more careful analysis of the evidence upon which he relies. His constant assertion that the case is proved, seems to suggest that further argument is needless. In spite of that, after reading carefully his in many ways able "discussion on one sharply defined issue," one still feels that scientific proof of the main hypothesis is yet to be found and that the problem remains unsolved.

The main discussion centres upon certain zoomorphic designs carved in relief upon the famous "Stela B" at Copan in Honduras, designs which Prof. Elliot Smith asserts represent the heads of Indian elephants, and cannot reasonably be mistaken for anything else (Fig. 1). Others have urged that these conventionalised animal themes have been derived from earlier attempts to represent *indigenous* faunal types, *e.g.* the macaw, the tapir, etc.; while, quite recently, Dr. H. O. Forbes has forcibly urged that the animal fancifully rendered is a cephalopod of some sort, possibly modified through fusion of this *motif* with the macaw theme.

FIG. 1.—Zoomorphic designs sculptured on "Stela B," Copan, Honduras. (After Maudslay.) From "Elephants and Ethnologists."

To Prof. Elliot Smith the design in question represents an "unmistakable Indian elephant ridden by an equally characteristic turbaned *mahout*" (p. 5). This being stated as a fact should end the discussion; but several points of importance call for further inquiry. Prof. Elliot Smith himself allows that the artist, in his attempt to portray an "elephant," was "unacquainted with the features of a living elephant" and "has mistaken its eye for the nostril and its ear for the

eye"; and he endeavours to explain away certain other features which are inconsistent with realistic rendering; and further (p. 112) he refers to "the remarkable modifications effected in the form of the creature when the conventionalised picture is transferred to regions where the animal itself is unknown." And yet, on p. 89, in referring to the Copan "elephants," he indulges in the description "so exact a representation of an animal . . ."—a palpable overstatement.

The author lays considerable stress upon certain details of the "elephant" design. He says, for example, "The external ear (pinna) is also accurate as to size and shape" (p. 7); but this fidelity to actual shape is by no means clear, and the form of this feature actually varies in the four representations of it (Fig. 1, A, B, C, and D), rendering the term "accurate" a somewhat elastic euphemism. He also refers (p. 7) to the position of the tusk as helping to reveal the animal's "identity as an Indian elephant." But where is the "tusk" in the Copan sculptures? Are we to recognise it in the upper one of the pair of patches of cross-hatched lines which occur on each side of the "trunk"? The markedly reversed curve of its outline seems to militate against this; and, moreover, it becomes difficult to diagnose the lower, *practically identical* patch, which cannot well be another tusk arising half-way down the trunk. The treatment of the "under surface of the trunk" is also urged in support of the author's identification. Does this refer to the lower reduplication of the "tusk" pattern? If so, its severe zonal restriction seems to involve a still further departure from realism.

In regard to the figure of the so-called "*mahout*," one requires some corroboration of the bare statement that this is a "characteristic turbaned *mahout*." The attitude of the figure scarcely reminds one of that usually assumed by *mahouts*; it may also be questioned whether the "turban" can rightly be designated by that specific term at all; and it would have been of interest if Prof. Elliot Smith had given his reasons for assuming that the "elephant goad" (even supposing that it is correctly rendered in the pictorial reproductions of the stela) bears any real resemblance to known forms of that instrument (Fig. 1, B).

On p. 27, in his criticism of Maudslay's suggestion that the animal represented is probably a tapir (a beast with which the Maya people were familiar), Prof. Elliot Smith says, "Nor again is it credible that a craftsman so highly skilled in modelling (as the artist who fashioned this stela must have been) could have made so indifferent a portrait of a tapir as this." But it must be borne in mind that this craftsman's skill was largely applied to the production of a decorative and symbolic design, and that when symbolism is subjected to decorative embellishment, there is no limit to the conventionalisation of even a perfectly *well-known* animal form. The treatment in art of the Rhinoceros Hornbill in Borneo, and of the Wreathed Hornbill in New Ireland, affords good examples of grotesque and unrealistic elaboration of familiar bird-forms; while the zoomorphic designs in the composite totemistic art of N.W. America, or the highly conventionalised renderings of the human form in New Zealand, the Hawaiian Islands, and elsewhere, illustrate the play of fancy in what might have been realistic art, since the true forms were familiar enough and the craftsmanship was of a high order.

It seems probable that the so-called "elephant" figures on stela B are designs which are not only symbolic and decorative, but have been arrived at by a fusion of attributes derived from different prototypes. Earlier representations of macaws, cephalopods, tapirs, or other indigenous animals may well have contributed elements in the evolution of this complex hybrid design. Such examples of composite themes are very frequent in zoomorphic and other art designs, and the results are often as striking and unexpected as is the superficial resemblance to an elephant noticed in the Copan carvings. Once the departure from realism has reached a fairly advanced stage, the process of conventionalisation would tend to become accelerated, and the original prototype or prototypes may rapidly become almost unrecognisable. Moreover, the great exaggeration of some special feature in a once more or less realistic design, with a correlated diminution and obscuring of other features, is a common result of elaboration for decorative purposes. The semblance of an elephant's trunk, for example, might easily arise from some hypertrophied portion of a totally different zoomorphic *motif*.

What is needed before a final diagnosis of these Copan carvings can be arrived at, is an intensive comparative study of the art of the Mayas, and a collation of all those designs which appear to be related to the "elephant" figures. In this way the true affinities of the latter might be established through linked series of variations. Until this can be done, the real genesis and evolution of the "elephant" designs in the New World will remain obscure and debatable. In the long run, possibly, Prof. Elliot Smith's hypothesis may prove to be justified, but that stage has by no means yet been reached, and, in spite of his confident and over-emphatic assertions, his case cannot be accepted as proven. In the meantime he has furnished a treatise which conveys a direct challenge, and has brought together and, in his own way, ably urged a mass of evidence in support of his diagnosis.

The book is worthy of serious consideration as a contribution to a debate upon a complex subject. Although in many ways attractive and stimulating, the volume shows evidence (in misprints, premature assumptions, and other blemishes) of having been produced hastily and under the influence of a dominating theory, which has militated somewhat against calmly critical and unbiassed treatment of the theme. The illustrations are numerous and for the most part clear, and the details which have been brought together and have been marshalled with debating skill will prove of much value in the further investigation of an interesting problem, which must still be regarded as in a "fluid" state.

Studies in Engineering History.

The Newcomen Society for the Study of the History of Engineering and Technology. Transactions, vol. 3, 1922–1923. Pp. xii+140+21 plates. (London: Science Museum, South Kensington, 1924.) 20*s*.

THE new volume of the Transactions of the Newcomen Society fully maintains the high standard reached in the two previous volumes. As studies in engineering history, the various contributions shed new light on matters of importance in industrial history, while the range of subjects treated will make a wide appeal. The principal contents of this volume consist of six papers read before the Society. The first of these is a sketch of the work of Simon Goodrich, who for many years held an important post as the mechanical engineer of H.M. Dockyard, Portsmouth. Making use of a mass of material deposited at the Science Museum nearly fifty years ago, Mr. Forward traces the connexion of Goodrich with Sir Samuel Bentham, the elder Brunel, Henry Maudslay, and other engineers of the time. Goodrich was assistant to Bentham in 1799 when the first steam engine at Portsmouth was installed for pumping at the docks. He also supervised the erection of Brunel's famous block-making machinery made by Maudslay and brought into use a short time before the battle of Trafalgar. The Navy at that time wanted more than 100,000 blocks a year. So far Mr. Forward has only given us the career of Goodrich up to 1805, but as he held office until 1831 the remaining documents should bring to light much of very great interest.

Mr. Rhys Jenkins has already contributed to the Transactions a paper on the iron industry, and we now have a sketch of the early history of steel-making in England. The period covered is roughly 1500 to 1750, that is, until about the time Huntsman introduced the manufacture of cast steel. Mr. Jenkins's researches have had very fruitful results, for he is able to show that the cementation process originated in England about the beginning of the seventeenth century. As the president of the Society remarked in the discussion, "it was flattering to think that, to the puddling and the Bessemer process they might now add the cementation process as being of English origin." As an appendix to his paper the author gives some transcripts from some books of accounts relating to the iron and steel works of Sir Henry Sidney in Sussex and Kent in the sixteenth century.

The three succeeding papers refer to widely different matters. Mr. Titley gives what might almost be called "The Natural History of the Windmill"; Mr. G. P. Baker is the author of a paper on Indian cotton prints and paintings of the seventeenth and eighteenth centuries, while Mr. Brownlie gives a striking review of the early history of the manufacture of coal gas. The industry, which had its birth in a small house in Redruth, has now grown into a key industry employing more than 150,000 men. Mr. Brownlie tells us that the first gas water-heater was made so long ago as 1825, and the gas stove was patented by Edwards in 1849. Modern developments of these most useful appliances date, however, from about 1890.

The last of the papers is by Mr. J. E. Hodgson on "Sir George Cayley as a Pioneer of Aeronautics." Though Cayley's name does not appear in the "Dictionary of National Biography," he must not be classed among the forgotten worthies. He was a country gentleman of the North Riding of Yorkshire, where he was born in 1773 and where he died in 1857. A man of the type of Edmund Cartwright, his claim to fame rests on his writings and experiments on mechanical flight and navigable balloons. Mr. Orville Wright indeed says that Cayley's articles in *Nicholson's Journal* of 1809–10 "show an understanding of the subject of aerodynamics hardly exceeded by any one except Lilienthal during the rest of the century." When Henson proposed in 1843 to construct an aeroplane of 150 feet span, it was Cayley who suggested that a better design would be to use three superimposed planes of far less span. Cayley's ideas regarding airships were also sound.

Besides these papers the volume under notice has a report of Sir Frank Baines's lecture to the Society on the preservation of historic buildings, and an account of Savery's work on the steam engine, by Mr. Jenkyns, being an amplified reprint of a paper contributed some years ago to the Devonshire Association; and also an hitherto unpublished letter from Faraday to Ampère preserved in the Staatsbibliothek at Berlin. The letter is dated 1821, the year Faraday made his memorable discovery of electro-magnetic rotation.

Huia Onslow's Life and Work.

Huia Onslow: a Memoir. By Muriel Onslow. Pp. viii+247+5 plates. (London: E. Arnold and Co., 1924.) 12*s.* 6*d.* net.

IN the columns of NATURE Prof. R. C. Punnett wrote of Huia Onslow after his death in 1922 that his life "was the wonder of those who knew him," and of his achievement that, fine as it was, "finer still was the way in which it was won." This volume tells of the achievement and gives an indirect but none the less true and moving picture of the life.

The account of Onslow's scientific work is clear and simple. He obtained notable results in several branches of science. In genetics he studied the inheritance of coat-colour in rabbits and mice, with particular reference to the microscopic distribution of pigment granules and to the phenomena of albinism. He also carried out a long series of investigations into the inheritance of wing-colour in Lepidoptera, more especially the heredity of melanism in a number of species of moths. He gave much time to the study of the brilliant iridescent colours of some insects, discovering, by means of an exceptionally careful microscopic technique, the existence of thin films of chitin over certain butterfly scales, either lying flat on one another (like the skins of an onion) or set on edge (like the ridges of a ploughed field). The iridescence of these scales was shown to be due to the interference effects of the thin films of chitin and air, and the colour could be abolished by immersing the scales in liquid of the same refractive index as chitin, so that the air was expelled. In iridescent beetles no such structures could be found, and Onslow concluded for various reasons that a thin film of substance showing selective metallic reflection was responsible for the colours.

Turning to another branch of knowledge, Onslow was jointly responsible (with S. W. Cole) for the working out during the War of a standard nutrient medium for bacteriological purposes, now widely used, and of a method for the differentiation of typhoid and paratyphoid strains. He was also interested in protein chemistry, and was successful in solving the difficult problem of the quantitative estimation of the amino-acid tryptophane in casein.

Perhaps the most significant of Onslow's researches were those in what must eventually prove a fruitful field—the borderland between biochemistry and genetics, where he was a pioneer. Here undoubtedly his thorough and patient investigation would have yielded triumphs had he lived longer, and here especially it is to be hoped that his lead may be followed and his results extended.

One line of investigation concerned the chemistry of coat-colour in rabbits, more especially of dominant and recessive whiteness. It had been suggested that the melanin pigments present in hair were formed by the oxidation of the amino-acid tyrosine through the action of the enzyme tyrosinase. Onslow showed that extracts from the skins of coloured rabbits contain tyrosinase and form pigment when mixed with a solution of tyrosine, while extracts from the skins of albino rabbits (recessive white) do not form pigment from tyrosine. Albinism would thus appear to be due in this case to the absence of tyrosinase. In rabbits carrying a dominant factor for whiteness, on the other hand, extracts of the skin contain a substance which inhibits the production of pigment from tyrosine by extracts from coloured skins. The foundation of a genuine chemical explanation of one phenomenon of Mendelian heredity was thus established.

Again, Onslow found that the production of melanin in the black markings on the wings of the Cabbage White butterfly had a similar cause. There is no black pigment in the pupal stage; when there is access to the air, tyrosine is oxidised to melanin by the action of tyrosinase. The distribution of pigment was shown to be due to the localisation of the precursor, tyrosine, not of the enzyme.

A third example of this kind of work was the study begun by Onslow of the inheritance of a metabolic peculiarity of the Dalmatian hound, and the correlation of this with the inheritance of coat-colour, etc.

For a man of only thirty-one years this would have been a remarkable enough record of achievement even had he been in normal health and circumstances. Yet, at the age of twenty, he received an injury to the spine, while diving, which rendered him completely paralysed below the waist, and only left him partial use of his hands and arms. For the remaining eleven years of his life he never left his couch and was often in pain and sometimes in danger. As an undergraduate he had been interested widely rather than deeply in many activities, in science, literature and art, in mountaineering, hunting, and other sport, and the accident seemed not to check but rather to concentrate his energies. Resolutely and courageously he took up the serious studies which led to the work outlined above. He conquered untold difficulties by his immense determination, learning to perform many details of chemical manipulation himself, and becoming a master of microscopic technique and an expert draughtsman. He kept very wide interests outside his scientific work, and was the centre of a large circle of friends. In 1919 he married the fellow-worker in biochemistry and genetics to whom we owe the present volume. It will be valued by many who were his friends, and it may confidently be hoped that others also will be led by it to draw inspiration from a life at once tragic and triumphant.

Our Bookshelf.

Die Biogenen Amine und ihre Bedeutung für die Physiologie und Pathologie des pflanzlichen und tierischen Stoffwechsels. Von M. Guggenheim. (*Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere*, Band 3.) Zweite umgearbeitete und vermehrte Auflage. Pp. viii+474. (Berlin: Julius Springer, 1924.) 4·80 dollars.

THE term "Biogene Amine" is employed by the author to denote a somewhat heterogeneous group of organic compounds occurring in the plant and animal world, the only common property of which is the possession of one or more amino, or substituted amino-groups. In the author's opinion, all the amines in question may be produced in one of two ways; either by synthesis from simple substances or by the break-down of more complex compounds; as an example of the former mode of origin he quotes the production of primary amines from ammonia and alcohols or aldehydes with subsequent conversion into secondary and tertiary bases, etc., while the production of amines by decomposition is exemplified by the hydrolysis of phosphatides, proteins, or the de-carboxylation of amino-acids such as is commonly brought about by micro-organisms. The first chapter contains a description of the general methods employed for the isolation of such amines, together with an account of their general properties. The rest of the work is divided up into ten sections, nine of which are devoted to compounds of known composition, while the tenth deals with substances of unknown constitution such as the active principles of the pituitary and thyroid glands. In the section dealing with phenylalkylamines, attention is directed by means of structural formulæ to the comparatively close relationship subsisting between phenylethylamine and a number of complex alkaloids indicating a possible mutual inter-relationship between these substances.

The volume contains a quantity of information concerning the sources, mode of preparation, physical and chemical properties, and, where possible, the biochemical and pharmacological significance of the substances discussed. Not the least valuable feature is the very complete list of references at the end of the book, which covers the literature of the subject up to the beginning of 1923. For the verification of these references and much other valuable assistance the author gratefully acknowledges his indebtedness to Prof. Barger, of the University of Edinburgh.

The Specific Heats of Gases. By Prof. J. R. Partington and W. G. Shilling. Pp. 252. (London: Ernest Benn, Ltd., 1924.) 30*s.* net.

PROF. PARTINGTON'S book is remarkable in that, instead of dealing generally with the properties of gases, it selects for fuller treatment the single property of specific heat. In the case of steam, tables of fundamental data are available, in which the numerical results have been subjected to a critical sifting during a period of many years and are at least approximately accurate. No similar trustworthy data for gases have been available hitherto, and the object of the present volume is to supply this gap. This has been done in part by means of new determinations by the authors, but also by a critical survey of existing data, many of which have been recalculated from the experimental figures in order to bring them all to a common basis. As a result of this survey the eleven pages of original data of Table A are reduced to a single Table B of molecular heats at atmospheric pressure, whilst the data of Table C, giving values for every 100° from 0° to 2000° and 2300°, occupy six pages.

Theoretical views are touched on only lightly, as they have been of no real service in predicting data, and can only with difficulty be reconciled with the figures already available. The book is not intended for beginners, and "the peculiar difficulties of the undeveloped mind" have not been considered in writing it; it is, in fact, intended as a reference book for specialists, and its construction is such that it will obviously be indispensable to all serious workers in this field for many years to come. The book is printed with unusually narrow margins, especially at the top of the page; this gives to the pages the novel appearance of a "high waist-line," and is not unattractive, whilst it obviously permits of a better utilisation of a given area of high quality paper.

Electricity and Magnetism for Advanced Students. By S. G. Starling. Fourth edition. Pp. vii+612. (London: Longmans, Green and Co., 1924.) 12*s.* 6*d.* net.

THE rapidity with which physical knowledge is extending at the present time must be a source of no small embarrassment to writers of the more advanced type of text-book. The progress in the subject of electricity during the twelve years which have elapsed since the publication of this book has been of such a fundamental character that it could not be relegated to additional chapters or appendices. A considerable amount of revision was thus necessary if the new matter was not to be too obviously grafted on the original. It is good to find that Mr. Starling has recognised this necessity, and congratulations are due to him on the result, for the book is now up-to-date, yet still homogeneous. He could not, of course, attempt to deal exhaustively with the electron theory and other modern developments, but he has given a very useful survey of them which will serve as an excellent introduction to more detailed study, the more so as it covers the widest possible field. For example, considerable space is devoted to the question of atomic structure, and an account of Bohr's theory of the hydrogen spectrum is given. In connexion with the latter it may be pointed out that the generalised quantum specification was given by Sommerfeld in 1916 (not 1911 as implied), but had been previously proposed by W. Wilson (1915).

Altogether about one-fifth of the book is concerned with the newer developments of the subject. There is no doubt that the time was ripe for this revision, and the present edition is sure of an appreciative reception from a wide circle of students.

The Continent of Europe. By Prof. Lionel W. Lyde. Second edition. Pp. xv+456. (London: Macmillan and Co., Ltd., 1924.) 10*s.* net.

THE revised edition of Prof. Lyde's well-known volume is in large part a reprint, with slight verbal changes, of the original work, but the chapters dealing with eastern Europe have been recast and rearranged. Here

and there statements have been left that now require emendation, *e.g.* the sovereignty of Bosnia (p. 146), and there are a few surprising omissions, *e.g.* the Murman railway. The treatment of Europe by political unities has many advantages except where the principle of self-determination has been allowed to run riot in the creation of small States. In such cases Prof. Lyde has not literally adhered to the system.

The book retains its merits and some of its defects. It is not a text-book to which the student can turn for full treatment of any part of Europe, and it contains many statements that need to be tested in the light of facts and close examination. In tracing causal relationships the author not infrequently jumps steps in his argument, and this does not make the book any too easy to read. On the other hand, he is never commonplace and never wearies his readers by telling him the obvious. Every page is stimulating, unexpected, and provocative. Prof. Lyde's picture of Europe is impressionist and extraordinarily vivid. To an uncritical mind the book might be misleading, but the intelligent reader with some knowledge at his command should find its ideas and suggestions invaluable in a study of the complex human problems of Europe.

The lack of coloured maps, which were in the original edition, is no loss. A folded black and white political map of central Europe has been added. The sketch maps and diagrams have been retained with little change. In a few cases revision would not be amiss.

Morphologie générale. Membres et ceintures des vertébrés tétrapodes : Critique morphologique du transformisme. Par Prof. L. Vialleton. Pp. viii + 710. (Paris : Gaston Doin, 1923.) 60 francs net.

PROF. VIALLETON is the leader in France of the school of modern transformists who believe in the Darwinian explanation of the evolution of genera and species by the process of the natural selection of small variations, but consider that the larger groups have arisen by a more rapid process of profound mutation. To illustrate this doctrine he presents us with a handsome and very useful monograph on the limbs and girdles of the cheiropterygial Vertebrata. The descriptions given of the various bones and articulations are clearly written, and the numerous illustrations throughout the text are excellent. As a work of reference for students of osteology this monograph is invaluable.

Students of morphology will naturally turn with special interest to the chapters dealing with the theoretical conceptions of the origin of the girdles and of the pentadactyle appendages, but they will be disappointed to find that there is no reference to Graham Kerr's important external gill hypothesis or to Goodrich's brilliant researches on the nerve supply of the limbs and his support of the lateral fold theory. The author seems to favour a theory expounded by A. C. Geddes in 1912, which is based on the supposition that there is an anterior and central region of the body of Vertebrata which is not and never was metamerically segmented. Such a theory is, no doubt, acceptable to the modern transformist, but it will be difficult to persuade the morphologists of the older school that the structure of the Vertebrata as we know them is not founded on a completely metamerically segmented ancestral type.

The New Theories of Matter and the Atom. By Prof. Alfred Berthoud. Translated from the French by Eden and Cedar Paul. Pp. 259. (London : George Allen and Unwin, Ltd. ; New York : The Macmillan Co., 1924.) 10*s.* 6*d.* net.

PROF. BERTHOUD'S book is very attractive both in its literary style and in the form in which it has been issued by the publishers. The scope of the book, dealing as it does with electrons, X-rays, radioactivity, isotopism, quanta and atomic structure, is familiar, so that the way in which the matter is presented is of more importance than the table of contents. Whilst it does not shirk the mathematical method of exposition, the book is eminently suitable for the reader whose knowledge of mathematics is too small to enable him to follow the more technical treatises of some of the physical writers.

As a professor of physical chemistry, the author is well acquainted with the limitations of the typical chemist in this direction, and the style and value of his book can therefore be expressed clearly by saying that it describes the physical developments of the present day in a form in which they can be understood and appreciated by chemists. This statement implies that the book is also suitable for the general scientific reader. The fact that most of the pages contain only a single fount of type, broken here and there by a series of cross-headings and varied only by a sparing use of italics, has the happy effect of creating the impression that the volume is not a mere text-book, to be used when "cramming" for an examination, but a book to be read and enjoyed in an arm-chair. It can therefore be heartily commended to those who read for pleasure, as well as to those whose reading is dictated by more urgent necessities.

Les Protéines. Par Jacques Lœb. Traduit de l'Anglais par H. Mouton. (Nouvelle Collection scientifique.) Pp. viii + 243. (Paris : Félix Alcan, 1924.) 10 francs.

THE original volume of which this is a translation is already familiar to English readers, and there is therefore no need to recapitulate the author's views with regard to the significance of the Donnan theory of membrane equilibria in explaining the colloidal behaviour of protein solutions. In his preface to the French edition, dated October 1922, the author stated that the work was to appear in two parts, the first part being devoted to the stoichiometric and colloidal properties of proteins and the second to the theory of colloidal properties.

The present volume, published in 1924, after the author's demise, represents the first half only of the complete work, the translation of the second half not yet being completed. It contains two new chapters dealing respectively with the electric charge and stability of suspensions and emulsions, and the crystalloidal character of the solutions of certain natural proteins in water. In the latter chapter the author discusses the question whether proteins are kept in solution by the same forces which determine the solubility of crystalloids in water or by the electric double layers which keep particles of oil in suspension in water, and arrives at the conclusion that the conditions

vary with different colloids. The translation is on the whole good, but, owing to an extraordinary oversight, the title of the second chapter is translated as being a quantitative proof, whereas in fact it appears in the original English edition as a qualitative proof.

Siam. By W. A. Graham. Third edition. (In 2 vols.) Vol. 1. Pp. xii + 396 + 45 plates. Vol. 2. Pp. viii + 320 + 69 plates. (London: Alexander Moring, Ltd., 1924.) 42*s.* net.

IT is surprising that Siam should be comparatively little known in Great Britain, notwithstanding the part played by Englishmen in its recent development under two monarchs of marked European sympathies, one of whom indeed had been educated in England. Mr. Graham's "Siam" should do much to dispel this ignorance, as well as to arouse interest in a country which should repay investigation. Written originally as a short handbook, it has now expanded into two volumes to cover the developments of the last twelve years. From the scientific point of view, Siam is almost virgin ground. For example, except for a few partial investigations, the botany has scarcely been studied, and apart from Skeat and Blagden's investigations of the wild tribes in the south, ethnological data are practically not available. Such conclusions as Mr. Graham has to offer are really based upon material drawn from the adjacent areas of Further India. Setting aside the drawbacks inevitable in view of the fragmentary state of our knowledge in certain departments, Mr. Graham's book is an informative account of the country and its resources, and of the manners, customs, beliefs, and social organisation of its people. In the chapter on music and the drama, the reference to the interesting and characteristic dances is disappointingly brief.

The Home of an Eastern Clan: a Study of the Palaungs of the Shan States. By Mrs. Leslie Milne. Pp. viii + 428 + 20 plates. (Oxford: At the Clarendon Press; London: Oxford University Press, 1924.) 16*s.* net.

MRS. MILNE'S account of the social life and customs of the Palaungs, a people living in a northern Shan State, but quite distinct from the Shans and belonging to the Mon Kmer group, is the outcome of her linguistic researches. When she first came into contact with them in 1906, their language had been little studied. In the course of several visits to their country, she compiled a dictionary, and in acquiring a vocabulary took her informants through every stage of the ceremony or custom for which she wished to ascertain the associated groups of words. By pursuing this method, she not unnaturally acquired a good deal of information bearing on the psychology, the social life and religion of the people. This information is the subject matter of the present book. The reading public, whether it apprehends the immense labour which has gone to the making of it or not, will at any rate appreciate the result. Mrs. Milne has produced a most readable and entertaining book which at the same time is of considerable scientific value. A welcome feature is that, as an outcome of her method, she deals very fully with the early stages of the life of the individual—a subject which frequently is very inadequately treated in the description of a primitive tribe.

Laboratory Experiments in Practical Physics: to Accompany the revised edition of Black and Davis' "Practical Physics." By N. Henry Black. Pp. ix + 245. (London: Macmillan and Co., Ltd., 1924.) 4*s.* 6*d.* net.

THIS is a revised and enlarged version of the author's Laboratory Manual published in 1913. In addition to some fifteen new experiments, introductory paragraphs have been prefixed to each experiment in which principles and practical applications are discussed. While these often provide interesting information (*e.g.* that every Ford automobile has sixteen permanent magnets bolted to its fly-wheel), one could wish that some attempt had been made instead to give a logical and connected development of the subject. No doubt the academic method has its limitations, but it is possible to progress too far in the opposite direction, and the practical or utilitarian method, if carried far enough, may retain little of real educational value. However, the latter method seems to be enjoying a considerable vogue in the United States at the present time, and, judged by the appropriate standards, the book is probably an excellent one. It is certainly clearly written and carefully compiled, but it is too distinctively American in outlook to be likely to appeal generally to students in Great Britain.

Examples in Chemistry. By Dr. William W. Myddleton. Pp. viii + 134. (London: Methuen and Co., Ltd., 1924.) 3*s.*

DR. MYDDLETON has produced a very useful and attractive set of examples for calculation suitable for use in schools and, with a little supplementing, for Intermediate Science students. There are no sections explaining the methods of calculation, and the book consists entirely of examples for exercise. This is in some ways an advantage, since the book can be used by teachers who prefer different methods of dealing with the subject. The questions will bring to the notice of students who work through them a number of points not often found in such books, and it is clear that the questions will fit in well with modern methods of teaching the subject. The book can be recommended as likely to prove very useful both to teachers and students. Answers to all the questions are given.

Applied Chemistry. By Prof. Ira D. Garard. Pp. vii + 496. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1924.) 15*s.* net.

A STUDENT who has graduated with first-class honours in chemistry from one of the universities may be expected to know very little about the chemistry of the common things of life. The composition of cheese, bread, leather, paints and varnishes, inks and boot polish will generally be unknown to him. The chemical changes taking place during the cooking and digestion of food will probably be less well known than those involved in "organic preparations." Prof. Garard's book, which does not treat of "Applied Chemistry" in the sense understood in Great Britain, will assist many chemical students to a better understanding of things which are mysteries to them, and is an interesting though rather superficial supplement to the standard treatises.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Gravity Observations on the Indian Ocean and the Results of their Isostatic Reduction.

FOR years geodesists have anxiously awaited the securing of accurate gravity observations at sea for use in the determination of the shape of the earth and in testing the theory of isostasy. The gravity observations made at sea by Hecker, Briggs, and Duffield were a good step forward in this important work, but their results were not of the required degree of accuracy. They did, however, encourage us to believe that the problem would be solved in the not distant future.

Geodesists felt that the longed-for event had materialised when they read the communications from Dr. J. J. A. Muller, published in recent volumes of NATURE (September 15 and December 1, 1923; March 1 and May 3, 1924).

Dr. Muller reported on the determination of gravity at sea by Dr. F. A. Vening Meinesz, of the Geodetic Commission of Holland. Dr. Meinesz's work was done on a submarine, and the observations were made with the pendulum apparatus employed in the determination of gravity on land. I communicated with Dr. Muller, and also with Dr. Meinesz, and asked for further details in regard to the gravity work than had appeared in the letters in NATURE. I was given interesting and valuable information by them, but Dr. Meinesz will no doubt soon publish full accounts of his work, and it would be inappropriate to place in this note all the information that was furnished to me. I shall, however, discuss the isostatic reduction of five stations in the Indian Ocean for which Dr. Meinesz furnished the observed values.

Dr. Meinesz informed me that four pendulums were swung simultaneously in the same case or container in order to eliminate the effects of the motion of the submarine in which the pendulum apparatus was mounted. While observations were made, the vessel was submerged from 10 to 25 metres below the surface, in order to avoid the motion that would be imparted by waves if it were at the surface.

So far as I am aware, Dr. Meinesz is the first observer to use the pendulum apparatus on a boat, but it may be interesting to note that in a paper by me, entitled "The Bearing of Geodetic Investigations on the Geological Structure of the Pacific," presented at the first Pan-Pacific Scientific Congress conference held under the auspices of the Pan-Pacific Union at Honolulu, Hawaii, in August 1920, the following statement was made:

"It is hoped that a satisfactory apparatus may be devised for determining the intensity of gravity at sea, using special vessels or commercial vessels. There are several types of apparatus in existence, but no one of them gives results of sufficient accuracy for the study of isostasy. The writer suggests that it may be possible to obtain a fair value of the intensity of gravity at sea by the use of the land apparatus properly mounted on a vessel. The apparatus would have to be swung in double gimbals and should be placed near the point of minimum translation resulting from the pitching and rolling of the vessel."[1]

[1] Proc. First Pan-Pacific Scien. Conf., Honolulu, Hawaii, 1921, Spec. Pub. No. 7, Bishop Museum, p. 885.

It was with great satisfaction that I read that Dr. Meinesz had accomplished the accurate determination of gravity at sea with the use of pendulums. No doubt he arrived at the conclusion that the pendulum could be used independently of my suggestion in 1920.

Dr. Meinesz informed me that, so far as observations aboard the ship were concerned, the mean error from the observations alone were only one or two parts in 5 million in calm weather and rarely more than ten parts in rough weather. He feels that there should be better control of the temperature of the pendulum during the observations and of the rates of the chronometers.

The submarine was submerged at each station for 15 or 20 minutes, and the rates of the chronometers were dependent upon radio-signals received each day. It seems to me that in the work on a ship the principal difficulty arises from the fact that it is difficult to get a sufficiently accurate time interval from a chronometer which is only compared once a day with radio-signals. It would be better to have arrangements made with a radio-station to have accurate time-signals sent out each hour during the time gravity is being observed at sea. In this way, somewhat greater accuracy would be obtained.

The thought has occurred to me that a tuning-fork may possibly be used as the time-piece in getting accurate gravity observations with the pendulum, both on land and at sea. The tuning-fork would, of course, have to be made of material that would be only slightly affected in its elastic properties by changes in temperature, or some method would have to be devised which would enable one to determine with extreme accuracy the temperature of the fork. The material of the fork would necessarily have to possess constant elastic properties or values for any given temperature. If such a fork could be devised, a few oscillations of the pendulums compared with vibrations of the tuning-fork would give a value for the period of the pendulum. The tuning-fork, of course, would have to be standardised and rated at the base station.

With a letter dated August 2, 1924, Dr. Meinesz furnished the data given below for 13 stations in the Indian Ocean or in its ports:

OBSERVATIONS IN THE INDIAN OCEAN.

	Latitude North.	Longitude East of Greenwich.	g (unreduced).	$g_o'' - \gamma_o$.
1	11° 54′·5	53° 03′·5	978·286	+0·032
2	10 02	55 25	978·184	−0·006
3	7 57	61 53	978·136	+0·002
4	7 53	65 58	978·111	−0·021
5	7 56·5	68 46	978·102	−0·032
6	8 06	72 48	978·113	−0·024
7	7 20	77 28	978·099	−0·020
8	6 56·5 (Harbour of	79 51 Colombo)	978·118	+0·012
9	5 50·5	80 12	978·168	+0·080
10	5 32	80 12·5	978·014	−0·069
11	5 44	87 07	978·065	−0·020
12	6 02·5	92 50	978·024	−0·068
13	5 53·5 (Harbour of	95 19 Sabang)	978·181	+0·097

The values for g in the table above were reduced for the effect of the speed of the vessel during the observations, which lessened or increased the centrifugal force due to the earth's rotation. In computing the Bouguer anomalies shown in the last column, Dr. Meinesz applied a correction to take account of the depth of the submarine below the surface of the water.

It would have been interesting if isostatic reductions could have been made for all of these stations, but this was impossible in the short time that was available. However, reductions were made at the office of the U.S. Coast and Geodetic Survey by Mr.

C. H. Swick, Chief of the Section of Geodesy and Astronomy of the Division of Geodesy of the Survey, for stations 2, 3, 4, 5 and 11 of the above list. The results of Mr. Swick's work are shown in the following table:

PRINCIPAL FACTS FOR GRAVITY STATIONS IN THE INDIAN OCEAN ESTABLISHED BY DR. MEINESZ, OF HOLLAND.

No. of Station.	Latitude ϕ.	Longitude λ.	Depth, fath.[1]	γ_0.	Correction for Submergence.	Correction for Topog. and Comp.	Computed Gravity at Station (g_c).	Observed Gravity at Station (g).	Isostatic Anomaly.	
									$(g-g_c)$.	$(g-g_c-0{\cdot}008)$.
2	10° 02′	55° 25′	2300	978·187	+0·005	−0·016	978·176	987·184	+0·008	0·000
3	7 57	61 53	2400	978·129	+ ·005	− ·013	978·121	978·136	+ ·015	+ ·007
4	7 53	65 58	2400	978·127	+ ·005	− ·010	978·122	978·111	− ·011	− ·019
5	7 56	68 46	2400	978·128	+ ·005	− ·017	978·116	978·102	− ·014	− ·022
11	5 44	87 07	2200	978·081	+ ·005	− ·008	978·078	978·065	− ·013	− ·021
							Mean with regard to sign . . .		−0·003	−0·011
							Mean without regard to sign . .		·012	·014

[1] Depths were estimated from soundings shown on charts Nos. 854*a* and 854*b* of the Hydrographic Office of the United States Navy.

These five stations were selected because they were in the open ocean where the depths of the water vary from 2200 to 2400 fathoms, or from 13,200 to 14,400 feet. In metres, the depths are from 4025 to 4390.

The computed value at the station is based on the well-known Helmert formula of 1901, in which the first term is 978·030.

The values for g_c were corrected for the effect of the topography of the whole world and its compensation. The combined effect of these two are given in column No. 7.

In the column headed "$g-g_c$" are the isostatic anomalies based on the Helmert formula. It will be noticed that the largest anomaly is 0·015 dyne. The mean of the five anomalies with regard to sign is only −0·003, while the mean without regard to sign is only 0·012.

My formula, which is given in Special Publication No. 40 of the Coast and Geodetic Survey, is the same as the Helmert formula except that the first term is 978·038. The isostatic anomalies based on this formula are shown in the last column of the above table. With this formula the mean anomaly with regard to sign is −0·011, and the mean without regard to sign is 0·014.

It is possible that the uncertainty of the observed values at Dr. Meinesz's stations is of the order of magnitude of the difference in the two formulas used.

These small anomalies, with and without regard to sign, for the five stations over deep water in the Indian Ocean, seem to indicate very clearly that the crust of the earth below the area covered by the stations is in a state of isostatic equilibrium that is very nearly perfect. They also indicate that there is no large longitude term as advocated by Helmert and shown in his 1915 formula. That formula was discussed by me in Special Publication No. 99 of the Coast and Geodetic Survey.

It would appear from the results given above that Dr. Meinesz has made a valuable contribution to geodetic science, and that he has added another piece of evidence in favour of the theory of isostasy. Let us hope that he will be able to make isostatic adjustments for all of his stations in the Indian Ocean, the Mediterranean Sea, and in the Atlantic, and let us hope also that Dr. Meinesz will be able to continue his valuable work, and that geodetic organisations in other countries may embark on this new line of geodetic observations.

Polarisation of Resonance Radiation in Magnetic Fields.

WOOD and ELLETT have shown that weak magnetic fields may greatly affect the polarisation of resonance radiation, the nature of the effect depending upon the relative orientation of the magnetic field and the electric vector of the exciting light. In the absence of a magnetic field, the resonance radiation emitted in the direction of the axis of Z by an atom excited by a beam of light parallel to the X axis and polarised with its electric intensity parallel to the Y axis is found to be more or less completely polarised, the per cent. polarisation, defined as $\frac{E_y - E_x}{E_y + E_x}$, varying from 90 in the case of mercury to 16·3 for sodium excited by both D_1 and D_2. The effect of a magnetic field parallel to the Z axis is to reduce this polarisation—the law of decay being quite accurately represented by an equation of the form

$$\frac{E_y - E_x}{E_y + E_x} = P_0 e^{-KH}.$$

The writer has recently observed that in D line resonance radiation with the magnetic field, the azimuth of the maximum polarisation is no longer parallel to OY, but is rotated in the direction of the Larmor precession. The angle of rotation is not directly proportional to the intensity of the field, probably because the interval between absorption and emission is not the same for all atoms. With D_2 resonance radiation of sodium, a field of 3·6 gauss rotates the azimuth of maximum polarisation 16·5°, and a field of 13·5 gauss rotates it 21°. Beyond this point, the azimuth of maximum polarisation cannot be determined with accuracy because of the decrease in polarisation due to the field. This rotation of the azimuth of maximum polarisation appears to be due to an actual rotation of the resonating atom. At first, it appeared that it might be due to rotation of the plane of polarisation by the layer of sodium vapour between the resonating atom and the observer, but such is not the case, for the magnitude of the rotation is independent of the thickness and density of this layer.

These observations were made in sodium freed from hydrogen as completely as possible and at temperatures of 85° to 95° C., where the vapour pressure of the sodium is so low that the time of a free path is large compared to τ, the average interval between absorption and re-emission.

It may be pointed out that by making suitable assumptions as to the manner of distribution of the time intervals between absorption and emission, we may calculate τ from the magnitude of this rotation.

E. Gaviola and P. Pringsheim have recently shown (*Zeit. f. Physik*, 25, 367, 1924) that the polarisation of sodium resonance radiation is due entirely to D_2, as one would expect from the character of the Zeeman levels involved. Using a different method, I made similar observations independently at about the same time (April and May of this year). The D lines were separated in the light from the exciting source by means of Prof. Wood's rotary dispersion scheme, and resonance radiation excited by either D_1 or D_2 alone.

D_2 alone shows polarisation. In addition, it may be pointed out that the $2p_1 - 2s$ and $2p_2 - 2s$ thallium lines show no polarisation in resonance radiation, as would be expected, since the *s* levels are above, while $2p_2 - 2d_2$ shows strong polarisation. The first and second doublets of the principal series of cæsium and potassium show polarisation in resonance radiation, due presumably to the more refrangible member of the doublet in each case.

For certain types of spectral lines, the theory of the anomalous Zeeman effect shows that resonance radiation excited in a magnetic field by plane polarised light must itself be partially polarised, because of the absence of certain components of the Zeeman pattern (Foote, Ruark and Mohler, J.O.S.A. and R.S.I., 7, p. 415, 1923.) I have found that in the *absence* of a magnetic field, lines of this type, *e.g.* $1s - 2p_1$ of sodium, $1s - 2p_2$ of mercury, $2p_2 - 3d_2$ of thallium, show polarisation; while those in which all components of the Zeeman pattern are to be expected, as $1s - 2p_2$ of sodium, $2p_1 - 2s$ and $2p_2 - 2s$ of thallium show no polarisation either with or without the field.

This work was done at the Johns Hopkins University, and is being continued at the Bureau of Standards.

Heterogeneous Catalysis.

PROF. H. S. TAYLOR has pointed out to us that it is not clear from our paper on the heats of adsorption of oxygen on charcoal (Blench and Garner, J.C.S., 1924, 125, 1288) that the values were expressed in kgm.-cal. and also that we had not discussed the bearing of these results on the mechanism of heterogeneous catalysis. The latter point had, however, been reserved until further and more accurate data had been obtained, but, as it appears to be a matter of general interest, I propose to discuss it briefly in this letter.

The position, mode of orientation, and energy content of the atoms forming the surface of a homogeneous catalyst will very largely determine the part they play as individuals in the catalytic process, and it is not unlikely that a comparatively small number of the total atoms on the surface are the active agents in promoting the chemical change. This view is supported by the very large differences in energy content which have been shown to exist among the atoms on a carbon surface.

On admitting oxygen to an active carbon surface, heat is liberated which is due partly to the formation of carbon monoxide and dioxide and partly to the formation of an adsorption complex, C_xO_y. By allowing for the heats of formation of the two gases formed, it is possible to obtain a value for the "heat of formation" of the complex C_xO_y, which does not necessarily represent solely the heat liberated in its formation, but also includes any decrease in energy of the surface due to the liberation of the two gases. This heat of reaction, expressed in kgm.-cal./gm.mol.O_2 adsorbed, was often greater than the heat of formation of carbon dioxide. It decreased as the amount of gas admitted increased, and increased with the temperature of adsorption. The heat liberated ranged from 52 kgm.-cal. at 18° to 224 kgm.-cal. at 450° C. for the first small quantities of oxygen admitted. On subsequent admission of oxygen lower values than these were always obtained. These heats of reaction are of the same order as the energy liberated in the formation of the C-C linking as deduced from the heat of sublimation of carbon. Thus the valency of the surface carbon atoms is very far from being saturated by neighbouring carbon atoms.

The ratio of the oxygen atoms adsorbed to those giving rise to carbon monoxide and dioxide decreases with increase in temperature; in other words, a proportion of the atoms adsorbed at the low temperatures is liberated as gases at the high temperatures. Thus the differences between the heats of adsorption at two temperatures must be due to different selections made from the carbon atoms on the surface, and hence are an indication of the very widely differing energy contents of these atoms. The oxygen atoms which remain on the surface at any one temperature will be to a large extent those held by a number of carbon atoms, while those adsorbed on exposed carbon atoms, which are less tightly bound to the surface, will give rise to the oxides of carbon. Thus the high heats of adsorption are not due solely to the energy liberated on combination of the oxygen atoms with the surface, but also to that liberated on the removal of the exposed carbon atoms, *i.e.* carbon atoms with a high energy content, from the surface. Both energies are undoubtedly very high compared with the heat of formation of carbon monoxide, but without further work it is difficult to decide between their relative importance. The most active atoms are, however, removed on the first admission of oxygen.

A point of difference between the reactions of carbon and oxygen and a catalytic reaction lies in the fact that the atoms of the catalyst do not leave the surface although their relative positions with respect to one another may change during the reaction. It is, however, clear that those atoms lying in an exposed position on the surface, by virtue of their high energy content, will play a large part in the chemical process. They will be the most likely to possess the energy necessary for promoting the trigger action of catalysis. Also it can be seen why the surface becomes increasingly effective with use. If part of the heat liberated during the heterogeneous reaction is absorbed by the surface, this may result not only in an increase in the total surface but also in an increase in the proportion of exposed atoms on the surface, *i.e.* an increased free energy of surface per sq. cm.

Seed Inoculation of Lucerne (*Medicago sativa*) and its Relation to the Motility of the Nodule Organism in Soil.

THE successful results that are being obtained in other countries from the inoculation of lucerne seed with the nodule organism (*Bacillus radicicola*, Beyerinck) have stimulated investigation of this subject in England. In this practice the details of the method used in the inoculation are of great importance. The method consists essentially in making a suspension of the bacterial culture in some liquid, and in using this suspension to wet the seed. In this way each seed is coated with a film of liquid in which the bacteria lie. There is evidence that after penetrating the tissues of the root the bacteria are unable to pass for any significant distance along it. Consequently, when the seed has germinated, the bacteria must progress or be carried through the soil in order to reach from the seed-coat to the various parts of the root system, where nodules are to be formed. A study of the factors affecting the motility

of the organism and its passage through soil has, therefore, an important bearing on the technique of seed inoculation.

A modification of Winogradsky's technique for staining bacteria in soil (1924, *Comptes rend. Acad. Sci.*, vol. clxxix. p. 367) has enabled the present authors to follow the passage of the nodule organism through sterile soil. It has been found that they will progress through light soil at an approximate rate of one inch in 24 hours, though the rate is affected by the soil texture. When a drop of water containing the bacteria in the rod stage is added to sterile soil, the spread of the organisms from the point of inoculation does not begin until after a considerable interval, and its commencement is accompanied by the conversion of a large percentage of the bacteria into cocci. If the inoculum consists of a suspension in milk, the bacteria begin to spread through the soil after a shorter interval. This is perhaps an explanation of the successful results obtained by using a suspension of the bacteria in skim milk for wetting the seed, a technique now practised in Scandinavia for inoculating lucerne. The effect of milk also emphasises how important is the nature of the liquid used in making the bacterial suspension for seed inoculation.

Bewley and Hutchinson (*Journ. Agric. Sci.*, 1921, vol. x. p. 144) found that the production of the motile coccoid stage of *Bacillus radicicola* was greatly stimulated by the presence of phosphates. The effect of inoculating sterile soil with a suspension of the bacteria in skim milk containing 0·1 per cent. soluble calcium phosphate, $CaH_4(PO_4)+2H_2O$, was therefore tested. It was then found that the spread of the organisms from the point of inoculation commenced almost immediately. It seemed probable that the use of a bacterial suspension in the above solution for wetting the seed would increase the chances of nodule formation by hastening the spread of organisms from the seed-coat, and thus increasing the volume of soil explored by them in a given time. Pot culture tests of seed inoculation were therefore made with lucerne, in which a bacterial suspension in a 0·1 per cent. solution of $CaH_4(PO_4)_2+2H_2O$ in skim milk was compared with a suspension in skim milk alone, such as is now in practical use. On averages of 10 parallel pots, increases in nodule numbers of 93 per cent. and 73 per cent. were obtained in two experiments by the addition of phosphate to the milk. There was also a favourable effect on the yield of the crop. The work is being continued and will be published in detail at a later date.

Capillary Action: Transpiration.

IF a capillary tube, A, Fig. 1, with a wedge-shaped cut in it at a distance of about 10 mm. from its upper end, at right angles to, and deep enough to make a breach in one side of its aperture, is lowered slowly into water the rising column of water pauses for an instant when it reaches the gap, which is necessarily higher than the surface of the water into which the tube is being dipped, and then leaps past it and rises to the top of the aperture.

When this tube is fixed in a cork as shown in Fig. 1; the cork inserted as a stopper into the mouth of a cylindrical vessel, B, containing water; the vessel, B, fixed in a circular piece of cork which acts as a stand for it; and a small sheet of thin blotting paper, *b*, drawn far enough into the cut to touch the thread of water in the aperture, the capillary tube acts the part of the stem of a plant, the blotting paper that of a leaf, and transpiration commences and continues uninterruptedly through the latter so long as the water lasts. A current of water flows up the aperture of the capillary tube and through the gap in it to the blotting paper from which it is evaporated continuously without creating any visible disturbance in the thread of water contained in that part of the aperture above the gap. As the surface of the water inside the vessel, B, is being lowered, air flows into the space above it through a fine capillary tube, *a*, which passes through the cork near the larger tube.

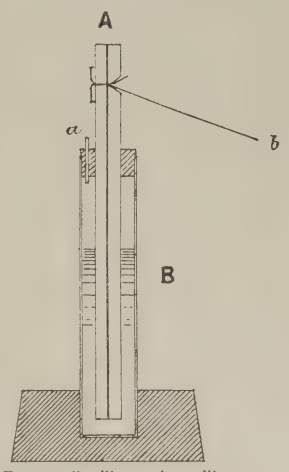

FIG. 1.—Capillary tube to illustrate transpiration. Half real size.

In an experiment with this apparatus carried out in May 1922, the dimensions of the sheet of blotting paper were 33 mm. by 43 mm. The edge of the sheet was drawn into the cut by means of a thread which passed round the back of the capillary tube and slightly compressed a small india-rubber tube which acted as a spring to keep it taut as shown. On placing the apparatus on one scale of a chemical balance in a glass case, in which there was also a basin containing chloride of calcium, and balancing it with weights in the other scale, it was found that when both scales were left free to move, one rose and the other fell so rapidly and continuously that their movement was clearly visible to the unaided eye.

Observed during a period of 491 minutes, it was found that the total weight of water evaporated in that time amounted to 1·1958 gm., or at the rate of 2·43 mgm. per minute. The aperture of the capillary tube was elliptical. Its area in cross-section, ascertained by calibration with a thread of mercury 93·2 mm. in length at 20° C. and weighing 3·21 mgm., was 0·02542 mm². It was thus equal to that of a circle 0·18 mm. in diameter, and the velocity of flow of water in the aperture was at the rate of 95·5 mm. per minute.

The Ballistic Theory of Light and the Michelson-Morley Experiment.

IN a note regarding my theory of variable stars, published in NATURE of October 11, p. 550, it is suggested that some difficulties would probably arise on the ground of the Michelson-Morley experiment. As the point is a very important one, I should be glad if space can be given me to make it clear.

The ballistic principle, on which my theory is entirely based, requires that light emitted from a source movable relatively to the observer shall exhibit a velocity compounded of the common velocity *c* and of that of the source. As in the Michelson-Morley experiment the source is at rest in respect to the observer, the ballistic principle requires that light travels with the same velocity *c* in all directions. Hence no displacement of the interference fringes may appear in revolving the whole apparatus. The negative result of Michelson-Morley experiment evidently agrees with the ballistic theory. The same

agreement must hold, in all the experiments directed to detect the total motion, for the ballistic principle has been just introduced from Ritz for the purpose of extending the mechanical principle of relativity to all physical phenomena. This means that the ballistic theory is a *relativistic* one, like that of Einstein, with the two advantages of preserving classical mechanics and of explaining variable stars.

For the sake of completeness, it must be remembered that only in one event would the Michelson-Morley experiment trouble the ballistic theory, that is, only if in repeating the experiment with extra-terrestrial light the result were also negative. Of course, an astronomical light source is not dragged by the earth; light speed, therefore, on the ballistic theory should appear to a terrestrial observer different towards and normal to the motion. Thus, an effect should be expected. As a matter of fact, this experiment proposed by myself in 1912 (*Nuovo Cim.* vol. 3, p. 345, 1912; *Phys. Zeit.* vol. 13, p. 1129, 1912), and recently attempted (R. Tomaschek, *Ann. d. Phys.* 73, p. 105, 1924), cannot give a decisive result, for many difficulties increase when the light falls on a movable mirror, as I have already pointed out (*Ann. d. Phys.*, 75, p. 195, 1924).

In conclusion, ballistic theories are very promising, because they enable us to explain all the phenomena of classical optics and electromagnetism, including the deflexion of light rays near the sun, and they are also fruitful in explaining variable stars, while they finally reconcile both the undulatory and the quantum theories required by recent discoveries.

The Rare Gases of the Atmosphere.

One of the unsolved questions of geophysics is whether the earth's atmosphere is mainly primitive, or whether its constituents have for the most part been evolved from the interior of the earth since solidification. Dr. Aston's letter (Nature, Nov. 29, p. 786) may help to answer this question. The tendency of a gravitating planet to collect heavier molecules to itself, and in certain circumstances to lose the lighter ones, would not by itself account for the rarity of the inert gases. Xenon and krypton have the highest molecular weights of all the atmospheric gases, and would therefore be the most abundant if this were the sole explanation. Possibly the ability of other elements to form stable solid and liquid compounds has co-operated. If so, we may contemplate a heated primitive earth surrounded by a tenuous atmosphere consisting largely of the rare gases as at present represented, with the possible exception of helium. The greater part of the atmosphere, the water, and perhaps the helium, would have been emitted from the interior in the course of the earth's development.

I am much indebted to the reviewer for his careful and kind notice, in Nature of November 22, of my book "The Earth." He has, however, misunderstood me in regarding as a lower limit my estimate of 0·14 astronomical unit as the radius of the primitive sun, at the time of the tidal encounter. It is an upper limit, based on the fact that the sun would have been too cold to be gaseous if its size were any greater. I doubt whether any serious change will be necessitated by the sudden death of the giant and dwarf theory while my book was in the press, but cannot as yet be sure.

Harold Jeffreys.

The Temperature of Mars.

In a recent paper (Pub. Ast. Soc. of the Pacific), Nicholson and Pettit calculate the temperature of the planet Mars, based on their radiation measures made at Mount Wilson. Most confidence is placed on measures made in the region 8 to 14μ, by the use of filter screens, and an emissivity of unity is assumed for all wave-lengths. However, Mars, being probably composed of material not unlike the earth, would radiate more like sand or quartz than like a black body, and it can be calculated from curves given by Wood ("Physical Optics") and data given by Rosenthal (*Wied. Ann.* 68, p. 783), that the average ratio of the emissivity of quartz to that of a black body in the region 8 to 14μ, is 0·819. The values of the emissivity of quartz given are far below that of a black body between 8 and 10μ; they are nearly the same from 10 to 14μ; the average ratio is taken.

It is believed that temperature calculations using this value for the emissivity, and the fourth power radiation law, will be more correct than when an emissivity of unity is assumed. For a given amount of received radiation, the temperature of the radiating body will be higher for a lower emissivity. Accordingly, the temperatures T given by Nicholson and Pettit have been recalculated by applying the method separately to each value of T.

$$\frac{T^4}{T_e^4} = 0{\cdot}819.$$

Low-Voltage Arc Spectra of Copper.

In my letter which appeared in Nature of October 4, p. 501, I reported work I had carried out on the low-voltage arc in copper vapour. I have since then succeeded in obtaining the line absorption of normal copper vapour. The lines which are certainly absorbed, and which, therefore, should be 1*s* combinations, are:

3247·55	2244·24
3273·97	2225·67
2492·14	2165·06
2441·63	

With slight uncertainty there are also the lines:

2181·68
2024·33

In addition, I find from combinations that 2178·91 should also be absorbed, but this is not sufficiently resolved from 2179·39 by the small spectrograph used.

By subtraction from the term 1*s*, the above lines give energy-levels which are all confirmed by combinations with other known terms of the copper arc spectrum. From the arc lines previously reported I have also calculated a number of other terms.

A paper is being written incorporating all these results.

The Origin of Land Vertebrates.[1]

By Prof. E. S. GOODRICH, F.R.S.

WE are all agreed that the four-footed terrestrial vertebrates or Tetrapoda have arisen from some fish-like aquatic ancestor. Two chief changes must have occurred in the passage from water to land—one connected with respiration, the other with locomotion. Moreover, the land animal must have acquired a resistent skin. The fish breathes oxygen dissolved in water, which it takes in by its mouth and expels through its gill-slits, the gills on its gill-arches being organs of respiration.

In the tetrapod, the respiratory organ is a ventral bilobed diverticulum of the pharynx; air is taken in at the external nostrils, passes by the internal nostrils into the buccal cavity, and is thence forced or sucked through the median ventral glottis into the trachea and so to the distensible lungs.

The fish, also, swims by undulations of its body and tail and with the help of paired fins, stiff outstanding folds of the body-wall, each with an internal skeleton movably articulated at its base to the supporting limb-girdle. The walking limbs of the tetrapod, on the other hand, consist of paired pectoral and pelvic projecting limbs built on essentially the same plan, and each subdivided by movable articulations into three regions, the outermost bearing typically five digits. Hence it is called the pentadactyle limb.

The problem before us is, then, to explain how the walking tetrapod evolved from the swimming fish without any sudden alteration of the structure and function of its parts, by a series of gradual steps each of advantage in the struggle for existence.

Before considering the possible claims of any known fish to be considered as ancestral to the land vertebrates, we must first attempt to determine, without going into detail, what must have been the fundamental structure of the common ancestor of all the Tetrapoda. Since the Amphibia still lay their eggs in water and pass through a larval stage provided with gills, it is agreed that they represent the most primitive group of tetrapods living at the present day. The problem is thus narrowed to that of the origin of the class Amphibia. But all the modern forms of the class are highly specialised remnants of a much more ancient and primitive group known as the Stegocephalia (or Labyrinthodontia), which flourished in Carboniferous and Permian times—many of them far larger and more formidable animals than their degenerate modern descendants.

Briefly, we may conclude from a study of extinct and living Amphibia that the primitive ancestral tetrapod had the following chief characters in addition to the lungs and pentadactyle limb already mentioned. It was a heavily built animal, shaped somewhat like a salamander or newt, with a large head, a complete covering of bony plates and scales underlying a soft skin protected by a renewable outer cornified layer and provided with abundant glands to keep it moist when out of the water. The roofing of the skull was pierced by two orbits, two external nostrils, and a median pineal foramen. Internal nostrils opened on the palate. The Eustachian tubes led to a tympanic cavity closed by a tympanic membrane behind the quadrate. A columella auris extended between this membrane and the auditory capsule. Probably the lateral line system of sense organs, present in all fish and in the aquatic larvæ of Amphibia, persisted even in the adult. The brain had well-defined paired cerebral hemispheres. The heart was asymmetrically twisted and the atrium subdivided into left arterial and right venous auricles. The lung received venous blood from the sixth aortic arch and returned it aerated to the heart by pulmonary veins. A vena cava inferior made a short cut from the kidneys to the sinus venosus. The rectum and urino-genital ducts opened into a common cloaca.

Now we may ask from what known kind of fish could such a primitive tetrapod have evolved? What group of the Pisces is sufficiently advanced and at the same time sufficiently primitive to give rise to such a form?

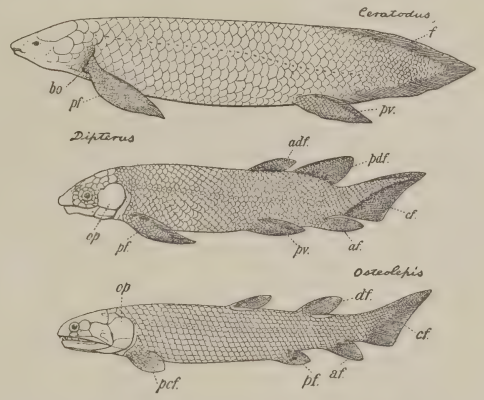

FIG. 1.—*Ceratodus forsteri*, the lung-fish of Australia; *Dipterus valenciennesii*, a Devonian dipnoan (after Traquair); *Osteolepis macrolepidotus*, a Devonian teleostome (after Traquair). From "A Treatise on Zoology," Part IX., by kind permission of Messrs. A. and C. Black.

We divide the Pisces into Chondrichthyes (sharks and rays), with a purely cartilaginous skeleton, and Osteichthyes, in which bone is present. Clearly the Chondrichthyes, with neither true bone nor true scales and with no form of air-bladder or lung, are not eligible. The second group, the Osteichthyes, contains the Dipnoi and the Teleostomi. We shall see that of these the Dipnoi alone display a considerable assemblage of characters which the ancestor of the Tetrapoda must have possessed.

The teleostomes include Polypterus and the Actinopterygii (Acipenser, Amia, Lepidosteus, and the Teleostei and many fossil forms). Of these the Teleostei, which appear only in the Jurassic strata, may be dismissed at once as far too specialised and modern—for it is obvious that the common ancestor of the tetrapods must have diverged from the piscine stem in Carboniferous if not in Devonian times. But even the lower living Actinopterygii show specialisations in the skeleton, brain, and viscera which prove that they all belong to side branches not in the direct line of ancestry.

In the Devonian strata, however, are found certain very primitive teleostomes, such as Osteolepis, which much more closely resemble what we believe to have been the ancestral form.

[1] Substance of a paper opening a discussion in Section D (Zoology) of the British Association at Toronto on August 13.

Indeed, as we pass downwards, we find a gradual convergence in structure between Teleostomi and Dipnoi, and between these and the Stegocephalia, which seems unmistakably to point to a common undifferentiated form from which all three could have evolved. It is just this sort of convergence as we pass to earlier and earlier fossils which makes the study of palæontology so fascinating—affording evidence not only that evolution has taken place, but also enabling us to trace out the course it has actually followed.

Following, then, the teleostomes down into the Devonian, we find that the osteolepids acquire a complete covering of thick scales of the peculiar structure I have named cosmoid, a complete set of roofing bones to the skull which may be compared almost bone for bone with those of the Stegocephalia (a comparison further borne out by the very similar disposition of the lateral line canals and the pineal foramen). Not only were there ventral external nostrils but also internal nostrils on the palate, as Prof. Watson has shown. Both the pectoral and the pelvic fins had outstanding scale-covered lobes.

Allied to Osteolepis, but, it would seem, somewhat off the main line of descent, are the Rhizodontidæ, represented, for example, by Eusthenopteron from the Upper Devonian of Canada and so well described by Whiteaves and Bryant. Primitive as they are, even these Devonian teleostomes are probably already too specialised in their jaw apparatus, large opercular bones, and fin skeleton to be the actual ancestors of the Tetrapoda.

There remains to be considered the very isolated fish Polypterus, surviving at the present day, with a closely allied genus, only in the rivers of tropical Africa. It has a strong superficial resemblance to the osteolepids and was long ago placed with them by Huxley in the group Crossopterygii.

Pollard and others since, relying chiefly on similarities in the roofing bones of the skull, have claimed that Polypterus is, of all living fish, that most closely allied to the tetrapods. The resemblance is, I think, to a great extent deceptive, and only such as might be expected in any fairly primitive fish. It is true that it has a ventral lung-like air bladder supplied from the sixth aortic arch. Nevertheless the structure of its scales, the jaw apparatus, the position of its double nostrils on the outer surface of the snout, the absence of a cloaca, the skeleton of the pelvic fin and girdle, and its specialised brain show that Polypterus is well on the actinopterygian line of specialisation, as I endeavoured to show in a paper on the subject before the British Association in 1907. Indeed there is some reason to believe that it may be the living representative of the ancient group of Palanoniscidæ.

Finally we come to the Dipnoi, that ancient branch of the Osteichthyes dating from Devonian times, but still surviving to-day in isolated remnants, of which the Australian lung-fish Ceratodus is the most primitive genus. Although the modern forms have a highly specialised dentition and have lost many of the dermal roofing-bones of the skull and marginal bones of the jaws, yet they retain several important characters indicating affinity with the Tetrapoda. They have internal as well as external nostrils, and a lung sac opening ventrally, receiving venous blood from the sixth aortic arch and returning aerated blood directly to the heart. The heart itself is remarkably amphibian in the structure of the truncus arteriosus, in the tendency of the valves of the conus to fuse to a spiral longitudinal septum; and even the atrium is beginning to become subdivided, so that the venous and arterial blood-streams pass separately to the right and left sides of the ventricle. The vena cava inferior and the anterior abdominal vein are well established. A cloaca is present, and the urino-genital organs conform to the amphibian plan, as do also the eggs and the larval forms. But more important still is the structure of the brain, which possesses distinct paired cerebral hemispheres. Even the skin resembles that of the Amphibia, being provided with abundant multicellular glands. All these resemblances, both conservative and progressive, can scarcely be due to convergence.

Two important points remain to be mentioned. In all the primitive tetrapods, the hinder region of the palato-quadrate bar (the upper division of the mandibular arch) is not only firmly attached to the skull by basal and otic processes, but also bears an ascending process separating the profundus from the maxillary branch of the trigeminal nerve. Among all the fishes, the Dipnoi alone are known to show this typical disposition.

The second point is that they alone among known fishes, with the possible exception of the more primitive osteolepids, have pectoral and pelvic fins of the same structure—thus sufficiently alike to have given rise to paired walking limbs. In other fishes the pelvic fins are too much reduced or specialised, too unlike the pectorals, to have developed into the tetrapod hind limb. The early Devonian dipnoan Dipterus approaches so closely to the osteolepids (in the structure of the skull, scales, fins, etc.), that we may be sure these forms cannot have moved very far from the common starting-point.

We may conclude that the earliest Osteichthyes diverged into teleostome and dipnoan branches and that the tetrapods arose from the base of the latter branch before the Dipnoi had acquired their characteristic specialisation in palate and dentition. The Devonian Osteolepidæ and Dipnoi seem to have been fresh-water forms, and it is probable that the transition from aquatic to terrestrial life took place in streams and pools, whence access to land was easy.

What exactly were the transitional steps from fin to walking limb we do not yet know. The fin skeleton of the osteolepids is scarcely known, and that of the rhizodonts is probably already too specialised. The living Dipnoi, on the other hand, help us to understand how aerial was substituted for aquatic respiration. For, while retaining gills and open gill-slits, they have become adapted to survival in rivers liable to be dried up or become foul in dry weather by acquiring a nasal passage from external to internal nostril (by closure of the nasal groove) and a lung for breathing air taken in at the surface. The lung had no sudden origin; but, as suggested by A. Goette and Spengel, was probably derived from a posterior pair of gill pouches which failed to open to the exterior, retained an ample blood-supply, and joined together ventrally. To this day the lung first appears in tetrapods as a pair of diverticula of the pharynx.

Thus without break or sudden violent change of habit or structure could an aquatic ancestor have evolved into an animal living on dry land.

The Optical Planetarium at Munich.

MECHANICAL devices intended to represent the motions of the planets date back to a very remote period and are said to have been constructed by the Chinese some 2000 years before the Christian era. It is certain that Archimedes and Posidonius constructed some such apparatus. Machines representing the Ptolemaic system were designed at different epochs up to the time of Copernicus.

In the latter part of the seventeenth century, machines were made by Roemer and Huyghens in conformity with the Copernican plan of the solar system, and various instruments have been devised at intervals up to the present day. It is interesting to note that Roemer presented one of his construction to Flamsteed, the first Astronomer-Royal. These machines all represent the motions of the planets by purely mechanical means, the planets being represented by balls and made to move in their orbits by systems of gearing. As a rule, a system of vertical concentric tubes of different lengths is employed, the innermost being the longest. To the upper end of each tube a radius vector is attached which revolves once for each revolution of the tube, and the lower ends of the tubes form the arbors of toothed wheels which are geared up to a vertical axial. Through this, axial motion is imparted to the whole machine. The radius vector attached to the top of each tube connects the tube with the ball representing the planet, and consists of two parts of different length. The longer is made to revolve round the tube, as has just been described, and the shorter, which carries the planetary ball at its extremity, is made to revolve round the extremity of the longer arm with the same angular velocity as the latter, but in the opposite direction. In this way true elliptic motion is produced, the ratio of the lengths of the two arms determining the eccentricity. The motion of the short arm is often produced by means of a pulley fixed to the planetary tube and connected by an endless cord with another pulley which is situated at the extremity of the longer arm and to which the shorter arm is attached.

It will be noticed that a person following the motions of these mechanical devices is in the position of an observer outside the solar system. Recently a new type of planetarium has been erected at Munich, and it seems to possess some striking advantages over the older and more cumbersome models. In the first place, the mechanical apparatus is compact, and the *images* of the planets are projected *optically* on the surface of a large hemispherical dome at the centre of which is situated the projecting mechanism. Images of fixed stars are also projected on the dome, and an onlooker at the centre of the dome sees the motions represented on a short time-scale as they actually appear to a terrestrial observer. A general idea of the planetarium will be obtained from Fig. 1. The dome is 33 feet in diameter.

Images of the 4500 fixed stars of the first to the sixth magnitude are projected on the dome by a straightforward method. Thirty-one projection bodies are mounted upon a spherical shell of gun-metal with a lamp of 200 candle-power at its centre, and are so divided up that thirty-one lantern slides derived from star-maps form a continuous picture. This device will readily be comprehended by a glance at the top portion of Fig. 2, which is a photographic reproduction of the entire projection apparatus. The stars are represented by means of discs of varying diameters, and the Milky Way is projected by means of a number of small lantern attachments giving nebulous images. The whole of this part of the apparatus is mounted upon an axis corresponding to the earth's polar axis, so that the projected images may move in such a way as to imitate the diurnal motion.

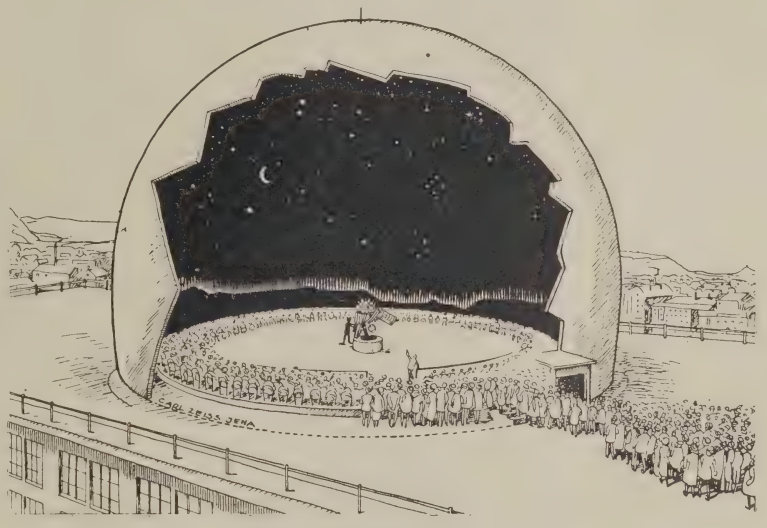

FIG. 1.—Sketch illustrating the planetarium in use.

The projection of planetary motions on the dome is necessarily a rather more complicated affair. The motions of five planets are represented, namely, Mercury, Venus, Mars, Jupiter, and Saturn. Uranus and Neptune are not represented, as they are purely telescopic objects. The motion of each planet is projected by a separate projector, and the principle of the projectors is briefly as follows. By means of a straightforward mechanical device two small steel balls representing the planet and earth are made to revolve round a central point representing the sun, and these balls are connected by a trellis linkage capable of adapting itself to changing distances. A small projection apparatus is attached to the end of this linkage, and consequently the motion of the projected planetary image on the dome represents the motion of the planet *as seen from the earth*. The planes of the paths of the planetary balls in these projectors are inclined at the correct angles to the planes in which the balls representing the earth move, these latter planes being all parallel to each other and inclined at the correct angle to the polar axis of the fixed star projector. The inclinations of the orbits of the planets and the obliquity of the ecliptic are thus taken into account. The orbits of the balls

representing the planets in the projectors are circular, but a crank mechanism takes into account the velocity changes associated with the eccentricity of the orbit. Briefly, the crank mechanism compels the planetary ball to describe a circular path about an eccentric point representing the sun. There is still a residual error left in the vectorial angle which in the most unfavourable case (Mercury when nearest to the earth) leads to an error of 6° in the position of the projected image. In the case of Mars, which comes next to Mercury in eccentricity, the residual errors amount to only $\frac{1}{5}$ those obtaining in the case of Mercury.

In the case of the sun projector, the trellis work to which the projection apparatus is attached simply joins the ball representing the earth to a fixed central pin representing the sun. The moon necessarily presents various complications arising from the comparatively rapid changes in the lunar orbit. The earth is represented by a fixed central pin, and the moon by a ball rotating about another central pin as in the case of the planets. This last central pin is set at an angle to the plane of the ecliptic, thus taking into account the inclination of the moon's orbit, and furthermore is made to rotate about a line perpendicular to the ecliptic, so as to represent the progression of the nodes. No attempt is made to represent the eccentricity of the lunar orbit, as it would have been of no avail unless some mechanism was introduced in order to represent the motion of the apses. This would have led to great difficulties in the gearing mechanism, and the lunar orbit is accordingly represented as circular. This leads to a maximum positional error of about 6°. The phases of the moon are imitated by mounting a small revolving stop behind the circular diaphragm which furnishes the projected image. Actually such a stop would represent the phases correctly through one complete lunation, but would furnish their mirror images during the next. Accordingly the phase projecting attachment has two alternately operating projection heads. The phases of the planets are not reproduced, since they are not naked-eye phenomena.

The projectors for the sun, moon, and planets will be seen on the left-hand side of Fig. 2. The precession of the equinoxes is also allowed for in the mechanism. The whole apparatus is driven by an electric motor, and by means of a change gear a sidereal day can be condensed into $4\frac{1}{2}$ minutes, 2 minutes, or 50 seconds. In order to exhibit the motions of the sun, moon, and planets more rapidly, a device is attached by means of which the polar axis can be disengaged and the motions of the solar system run at a rapid rate (exhibiting the annual changes in $4\frac{1}{2}$ minutes, 50 seconds, or 7 seconds) against the fixed star sky, the latter being unaffected by diurnal motion and showing only the slow precessional change.

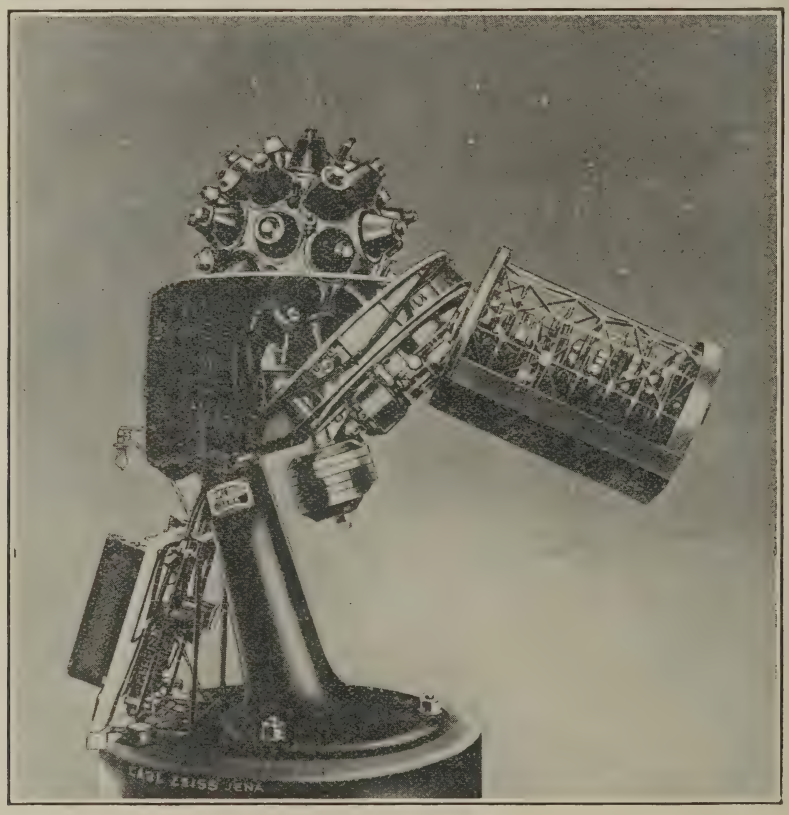

FIG. 2.—Projection apparatus.

The foregoing is a brief description of an instrument which probably represents the most successful attempt yet made to picture the heavenly motions. Its designer apparently claims that it is valuable as an astronomical work of precision. Some astronomers might possibly not feel inclined to lend unqualified assent to this claim, but few will deny the educational value of the apparatus, and there can scarcely be any doubt that the public at Munich and elsewhere will show their appreciation of the brilliant and successful efforts of all who have been concerned in the design and erection of this beautiful device.

Radio Communications.[1]

By Senatore G. MARCONI.

I HAVE always attached considerable importance to the problem of a practical directive system of radio communication. During my earliest experiments carried out in England more than twenty-eight years ago, I was able to show the transmission and reception of intelligible signals over a distance of 1¾ miles by means of an elementary beam system employing very short waves and reflectors, whilst, curiously enough, by means of the antenna or elevated wire system, utilising much longer waves, I could only at that time get results over a distance of half a mile.

The progress made with the non-directional long wave system was, however, so rapid and the results so immediately applicable to practical purposes, that it very soon became, and still remains, what might be called the standard system. It is regrettable that the study of short waves was neglected for a long period of years, for these waves, which, so far, are the only ones that can be confined to narrow beams, are also capable of being employed to give practical results unobtainable by the lower frequency system, which, up to now, has held the field for long-distance communication.

When during the War in 1916 I took up the systematic study of short waves, considerable doubt existed in my mind, and in that of other workers, as to whether the range of these waves might not prove to be too small for practical and useful purposes, particularly during daytime, if they might not be altogether too untrustworthy, and also as to whether large stretches of land, and particularly mountains, would not present absolute obstacles to their transmission over long distances.

In 1920 experiments were carried out by Capt. H. J. Round with duplex telephony on a 100-metre wave between Chelmsford and Southend, and the experiments were so successful that early in 1921 two stations which had been erected at Southwold and Zandvoord on the Dutch coast were put into commission experimentally, Southwold station utilising about 1 kilowatt to the aerial. Experiments were carried out, transmitting from these two stations to Norway in August 1921, and at Christiansund day and night telephony was easily received from both stations. At Christiania, about 700 English miles distant, very loud and constant signals were received during the hours of darkness and in the daytime on certain days, apparently when the barometer was low.

During these experiments the curious night distortion of telephone signals was discovered, particularly when transmission was overland, the major cause of which has more recently been discovered by Capt. Round in his work on broadcasting. Later, the results of these tests were merged into the general short-wave beam experiments.

During the tests carried out on the steam yacht *Elettra* in the spring and summer of 1923, I was able to discover that the short wave I was then using could not only cover great distances by day, and much greater distances by night, but that it was also quite trustworthy and that, moreover, large parts of continents and ranges of mountains did not materially reduce their working distance.

A series of tests was for the first time carried out with short waves over what might be termed world-wide distances during the winter, spring, and summer of this year, between Poldhu in Cornwall and receiving stations situated on ships at sea and also at such places as Montreal, New York, Rio de Janeiro, Buenos Ayres, and Sydney (New South Wales, Australia). All these tests proved to be successful, including the first telephonic communication with Australia ever realised, although the amount of power utilised at the sending station never exceeded 20 kilowatts. Very strong signals were obtained at all these places during the hours when darkness extended over the whole distance separating each of them from Poldhu, and weaker signals for a few hours when the sun was about the horizon at either end, the intensity of the signals varying inversely in proportion to the mean altitude of the sun when above the horizon. Although the signals were received with great strength at New York, Rio, and Buenos Ayres during the time when darkness spread over the whole or at least the major part of the great circle track separating these places from Poldhu, no signals at all were ever received, during these tests, when the same track or part of space was all, or substantially all, illuminated by the light of the sun.

While this limitation of the period of working to practically the hours of darkness constituted an undoubted disadvantage, still the economical advantages, together with the trustworthiness and possibility of working this system at far greater speeds than would have been feasible with the well-known high-powered long-wave installations, went far to convince me that the short-wave beam system would be capable of transmitting a far greater number of words per 24 hours between England and far-distant countries, such as Australia, than would be possible by the comparatively powerful, cumbersome, and expensive stations actually in use, or which were planned to be used, for Imperial commercial communications. It is a satisfaction to me to be able to state that the stations intended for this purpose in England and others to be installed in the principal Dominions and far-distant countries will all be on the beam system.

Commencing in August of this year, a further series of investigations was carried out between Poldhu and the yacht *Elettra*, the object being to endeavour, if possible, to find means of overcoming the limitation of working hours brought about by daylight, and also to test whether the effect of the reflectors would give the expected increase of signal strength over long distances. The yacht proceeded to Spain, then to Madeira, and afterwards to Italy. From Naples we sailed for Beyruth in Syria, touching at Messina and Crete, returning to Naples via Athens.

At Madeira it was ascertained that a reflector at the transmitting station increased the strength of the received signals in accordance with our calculations, but that, notwithstanding this increase of strength, when using a 92-metre wave, the daylight range was

[1] From the inaugural address to the Royal Society of Arts delivered on December 11.

only very slightly augmented. Comparative tests were carefully carried out with waves of 92, 60, 47, and 32 metres also at other places in the Atlantic and Mediterranean.

These tests enabled us to discover that the daylight range of practical communication over long distances increased very rapidly as the wave-length was reduced, the 32-metre wave being regularly received all day at Beyruth, whilst the 92-metre wave failed to reveal itself for many hours each day even at Madeira, notwithstanding the fact that the distance between Poldhu and Madeira is 1100 miles, entirely over sea, whilst that between Poldhu and Beyruth is 2100 miles, practically all over mountainous land. Our observations went to confirm the fact that for waves between 100 metres and 32 metres the daylight absorption decreased very rapidly with the shortening of wave-length.

These results were so interesting and satisfactory that I immediately decided to try further tests over much greater distances. In October of this year, transmission experiments were carried out on a 32-metre wave from Poldhu to specially installed receivers at Montreal, New York, Rio, Buenos Ayres, and Sydney (Australia). Although the available power utilised at Poldhu was only 12 kilowatts, it was at once found possible to transmit signals and messages to New York, Rio, and Buenos Ayres when the whole of the great circle track separating these places from Poldhu was exposed to daylight. During a complete day transmission at fixed intervals carried out last October with Sydney, New South Wales, that station received the Poldhu signals for 23½ hours out of the 24, and a 48-hour test which was only completed on December 10 fully confirmed the result.

The tests from England to places situated south of the equator, such as Sydney, Buenos Ayres, Rio de Janeiro, and Cape Town, are particularly interesting for the reason that the waves have always in these cases to traverse what may be called a summer zone. They are therefore subjected to an averaging effect of conditions, which can never possibly exist when the transmissions take place only between stations situated in the northern or southern hemispheres. During November some successful receiving tests were carried out in England, from a low power transmitting station in Australia utilising waves of 87 metres. During the present month of December, trials have been continued with Canada, the United States, Brazil, the Argentine, and Australia, and also, for the first time, with Bombay and Karachi in India and Cape Town in South Africa. The power utilised at the Poldhu station during all these tests was 15 kilowatts.

The results have fully confirmed my expectations in regard to the behaviour of the various wave-lengths over such great distances, and I have no doubt that the information gained will render possible the installation of comparatively low power stations capable of establishing and maintaining commercial services by day and by night between England and the most distant parts of the globe.

The low cost of this system both in capital and running expenses, compared with that of the existing type of stations, must prove to be very great, and should bring about the possibility of a reduction in telegraph rates for all long-distance communications, besides making direct communication with some of the smaller outposts of the Empire commercially remunerative. Already the size and power of some of the most modern long-wave stations was becoming a serious question from a financial point of view. The newly equipped station at Buenos Ayres, for example, which was designed primarily for communicating with Europe over a distance of about 6000 miles, employs 800 kilowatts and an aerial supported by ten towers, each 680 feet high. This station usually works on wave-lengths of about 12,000 and 16,000 metres. Another example is the British Post Office station which is being erected near Rugby, which, when completed, will employ 1000 kilowatts and an aerial supported by 16 towers, each 820 feet high, while the station being erected in the Union of South Africa was designed on a similar gigantic scale.

I am now firmly convinced that the beam stations employing only a small fraction of this power and much lower and fewer masts will be able to communicate at practically any time with any part of the Empire, and I cannot refrain from expressing my strong personal opinion that these powerful long-wave stations will soon be found to be uneconomical and comparatively inefficient in so far as long-distance commercial communications are concerned. Although we have, or believe we have, all the necessary data for the generation, radiation, and reception of electrical waves, as at present utilised for long-distance communications, we are still far from possessing anything approaching an exact knowledge of the conditions governing the propagation of these waves through space. These results indicate quite definitely that the well-known Austin formula is inapplicable to these waves. Another formula will have to be devised, based on the results of further investigations.

Reflectors of practical and economical dimensions are only efficiently applicable when short waves are used, and, although very long distances have been covered by these waves without the use of directional devices, I am convinced that these will be found to be essential for ensuring the carrying out of commercial high speed services. The disadvantageous effect called "fading" is sometimes a source of serious trouble when receiving signals transmitted by means of short waves, although much less serious than when waves of several hundred metres in length are employed. According to our experience, the use of reflectors diminishes fading, and also tends to overcome its effects by enormously increasing the strength and therefore the margin of readability of the received signals.

Increasingly large and expensive reflectors could, of course, be used with longer waves than 100 metres, but the results of all recent tests seem to indicate that the shorter waves present the greatest advantages, one of the most important being that their reception is very much less liable to interference by the effects of atmospheric electrical disturbances, or "X's."

If these waves are destined to carry a considerable part of the most important long-distance telegraphic traffic of the world, it may well be necessary in the near future, by international legislation, to regulate their use and safeguard them from preventable interference.

The Leeds University Celebrations.

DISTINGUISHED representatives of universities throughout the British Empire and of learned societies and professional bodies gathered together at Leeds during last week to join with local bodies in congratulating the University of Leeds on the attainment of its majority—an event which coincides with the jubilee of the parent institution, the Yorkshire College of Science. In the course of a series of important ceremonies spread over the whole week, the outstanding events were the sermon preached by the Archbishop of York in the Parish Church, Lord Balfour's great speech at the University dinner, the eloquent words with which Sir Michael Sadler reviewed the University's history, the addresses delivered by delegates at the official reception, and Sir Berkeley Moynihan's brilliant survey of the record of surgery in Leeds.

The wide and influential response to the invitation to participate in these celebrations is a tribute to the success which has attended the efforts of this young University. But it is not in this fact that the real significance of the gathering is to be found. Rather is it to be taken, first, as a demonstration of that fellowship within the world of learning which, important in its direct help to the advance of knowledge, may also exert a profound influence in producing a better understanding between the peoples of different countries; and, second, as evidence of the general recognition of the fact that of all the progress which has been made in education during the last fifty years, nothing has been so remarkable as the growth of the modern universities. Of this growth, the University of Leeds provides a good example, and it is perhaps to this more than anything that is due the representative character of last week's brilliant assembly.

The Yorkshire College of Science opened its doors on October 26, 1874, as the result of the efforts of a Yorkshire Board of Education the purpose of which was to bring about the development of scientific instruction in the county. The ground had been prepared for this new venture by the work of the Mechanics' Institutes, the formation of science classes, and the growing opinion in favour of scientific training as an aid to industry. Sir Michael Sadler puts forward the view that the aims of the promoters of the College were not so narrowly utilitarian as has generally been supposed, believing that they had in their minds a larger view of the purposes of the College than they thought it necessary to disclose. Their arguments were mainly based, however, on the industrial needs of the country, and they defined the objects of the College as being "to supply instruction in those sciences which are applicable to the Manufactures, Engineering, Mining, and Agriculture, of the County of York, also in such arts and languages as are cognate to the foregoing purpose." But, even if their aim was wholly utilitarian, it seems unnecessary to seek excuses for them. They were without question pioneers whose ideas were well in advance of general opinion, and their efforts achieved a notable development in higher education. Some there were who felt at the time of the establishment of the College that it was being confined within unduly narrow limits. Amongst these was Dr. Lyon Playfair, than whom the College could have had no more competent adviser. Lord Frederick Cavendish, the president of the College, was also emphatic in urging the avoidance of a one-sided concern. It is clear, therefore, that, whatever may have been the opinion of the general body of promoters, there was influential and expert support for the opinion expressed in the columns of NATURE on October 14, 1875: "If the County is as earnest in furthering its welfare as we believe it to be, the institution ought not to remain long on its present limited basis."

The widening of the curriculum of the College came about very quickly, and the cause of it was not primarily the pressure of outside opinion but the demand from within, coming both from the professors who were appointed to teach science and from the students who were in attendance for the purpose of studying science. Both staff and students found the need for literary studies if their work was to secure its best results. Some credit for the development must be given also to the external examinations of the University of London, which demanded a wider range of knowledge than could be gained within the early curriculum of the College. It was the work of the Cambridge University Extension Lectures scheme which made possible, only three years after the beginning of the College, the addition of literary and historical subjects to its courses of study. The College took over the work of the Extension Committee in 1877 and, in the following year, renamed itself "The Yorkshire College." In 1884 the Yorkshire College joined forces with the Leeds School of Medicine (which had been at work since 1831), and three years later attained university status by admission into the Victoria University. In 1904, having unsuccessfully opposed the dissolution of this Federal University, the Yorkshire College secured an independent Charter as "The University of Leeds."

Perhaps the most remarkable thing about the history of the Yorkshire College and the University of Leeds is the fact that from its very beginning until the present day its growth has continued without cessation. In this it has more than kept pace with the development of public opinion in favour of university education and with the realisation of the value of scientific research. Its governing body, constituted on a representative basis, has been able to retain its independence while accepting large sums of money from the State and the Local Authorities, and from other contributing bodies. This position (not maintained without certain struggles) has enabled the University to develop in a way which would scarcely have been possible under restrictions imposed by external authority. The University has attached more importance to staffing than to buildings, and, though it may have suffered in appearance, its policy has been more than justified by its results. Served by men and women of distinction, performing work of high value, and having the advantage and the dignity of self-government, the University has attracted to its governing body men of great business capacity, and its affairs have always been managed with efficiency.

The congratulations which have been showered upon the University of Leeds on the occasion of its jubilee indicate the general satisfaction of sister institutions and the public with the manner in which a College

founded on unambitious lines has grown in the space of fifty years into a University with nearly 2000 students and a staff of 268, constantly widening its range of studies, developing a strong Faculty of Arts while maintaining the distinction of its scientific work, retaining through all this expansion the atmosphere of friendliness in which it justifiably takes pride, and meeting its financial obligations in face of an annual expenditure increased in the space of six years from 70,000*l.* to 173,000*l.*

The University of Leeds is also entitled to congratulation for its present resolve to continue its progress in spite of the severe financial difficulties which stand in the way. It has set itself the great task of providing buildings worthy of its high purpose and of enlarging its endowment for scientific research. The purpose is one which deserves and will no doubt receive general commendation, and our best wish for the University is that its present enterprise will be crowned with a success equal to its past achievements.

Obituary.

Prof. Iaroslav Hlava.

WITHIN recent times the Czechoslovak nation has suffered several losses of eminent professors of its Charles' (Bohemian) University, which have been recorded in NATURE. Prof. Iaroslav Hlava died in Prague in his seventieth year on November 1. Prof. Hlava was the senior of the medical faculty and its eminent, most representative member. He was professor of pathological anatomy and of bacteriology, but he had to establish the chair of that science for our nation, for up to the year 1882 it was represented only by German professors. He began his career as a demonstrator of Prof. Klebs in Prague and then studied under Conheim, Weigert, Wirchow, Recklingshausen, Cornil, Vulpian, and Stricker.

Hlava became in 1884 associate professor, and in 1887 ordinary professor; later he was dean of the faculty, and in 1906 Rector Magnificus of our University. He was a great teacher of pathological anatomy. But he was also a well-known scientific investigator, and the number of his scientific discoveries and publications is too great to be mentioned here in detail. The principal object of his investigations were the infectious diseases, the modern teaching of which celebrated its triumphs at a time when Hlava was a young man. Bacteriology was in our country closely connected with his name. His special study was that of exanthemata, especially of scarlatina and of exanthemic typhoid fever, but this investigation proceeded very slowly, owing to the scarcity of this disease, and was brought to a close only during the War. His other investigations covered histology, epidemiology, and parasitology.

Hlava published most of his papers in the Bohemian language, and established for this purpose a special Collective Journal. To every paper a French résumé was added, and so Hlava's work became known in foreign countries. How it was appreciated there is evident from the great interest by which his numerous papers were received at different scientific congresses, especially French, Russian, Polish, and Jugoslav. A proof of it is given by the fact that he was not only a member of Bohemian learned societies like the Bohemian Academy of Sciences, and president of our Medical Society and of the High Sanitary Council, but also president of the Bohemian national committee at many scientific congresses, and foreign associate of the Academy of Medicine in Paris, member of the military Medical Academy of Petrograd, and a number of other medical societies in various countries. He received three high Serbian decorations. The imposing monument which exists in his wonderfully up-to-date Pathological Institute (called Hlava's Institute) will be a permanent symbol of his scientific significance.

BOHUSLAV BRAUNER.

CAMBRIDGE mourns the death, on December 7, of Richard Irwin Lynch, who for forty years was Curator of the University Botanic Garden. Mr. Lynch was born at St. Germans, Cornwall, in 1850, and went to Kew at the age of seventeen. He rose to the position of senior foreman, which he held until 1879, when he came to Cambridge. Of his many publications, all written in a fresh and charming style, perhaps the best known is his book on Iris. He is also well known by the Cineraria and Gerbera hybrids he raised. The University gave him an honorary degree of M.A. in 1906, and in the same year he received the Victorian Medal for Horticulture from the Royal Horticultural Society. In 1923 he received the Veitch medal inscribed "To R. Irwin Lynch for his work in Horticulture." He was an accurate botanist and an assiduous collector, and few of the present generation know how much Cambridge owes to him. On his retirement in 1919 he went to live at Torquay, a move deeply regretted by his numerous friends in Cambridge, who would have enjoyed his companionship, and been glad of his help and advice about everything to do with gardening.

H. G.-C.

WE regret to announce the following deaths:

Prof. Hugo von Seeliger, professor of astronomy and director of the observatory at Munich, and formerly president of the Bavarian Academy of Sciences, on December 2, aged seventy-five.

Dr. Otto Pufahl, professor of metallurgy in the mining department of the Berlin Technische Hochschule, on November 18, aged seventy.

Dr. Carlo De Stefani, professor of geology and physical geography in the Royal University of Florence, on December 12.

M. Eugène Simon, correspondant of the Paris Academy of Sciences in the section of anatomy and zoology, and author of the "Histoire naturelle des Araignées," on November 17, aged seventy-six.

Dr. Felix Tannhäuser, extra-ordinary professor of mineralogy and geology at the Technische Hochschule and the University of Berlin, on December 2.

Current Topics and Events

IN the Rationalist Press Association Annual for 1925 there is an interesting and suggestive article by Sir Arthur Keith on "Capital as a factor in Evolution." The gist of it is that we see in the biological order a closely similar use of saving for the purpose of higher development to that which we see in the sociological order in the use of capital. Sir Arthur develops the argument in considerable detail both in the case of the fowl, where the yolk-saving habit is carried to a very high point, and also in that group of fishes which lie near the ancestral line of the higher vertebrates, namely, the Selachians (sharks, rays and dog-fish). The argument is a continuation of Francis Balfour's discovery of forty years ago that the key to many of the obscure problems surrounding the development of the higher vertebrates may be found by studying the embryology of the Selachians. This is specially true of the structures which allow the young to draw their nourishment from the womb of the mother. The placenta is the most wonderful of these devices gradually developed. In the case of man it is just in the later intra-uterine period that the new and characteristic features of the brain and body are invented and worked out. We may then fairly continue the argument to the period of dependence prolonged after birth and after childhood. Only capital, that is saving, makes this possible. Knowledge is absorbed and increased owing to the shelter and the leisure provided by capital. This is, of course, only one aspect of the case for capitalism, but for those who care first for the intellectual stability and progress of mankind it is perhaps the most important: it is unfortunately the most easily overlooked by the Communists either of Russia or anywhere else.

AT a meeting of the Institution of Electrical Engineers on December 18, Mr. Donald Murray gave a very interesting forecast of the telegraphy of the future. It is common knowledge that the present system of telegraphy is far from satisfactory. Telegraph lines could be loaded to many times their present capacity without any change being necessary; the delays occur at the sending and receiving ends. Mr. Murray points out that if printing transmitters and receivers were installed in each user's office or home, it would be possible for him by means of automatic exchanges to receive or to send long printed messages over any distance in a few minutes. The method is past the experimental stage. The British Post Office has received and transmitted printed messages over considerable distances for several years. The introduction of automatic telegraph exchanges is merely a question of time. In the new telegraphy any ordinary typist working at from 40 to 80 words a minute could send the message which would be received in full printed form in a few minutes' time, no matter how great the distance between the sender and the receiver. The main obstacle in the path of progress is the price of the teletype machines, but once the demand increased to tens of thousands there is no reason to suppose that the price would be appreciably greater than that of a good typewriter. A probable development would be the broadcasting of printed news by a teletype receiver which could be actuated through the ordinary telephone wire. The use of the teletype printer will shortly take place in the United States, as both the Western Union and the Bell Telephone Co. are offering facilities to business men. The continually extending use of automatic telephones and telegraphs will gradually reduce the number of telephone girls and telegraph operators. Another effect will be to speed up to the utmost limit the rate at which business men work.

IN the account of the experiences of the Mount Everest expedition which appears in the December number of the *Geographical Journal*, Mr. N. E. Odell, who climbed to nearly 27,000 ft., makes some important observations with regard to the use of oxygen at high altitudes. He believes that if a man has been acclimatised at altitudes of say 22,000 or 23,000 ft., he can do without oxygen. Furthermore, he thinks that oxygen used liberally may be regarded as a source of danger by preventing the user from proper acclimatisation, and greatly increasing the chances of his collapse if the apparatus breaks down. The weight of the present apparatus, about 30 lb., combined with its bulk, obviates any advantage to be gained from it. Mr. Odell records the interesting physiological fact that all members of the recent expedition who had served in previous attempts acclimatised quicker than new-comers. He concludes by stating his belief that Mount Everest can be climbed without oxygen, and that if a high climbing party carries it in future, it should only be in small quantities, as an emergency measure, and must be contained in much lighter apparatus. Articles by other members of the expedition give a full account of the attempt on the summit, and are illustrated by a number of beautiful photographic plates.

THREE recent papers on the laws governing population growth were discussed by Dr. T. H. C. Stevenson, of the General Register Office, at a meeting of the Royal Statistical Society held on December 16. Dr. Stevenson stated that the birth-rate for Europe as a whole, which during the nineteenth century, so far as covered by the official records, had not varied very greatly, took a sudden downward plunge with the advent of the 20th, and continued to fall, at an accelerating pace, until the outbreak of war in 1914 spoilt the comparison. Germany was much more affected by this movement than England and Wales, where the birth-rate decline during the fourteen years before the war had been very similar to that of Europe generally. This fact might have contributed towards fixing the date for putting Germany's war machine in motion. If the death-rate had varied without reference to population conditions, and in the opening years of the present century, the birth-rate also, this would make the future course of population all the

more difficult to prognosticate. The very suddenness of the change suggests interference with the laws of Nature, as by increased practice of contraception, rather than a change in the laws of Nature themselves.

THE Natal Museum has issued two series of pictorial post-cards, ten in each series, illustrating the mammals of South Africa. They represent photographs of natural groups set up in the Museum and, as the groups have been mounted in natural attitudes and arranged amidst surroundings representing as closely as possible the special habitat of each species, the cards provide an excellent series of illustrations of the characteristic mammalian fauna of South Africa, mainly antelopes, but including elephant, rhinoceros, zebra, and lion. They are very pleasingly reproduced and of considerable artistic merit, and are, at the same time, an eloquent tribute to the fine work which is being done at the Natal Museum. With each series is issued a leaflet in which a reasoned plea is made for the international protection of the African fauna. The cards, by showing the reader of the pamphlet the beauty of what he is asked to protect, should be very helpful propaganda in enlisting practical support for the cause which Dr. Warren, as indeed all naturalists, has at heart. It is to be hoped that the series of cards will be extended to other groups of animals, for they must prove of great educational value as an aid to the teaching of natural history in the schools of South Africa.

DR. JOHANNES BÜTTIKOFER, director of the Zoological Garden at Rotterdam, has been elected a foreign member of the Zoological Society of London.

THE Foulerton Award of the Geologists' Association will be presented to Mr. A. L. Leach at the annual general meeting to be held next February. Mr. Leach was honorary secretary of the Association for the period 1913–1918.

THE Aerodynamics Experimental Department of the Royal Aircraft Establishments requires a number of test assistants. Applicants must have had technical training to the standard of a degree in natural science or engineering, and be willing and medically fit to fly as observers. Applications, marked A. 43, should be sent to the Superintendent, R.A.E., South Farnborough, Hants.

PROF. C. VERNON BOYS has been awarded the second Duddell Memorial Medal by the Council of the Physical Society of London. According to the terms of the Duddell Memorial Trust, the award is "for the advancement of knowledge by the invention or design of scientific instruments or by the discovery of materials used in their construction." The award to Prof. Boys was by a unanimous decision of the Council.

THE Safety in Mines Research Board requires the services for a year of an investigator to carry out work on the strengths of various structures for the support of underground workings in coal-mines. The possession of a university degree or its equivalent in engineering is a necessity. Forms of application, returnable not later than December 31, can be obtained from the Under-Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, S.W.1.

DR. F. P. STOWELL has been elected as the first Aquarium Research Fellow of the Zoological Society of London. Dr. Stowell is a graduate of the University of Liverpool, where he has been carrying out research in chemistry. The Fellowship, which is tenable for 3 years, is of the value of 350*l.* a year, and has been established for the investigation of the conditions affecting aquatic life in fresh and salt water aquaria. There were twenty candidates for the Fellowship.

APPLICATIONS are invited by the London School of Hygiene and Tropical Medicine (Division of Tropical Medicine and Hygiene) for the post of assistant in helminthology. Candidates must hold a science degree and be qualified in medicine or veterinary medicine. Applications, with particulars of candidates' experience and research, copies of their scientific contributions, and the names of not more than three referees, must be received by, at latest, January 1, by the Secretary of the School, Malet Street, W.C.1.

THE Harrison Memorial Prize selection committee announces that it is unable to make an award of the Harrison Memorial Prize for 1924. According to the terms of the trust deed, the award is in the hands of a committee consisting of the presidents of the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry, and the Pharmaceutical Society, and is given "for the most meritorious and promising original investigations in any branch of pure or applied chemistry" of the previous five years.

THOSE who have contributed to the proposed memorial to the late Dr. and Mrs. Augustus D. Waller will be glad to know that the sum of 2000*l.* has been subscribed towards the memorial at the London (Royal Free Hospital) School of Medicine for Women, and a trust deed has been drawn up embodying the resolutions of the final meeting of the Committee and subscribers held on July 17 last. The money has been handed over to the Council of the Medical School; it is being invested as a capital sum, and the interest will be applied for purposes of scientific research. The sum of about 105*l.* has so far been subscribed for the proposed memorial of a Waller Research Room at St. Mary's Hospital. If the scheme does not materialise in a year, the donors will be consulted as to the use of their money. A complete list of subscribers has now been prepared.

CATALOGUE E issued by Messrs. Flatters and Garnett, Ltd., 309 Oxford Road, Manchester, lists the lantern slides which that firm has available for purchase or hire. It consists of no less than 100 closely printed pages with a few representative

reproductions, and includes a wealth of subjects, mainly of a natural history type. The slides showing various plant associations should be particularly useful. There are numerous slides illustrating technical features of botanical, geological, zoological, and related specimens, while sections of the catalogue are also devoted to astronomy, textile fibres and machinery, and so on. A useful index to the subject matter concludes the pamphlet.

A BIBLIOGRAPHY of meteorological literature prepared by the Royal Meteorological Society with the collaboration of the Meteorological Office, Air Ministry, No. 6, has recently been issued by the Royal Meteorological Society. The bibliography is now published in six-monthly parts; prior to 1921 it formed a part of the Society's Quarterly Journal. The publication is of great value to meteorologists in different parts of the globe, especially as the science of the weather is now making such rapid advances; it helps the inquirer to sort out literature on the branch of work with which he is interested. The divisions deal with the physics of the atmosphere, the upper air, and with more ordinary topics such as temperature, rain, wind, atmospheric electricity, and weather forecasting.

THE Institution of Heating and Ventilating Engineers is offering to assistants in the profession the following premiums: the Lumby, value 10*l.* 10*s.*, the Sirocco, value 10*l.* 10*s.*, and the Grenville, value 5*l.* 5*s.*, each carrying a medal of the institution. The Lumby premium will be for the best paper submitted dealing with, or any subject connected with, heating or hot-water supplies; the Sirocco premium for the best paper submitted dealing with ventilation and the general application of fans; air washing, air conditioning, dust and fume removal, mechanical draught, etc.; and the Grenville premium for the next best paper on any subject included in the above. Each competing essay must be written under a *nom de plume*, with the name and address of the sender in a separate sealed envelope, and be sent to reach the secretary of the Institution, 38 Victoria Street, S.W.1, not later than March 31 next. Further particulars are obtainable from the secretary.

Our Astronomical Column.

BRIGHTNESS OF PLANETS AND STARS. — The *Chaldaean* (vol. vi. No. 21) contains an interesting article by C. Schoch on the brightness of stars and planets at various distances. The most recent values of the planetary albedoes are employed. The earth seen from the moon is of mag. −16·6, but Mars seen from Phobos is −22·5, very little fainter than the sun seen from Jupiter, which is −23·2. The earth from Venus is −6·5, seven times as bright as Venus from the earth.

The brightest planet, seen from another planet, is Venus from Mercury, −7·7 mag., the earth from Venus coming next with −6·5. The moon from Venus is −2·4.

Of satellites seen from their primaries, our moon is very much the brightest, mag. −12·55; the two next brightest are Phobos from Mars −8·0, and Io from Jupiter −7·7. The table emphasises the fact of the great superiority of our moon as a light-giver, compared with the combined light of the satellites of the other planets, even if all could be full together.

The paper also gives the absolute magnitudes of several fixed stars. The three brightest are Deneb (α Cygni) −7·2, Rigel −5·8, Canopus −4·2, but as their parallaxes are very small, there is considerable uncertainty about these values.

THE DISTRIBUTION OF ENERGY IN STELLAR SPECTRA.—An interesting paper by Dr. C. G. Abbot on this subject appears in the *Astrophysical Journal*, vol. 60, p. 87. In place of the bolometer which he used in his earlier investigations of energy distribution, the author has employed a new type of radiometer, specially designed by Dr. E. F. Nichols for this type of work and used with the Mount Wilson 100-inch telescope arranged in the Coudé form. The deflexions were read visually on a phosphorescent scale placed 5 metres from the radiometer mirror. Observations were made in this way at fifteen different wave-lengths in the spectra of nine bright stars, and the results (reduced to normal conditions by comparison with solar observations) are given in diagrammatic form. It is interesting to note the very pronounced double maximum in the case of Rigel, and also the fact that Vega and Sirius (which are both of type Ao) show different energy distributions—the point of maximum, in particular, being very different in these two stars.

A tentative comparison is made of these curves with the theoretical "black-body" curves, and the diameters are computed of perfect radiators which would give emissions equal to those of the stars at the same temperatures. These diameters are found to compare favourably both with interferometer measures of stellar diameters and with Russell's theoretical values.

MECHANICAL ANALYSIS OF PERIODICITIES. — A problem of very frequent occurrence in astronomy is that of determining, from a set of observed values of a character (such as magnitude or radial velocity) which varies with time, the periodic time of variation. A mechanical method of solving the generalised problem has been applied by H. de Miffonis, and is described by him with detailed drawings in the *Astrophysical Journal*, vol. 60, p. 133. The principle underlying this instrument is to choose beforehand a definite length (*e.g.* 2 inches) to represent the required period, and then to alter the time scale of the observations by means of adjustable "time bars" until the period has the chosen length. The observations are represented by black dots on celluloid strips. Other dots are then arranged at intervals of two inches (in the time direction) on either side of the observation dots over the whole range of the instrument, and the time scale is adjusted by means of a hand wheel until these dots all lie as nearly as possible on a smooth curve.

The machine appears to be rather elaborate for its purpose unless a great amount of such work has to be done, but a useful description is added of a graphical method of solving such problems, involving the same principle, which can be used if the number of observations is insufficient to warrant the building of the machine as originally designed.

Research Items.

STONE IMPLEMENTS FROM TEXAS.—In the *Journal de la Société des Américanistes de Paris* (vol. xvi. N. Sér.), Dr. Chas. Peabody describes a number of implements of chipped flint from Kerrville, 120 kilometres north-west of San Antonio. There are in this area a large number of mounds of small dimensions varying from five to fifteen metres in diameter. So far as observed, these were not burial mounds and they usually occur along water-courses, particularly on a tongue of land between two streams. The specimens were obtained entirely from the surface. They include hammer stones; chipped axes with platforms usually covered with the original crust, varying from five to twenty centimetres in length, and very rough; arrow-heads with and without tangs; lance points, ceremonial and other, a few resembling Solutrean *feuilles de laurier*, with an occasional tendency to the sinuous edge and alternate retouching; knives, sometimes with flattened bases and stop-ridges for hafting, showing a striking similarity to Upper Palæolithic knives and scrapers. Among the scrapers, side scrapers are rare, but great ingenuity was shown in forming "snub-nosed" scrapers; while the long scrapers are identical with the *grattoirs carénés* of the Upper Palæolithic. Other forms were drills and spokeshaves. Flints are never found on the mounds, but lying near by. The patina is varied, generally blue or white. As Kerrville lies at the point of contact (at the beginning of historical times) of the Shoshoneans, Athapascans, and Coahuitlans, variety is to be expected, and it may be possible to establish the existence of trade and trade routes. To this the discovery of a piece of hæmatite, which is not known to occur in the neighbourhood, appears to point.

HUMAN MIGRATIONS.—An analysis of human migrations by Dr. Réné le Conte in the current issue of *Scientia* suggests a classification into those which are caused by violence and those which were carried out peaceably. Each class is capable of further subdivision. There are, for example, the armed movements of whole peoples in search of new land to cultivate or new lands for pasture, the latter to be distinguished from nomadism. Next military conquest, and, thirdly, military colonisation, to which the system of marches instituted by Charlemagne is closely related. A further class of migrations consists of the flight of families and individuals from a conqueror or invader. Peaceful migrations may consist of a peaceful penetration, usually mercantile, by land or sea, such as gave rise to Syracuse and Carthage. Permanent trans-oceanic migration is exclusively a feature of modern times. Temporary and seasonal migrations, though falling within the class of pacific migrations, have contributed nothing to the formation of peoples, as those who take part in them return to their own countries when once their object has been accomplished. Peaceful migrations are of more importance than the warlike, as is borne out by the fact that 250,000 Austrians landed in the United States in 1909–1910, as against 200,000 Wisigoths who crossed the Danube in A.D. 376.

ARABIC NUMERALS.—Dr. Karl Mischke, in an article in *Der Stein der Weisen*, Heft 14, in discussing the origin of the Arabic numerals, points out that the Roman numerals from 1 to 10 originated from the primitive custom of reckoning on the fingers of the two hands, and that it would be natural to assign the Arabic numerals to a similar origin. The Indian numerals do not at first sight appear to throw any light on the problem, but a comparison of archaic Indian forms found in early inscriptions with Chinese figures, which show less divergence from their original form, does suggest a derivation similar to that of the Roman numerals. Whereas, however, the Roman figures are based upon the fingers held in an upright position, in the archaic Indian and Chinese script they are regarded as held horizontally, one, two, and three being represented by a corresponding number of horizontal strokes, four by the clenched hand with the fingers held vertically, the back being towards the observer, and five by a side view of the clenched hand with the thumb uppermost. The remaining digits are formed on the analogy of the Roman numerals, $5+1$, $5+2$, and $5+5=10$, eight, however, being two fours, and nine, ten minus one. The rapidity in execution possible when a pen is substituted for the Chinese brush is responsible for the curved form of the 2, 3, 8, and 9 in the Indian script, while the Chinese retains an angular or only slightly curved form.

YELLOW FEVER IN NORTHERN BRAZIL.—While there was no reason to regard the yellow fever of Brazil as different from yellow fever occurring elsewhere, the micro-organism isolated from cases of the disease in Ecuador, Peru, and Mexico had not been experimentally demonstrated as the cause of Brazilian yellow fever. Indeed, two commissions, in 1919 and 1921, had failed to isolate the *Leptospira icteroides* from several cases studied in Bahia. A joint commission of American and Brazilian workers, therefore, proceeded to investigate the disease in Bahia in the latter part of 1923 and early part of 1924 (Hideyo Noguchi *et al.* in Monographs of the Rockefeller Institute for Medical Research, No. 20, August 1924). The commission succeeded in isolating two strains of Leptospira from two out of nine cases of yellow fever investigated, and these were proved by serological and other tests to be identical with the strains isolated elsewhere.

THE HAIR TRACTS OF MAMMALS.—Prof. F. Wood Jones (*Jour. Anat.*, vol. lix. pt. 1, pp. 72-82) puts forward some interesting views of the causation of hair tracts in mammals, including man. While not denying the efficacy of other theories on the question to account in part for the facts observed, he is of opinion that the most potent cause in the production of hair tracts is the animal's own peculiarities in the method of conducting the toilet of its coat. He bases his conclusions on the study of the habits of living marsupials and an examination of the tracts in embryos. He finds that the hair tracts, particularly the reversed or abnormal ones, coincide exactly with the direction in which the hair is combed during toilet operations, and he gives some very interesting observations on the way in which these operations are conducted and the specialisation of parts of the limbs for this purpose. He finds that the hair tracts of the adult, including the reversed tracts, are clearly shown in the embryo before it is able to influence the direction by scratching, and concludes that here there is a clear case of the inheritance of acquired characters, the whole complexity of reversals, whorls, and partings having been ingrained on the coat by the cumulative effects of the toilet methods of its ancestors. In this he supports and extends the views of Dr. Walter Kidd.

GEOLOGY OF SOUTH AUSTRALIA.—In the Trans. and Proc. of the Royal Society of South Australia, xlvii., 1923, Sir Douglas Mawson contributes two papers on the geology of the South Australian Highlands, including one on the igneous rocks of the northern

Flinders Range, in which he records a further occurrence of the primeval boulder clays belonging to the series now known as Adelaidean ; they have been often regarded as Lower Cambrian, but are now generally assigned to the Upper pre-Cambrian. In a paper on part of the South Australian Highlands north of Adelaide, he confirms the discovery by Dr. E. O. Teale of another locality of Permo-Carboniferous glacial deposits. Dr. Howchin describes the sections along the eastern side of the Gulf of St. Vincent and accepts the view that the chief fossiliferous beds are Miocene, and not Eocene as held by Tate ; he shows that the Miocene has been extensively faulted and is covered unconformably by the Pliocene.

STATISTICS OF OIL PRODUCTION.—Some interesting figures emerge from a perusal of a statistical report on petroleum production prepared by G. B. Richardson and others as a chapter of the Mineral Resources of the United States for 1922, issued last July. Up to the end of that year, the world's cumulative output of petroleum, reckoning from 1859 when Drake drilled his now classical oil-well in Pennsylvania, amounted to more than ten billion barrels. Of this colossal total, three countries together have contributed 90 per cent., namely, the United States (62·3), Russia (19·0), and Mexico (8·8). In the year under review the highest single year's output was obtained, 858,715,000 barrels constituting the world's production, this figure representing a 12 per cent. increase over the previous year (1921) and incidentally double the amount produced in 1914. During 1922 the United States produced nearly 560 million barrels of oil, due to the extraordinary flush output of the great fields of the Los Angeles Basin, California, those of the Mid-Continent and of the Gulf Coast regions ; an increase of 18 per cent. over that country's production in 1921, this figure represented 65 per cent. of the world's total production for the same year, and 8 per cent. of the world's cumulative output since 1859. These figures throw a flood of light on the economic position of the industry during the years 1922 and 1923, which together have proved a period of extravagant over-production of petroleum resulting in a widespread slump in commercial activity, a serious depression from which the industry is only just showing signs of recovery. There is reason to believe that the figures for 1923, now just becoming available from authoritative sources, will eclipse those of 1922 ; these two years may well represent the peak of the world's production of oil, so that there is some ground for anticipating a gradual decline ultimately traceable from the current year. The other feature of 1922 worthy of note to British oil interests is that this was the year when Persia, by an output of 22,247,000 barrels, rose to fourth place on the list of producing countries ; India came seventh with 8,529,000 barrels, Sarawak eleventh with 2,849,000 barrels, Trinidad next with 2,445,000 barrels, Canada nineteenth with 179,000 barrels, and England last with 1000 barrels. Finally, in this year the United States exported 136,000 barrels of domestic crude oil (not refined products) to England, and 361,000 barrels to Germany ; the major export of crude oil went to Canada, which received 8,194,000 barrels.

HUMIDITY IN THE NETHERLAND INDIES.—In Verh. No. 8, vol. i., part 6 of the Publications of the Royal Magnetic and Meteorological Observatory of Batavia are published valuable results on relative humidity, tension of vapour, evaporation, and fog, discussed under the direction of Dr. C. Braak. The Dutch text gives much valuable data in considerable detail, and there is a brief English summary. At stations having no well-developed dry season, the mean monthly values of humidity range generally between 85 and 90 per cent. Relatively low monthly values occur at stations which have a well-developed dry season ; the lowest monthly means occur mostly in September and range from 67 to 70 per cent. There is a great difference in the humidities at the high mountains of Java and those of Sumatra. The stations at the latter have a wet climate during the whole year, the lowest monthly average on Mt. Singgàlang, in May, being 87 per cent., a value 17 per cent. above that on Mt. Pangerango in July. Considerable value is attached to wet bulb temperatures, and in Batavia when the wet bulb reading exceeds 26° C. the heat becomes troublesome. Evaporation is naturally much higher in the day than in the night ; at many stations it is more than ten times as great, as a result of the relatively high wind velocity and the relatively low humidity. A chapter is given on dew and morning fog, and during prolonged drought dew is said to compensate partly for deficient rainfall. Dense haziness occurs in abnormally dry years, and in the eastern part of the Archipelago dense fog is sometimes experienced ; 1902 is especially mentioned for the worst fog for thirty years. The fog was dry and the nights were without dew ; on the east coast of Borneo high trees were not visible at a greater distance than 20 metres ; dust is supposed to have taken some part in the phenomenon.

WHY WIRELESS WAVES BEND ROUND THE EARTH.—In the December issue of the *Philosophical Magazine*, Sir Joseph Larmor explains the bending of wireless waves round the earth as due to the presence in the upper atmosphere of electrons or light ions produced by the intense ultra-violet solar radiation (see also NATURE, November 1, p. 650). Such ions would increase the speed of propagation of wireless waves by an amount proportional to their number per c.c. and to the square of the wave-length of the waves. To provide the necessary curvature of the path of the radiation round the earth, only about 500 ions per c.c. out of the 10^{15} molecules per c.c. still present at a height of 50 miles from the earth's surface are necessary. Absorption of the radiation would take place at low altitudes owing to the presence of gas molecules, and in the upper regions according to the number of ions per c.c. There would be a layer in the upper atmosphere through which radiation would be transmitted with little absorption, and the energy shed down to the earth from this layer would allow the signals to be received at the surface.

CONTACT ELECTRICITY.—Messrs. A. Coehn and A. Cuss, in the *Zeitschrift für Physik* of October 28, describe a series of experiments to determine the charges produced by contact between metals and dielectrics, in a high vacuum. They show that by heating the substances employed, so as to drive off all moisture and adsorbed gas, the results can be reproduced with certainty, and that the charge depends (*a*) on the nature of the metal, its position in the Volta series, that is to say, its tendency to give off electrons ; (*b*) on the power of the dielectric to take up positive metal ions. Mercury and the amalgams of the "noble" metals were charged positively in contact with all the dielectrics examined, which included diamond, quartz fused and crystalline, "felsenglas," sodium glass, ebonite, sealing-wax and amber. The amalgams of other metals were charged positively at low concentrations, the charge diminishing to zero as the amount of metal in the amalgam increased. For definite concentrations which differed for different dielectrics, the charges of the amalgams became negative, increasing as the amount of metal in the amalgam increased. With

diamond, even the amalgams of the alkali metals were positively charged for all concentrations. This implies that diamond in no circumstances takes up positive metallic ions.

DENDRITIC STRUCTURES IN CARBON STEELS.—In a cast steel, the elongation, reduction of area, and angle of bending are always smaller than in forged steel of the same composition. The material is rather brittle and will not resist an impulsive force. These defects are generally considered to be due mainly to the dendritic structure, which reveals itself by macro etching. The removal of this structure is an important process in the treatment of steel. It is usually done by forging and annealing, and therefore a considerably larger size of ingot is required than that actually used. If, however, the dendritic structure could be removed by a simple process of heat treatment, this would be a great benefit to the metallurgical world. The question has been investigated by Mr. Torajirô Ishiwara in a paper entitled "The Effect of Impurities on the Dendritic Structure in Carbon Steels and their Diffusion at High Temperatures" (Science Reports, Tohoku Imperial University, Series I. vol. xii. No. 4). He finds that the dendritic structure in ordinary carbon steel ingots is effaced at 100° or 200° below the liquidus line. This treatment, however, would spoil the material, since it would be badly overheated. It would appear, therefore, that mechanical work is really necessary. The author has found that quick cooling in the solidification interval favours the formation of dendrites in a steel ingot, and that carbon affects the crystallisation very little. Phosphorus has the most powerful effect of the other elements usually present, and, to a less extent, silicon and manganese. The minimum concentrations of these elements which make the ingots dendritic are nearly equal to the maximum amounts actually present in ordinary steels.

DIRECTION-FINDING BY RADIO. — The Radio Research Board is making an elaborate study of the variations of the apparent bearings of radio transmitting stations as determined by well-known radio methods of direction-finding. An account has recently been issued of the experiments which were carried out for the Board extending from February 1921 to March 1922. (Department of Scientific and Industrial Research: Radio Research Board. Special Report No. 2: Variations of apparent Bearings of Radio Transmitting Stations. Part 1: Observations on Fixed Stations, February 1921–March 1922. By Dr. R. L. Smith-Rose. Pp. x+96. (London: H.M. Stationery Office, 1924.) 3*s*. 6*d*. net.) A number of directional radio receiving sets were erected at universities or Government experimental stations in Britain. The sites chosen were on flat open ground, and so far as possible trees, metal work, and overhead wires were avoided. Regular observations were taken of the radio bearings of many transmitting stations, chiefly in Europe, the positions of which were accurately known. Many thousands of observations were taken, and Dr. R. L. Smith-Rose has summarised the results. Unfortunately, no very definite results beyond those which are already known can be deduced. While extreme variations exceeding 60° were observed when determining the direction of Moscow from Aberdeen, a distance of 1500 miles, almost equally large extreme variations were observed when determining from Bristol the direction of Poldhu. In all cases the variations were worst at night. The experiments were mostly confined to long waves having a range from 2000 to 9000 metres. In most cases also they passed over considerable tracts of land in some portion of their path. In an introduction, Mr. F. E. Smith points out that in the latter half of 1922 the investigation was extended to the comparatively short 450 metre wave which is used at present for commercial direction finding in Great Britain. It was possible with this wave-length to make experiments with waves that had passed entirely over sea. Under these conditions, comparatively satisfactory results were obtained at distances up to 100 miles, the maximum error being only a few degrees. We are looking forward with great interest to the further account of the experiments on short waves.

HYVAC OIL PUMP.—The Hyvac Two-stage Rotary Oil Pump (sold by W. Edwards and Co., 8a Allendale Road, Denmark Hill, S.E.5), in common with other rotary oil and "box" pumps, consists essentially of an eccentric steel cylinder rotating about a horizontal axis within a tank filled with oil of low vapour pressure. The inlet and outlet openings are close together, one on each side of a single sliding steel vane which moves in the cast-iron pump casing, and, by means of a spring, is caused to bear continuously against the outer surface of the inner cylinder. The latter in its eccentric motion serves to trap and expel a "parcel" of air in each revolution. The oil is sufficient to prevent leakage into the high vacuum. Two such units are mounted side by side on the same shaft and are connected in series—an arrangement which enables the pump to operate directly from atmospheric pressure down to pressures of the order of 1/1000 mm. mercury. The pump, which is American in origin, is small in size and readily portable. It is relatively silent in working, a feature appreciated by most workers with "box" pumps. The Hyvac pump, which marks, in our opinion, a real advance, is very suitable for furnishing a fore-vacuum for mercury vapour pumps. For its size it is rapid in action. Small discharge tubes can be exhausted in a few minutes, while in a test we find that so large a volume as 16 litres can be reduced from atmospheric pressure to 1/10 mm. in 30 minutes. The usual precautions must be taken. The oil must not be contaminated by water or organic vapours, or the performance will suffer. The gland about the main shaft may need very occasional attention, and the small leather non-return valve in the outlet of the first-stage unit should be renewed from time to time if the efficiency is to be maintained and if excessive leaking back of oil into the trap provided is to be avoided. If the driving belt from the motor (which is of slow speed and preferably English) is not kept tight, slipping may occur when starting up against atmospheric pressure.

BLUE ADSORPTION COMPOUNDS OF IODINE.—G. Barger and F. J. Eaton have carried the research on the blue adsorption compounds of iodine a stage further in a paper published in the Jour. Chem. Soc. for November. The constitutive and ionic influences on the formation of the various blue addition compounds with iodine are discussed. Substances having crossed conjugated double bonds (*e.g.* γ-pyrones) offer some of the best examples of the reaction; but it is now shown that many derivatives of 1 : 3 diketohydrindene do not react with iodine. The presence of a crossed conjugated double bond is not enough to ensure adsorption of iodine. The same remark applies to the bridge oxygen atom. The effect of hydrogen ion concentration on the adsorption is investigated by carrying out the adsorption in a phosphoric acid buffer solution. Wide variations in concentration of the phosphate ion affect neither the rapidity of formation of the blue complex nor its intensity. The main factor influencing the adsorption is probably molecular weight; it is probably not a constitutive factor, because compounds of the most diverse constitution are capable of giving a blue adsorption complex with iodine.

Cytology and Evolution.[1]

IT is now generally accepted as a fact that in cellular animals the control of their living activities, including the repetition of parental characters, resides in that specially highly evolved protoplasm known as chromatin. It has also been for many years realised that the behaviour of the chromosomes in mitosis—particularly their accurate longitudinal division—points to the linear arrangement of the different kinds of hereditary substance along the length of the chromosome. That this theoretical conclusion was accurate has been demonstrated beyond question by Morgan and his school. It has further been demonstrated that meiosis—the halving of the number of chromosomes in the gamete—is typically brought about by parasyndesis, the coming together of the homologous chromosomes in pairs. It is also the case that the two homologous chromosomes as they come together are similarly orientated: they are never "heads and tails."

These facts appear to justify certain important general conclusions.

(1) There exists an attractive force of a specific kind between particles of chromatin in the living cell. This is indicated (*a*) by the concentration of chromatin into chromosomes, and (*b*) by the approach of the chromosomes to one another in syndesis.

(2) The intensity of this attraction can be caused to vary by conditioning factors (*a*) of an extrinsic kind, as shown by the influence of radium on the gonad nuclei of Ascaris, and (*b*) of an intrinsic kind in the life of the cell; for example, the intensity increases during the prophases (shortening of chromosomes) and dies away in later phases of mitosis so as to be overborne in the case of the daughter chromosomes by the counter-attraction towards the centrosomes. This diminution in intensity is particularly marked in such a case as the somatic nuclei of early stages in the development of *Ascaris megalocephala*, where the chromosome loses its cohesion to the extent of fragmenting into numerous small particles.

(3) The intensity of attraction varies with the degree of likeness of the chromatin particles. This is indicated (*a*) by the localised clumping of chromatin at particular spots in the length of the chromosome ("chromomeres"), (*b*) by the coming together of *homologous* chromosomes in syndesis, and (*c*) by the fact that in parasyndesis corresponding portions of the two chromosomes come together.

[1] Abstract of an address delivered by Prof. J. Graham Kerr as retiring president of the Royal Philosophical Society of Glasgow (Biological Section), on October 10, 1924.

Natural Selection.

The view is taken that variability is to be regarded merely as a special case of the instability that is an inherent characteristic of all living substance, and therefore that it does not in itself call for special explanation. The idea that the hereditary substance (genes) is exempt from this general property, and stable and unvarying, is regarded as inherently improbable. Nature selects not variations of organs or other parts but whole individuals, according to their degree of "fitness" to their environmental conditions. As every individual is on one side or other of the normal line, the whole species is in direct touch with natural selection, not merely occasional individuals possessing some conspicuous abnormality of a particular organ, and there is therefore ample material for selection to work upon. It must not be forgotten that the selection of individuals showing a particular variation in detail necessarily involves the selection and consequent exaggeration of the *tendency* to develop that particular variation. This selection and intensification of tendency to vary in a particular direction has probably great directive influence in securing the continuity of evolutionary progress along definite lines.

The criticism that natural selection accounts only for adaptive features is now of greatly diminished importance. Certain features are known now to exist by mere chance; for example, the red colour of many deep-water marine animals. The advance of knowledge is constantly enlarging the number of features recognised as adaptive. Above all, it is now being realised far more fully how the various parts of the individual are shackled together by physiological relations through the internal medium of the body and in other ways, so that a small adaptive change in one organ is liable to carry with it correlated changes in other features of the body, possibly far more conspicuous and not in themselves adaptive.

Finally, it must be remembered that evolutionary adaptation to the environment has no natural term, for the elusive environment is in a state of continuous change in relation to the organism. Evolutionary change is a function (in the mathematical sense) of environmental change. Such change occurs in the environment itself—in the non-living environment—climatic or physiographical changes, or in the living environment—changes in the local fauna or flora; or, on the other hand, the active change may be on the part of the animal itself—such as change of habits from aquatic to terrestrial or aerial, from terrestrial to arboreal, from salt-water to fresh-water.

Progress in the Geological Survey of Great Britain.

THE Summary of Progress for 1923 of the Geological Survey of Great Britain and the Museum of Practical Geology[1] opens with the report of the Advisory Board. In this report we are reminded that in 1912 a Departmental Committee on the Science Museum and Geological Museum recommended the removal of the latter to a new building to be erected at South Kensington. The matter, shelved during the War, was not reopened until, in April 1923, the roof of the Geological Museum was found to be unsafe. It became necessary to close the Museum to the public, and later on to debar inquirers from access to the Survey offices, the Library, and the Map room. We now learn from the report that, on careful consideration of the position, the Government decided after the close of 1923 to erect a new museum and offices for the Geological Survey on the site recommended by the committee. Many will feel regret that a building and a situation with so many associations should be abandoned, but the advantages of the new site are manifest. The two great geological collections, one biologically arranged and illustrating stages in the evolution of life upon the globe, the other showing the forms of life which characterised each successive period in the history of the globe, will be side by side. It is to be expected also that adequate space will be provided not only for offices and workrooms, but also for the exhibition of minerals, rocks, and fossils now stored in drawers or overcrowded in exhibition

[1] Department of Scientific and Industrial Research. Summary of Progress of the Geological Survey of Great Britain and the Museum of Practical Geology for the Year 1923; with Report of the Geological Survey Board and Report of the Director. Pp. iv+173. (London: H.M. Stationery Office, 1924.) 4s. net.

cases. An overcrowded case produces a mere sense of bewilderment, and to say that some of the cases in the Jermyn Street Museum contain twice as many specimens as they can properly exhibit, is no overstatement.

From the Director's report, we learn that nine field-units have been engaged in carrying out the programme approved for the year. In the London district, surveying proceeded in the Romford map and was commenced in the country near Marlborough. But the bulk of the summary relates to re-examination of coal-fields and their surroundings. In the Midland district, the various subdivisions of the Upper Coal Measures, including the Enville Group, have been recognised in the Coalbrookdale coal-field. The rocks examined range from pre-Cambrian to Trias. In the Yorkshire and Lancashire districts, advantage is being taken of the remapping of the Millstone Grit to examine the marine fauna, the Goniatites in particular, with the view of establishing a zonal sequence, the want of which has been much felt. The work in Lancashire has lain chiefly near Rochdale. In the Yorkshire district, the information respecting boreholes and new sinkings in the "concealed coal-field" is being kept up-to-date with the idea of preparing a new edition of the memoir on that important investigation. In Cumberland the sequence of limestones in the Lower Carboniferous Series has been established and work has been begun on the east side of the Vale of Eden. The correlation of the same limestones is being studied in Northumberland also, and the mapping of the Scremerston Series and of the Shilbottle Coal is well advanced. In Scotland, the Edge Coals of the Carboniferous Limestone Series are of scarcely less importance than those of the Coal Measures. Their examination is proceeding in Fife, the Lothians, Stirlingshire, Ayrshire, and Lanark.

Among the publications of 1923, special mention must be made of four parts of the great monograph on Carboniferous plants by the late Dr. Kidston, a work which will be of high value all the world over. The memoir on the Concealed Mesozoic Rocks of Kent is another notable contribution to palæontology, as well as to the stratigraphy of the south-east of England.

Two remarkable maps, issued, among others, during the same year, are of the highest interest to all geologists. One, of the Assynt district, is a special map made up of parts of the four one-inch sheets, 101, 102, 107, 108; the other, Sheet 44, illustrates Mull and its surroundings. To do justice to the geology without obscuring the topography was scarcely possible on so small a scale, but both maps are remarkable examples of detailed mapping and skilful mechanical reproduction.

The memoir which has been issued on the country around Flint, Hawarden, and Caergwrle[2] gives the results of a re-survey which commenced in 1910. The area described extends from the Vale of Clwyd to the peninsula of Wirral and includes the southern part of the Flintshire Coal Field. Probably in no other part of Great Britain do the Lower Carboniferous rocks show more remarkable changes than between north and south Flintshire. They have not been re-surveyed and the identity of the Millstone Grit is still in doubt, but it may be expected that the fossils, when opportunity occurs of collecting them, will throw light on the correlation, especially when taken in conjunction with the zonal work in progress in Yorkshire. The folding and faulting of the region are of high interest and complicated. A long dissertation upon them, not easy to follow, forms the subject of Chapter ii.

The district which Mr. Osborne White describes in the Memoir on the Country near Brighton and Worthing[3] has been rendered classic by the labours of Mantell, Martin, and Dixon. The formations range in age from Wealden to London Clay, and in his account of them, Mr. White has added many observations of his own to the work of previous workers. Chapter vii., dealing with the superficial deposits, is of much interest. It contains detailed accounts of the raised beach and the overlying Coombe Rock, each of which is made the subject of suggestive speculations. A word must be said for the plates. All are good, but Plate 1, in particular, gives an admirable representation of the features of a broad landscape.

Research in Optics.

THE volume referred to below[1] contains a number of papers first published during the years 1921 and 1922 by the staff of the Optics Division of the National Physical Laboratory. They have already appeared separately in the publications of various societies and elsewhere, to which reference must be made for the several discussions. A casual reader would be likely to comment upon the diversity of the subjects which are dealt with, but doubtless this is to be explained as the result of the numerous problems which arose during the War. In spite of this diversity, the volume embodies several theoretical papers of considerable value which have received notice in the newer editions of the well-known books of Southall, Czapski, and others. Amongst these may be instanced the discussion of the classification of optical instruments (No. xvii.).

The experimental side of the work is also well represented. It is instructive to notice how the "principle of substitution" can be applied in refractometry, goniometry, and curvature measurements, for the enhancement of the accuracy of measurements, and though in many cases the methods described are available for use only in a highly equipped laboratory where measurements of precision are required, yet such methods as that described in the paper on the photometry of optical instruments should find a place in the practice of every optical workshop.

A brief notice such as the present is not the place for detailed criticism of papers the majority of which have been already discussed. Nevertheless, there are papers which only seem to point the way to a very much fuller treatment of the subject. In a paper on the position of best focus in the presence of spherical aberration, it is stated to be erroneous to suppose that "geometrical reasoning leads in a number of important practical problems to conclusions at variance with those which would be deduced directly from a wave theory of light propagation." The paper goes on to show that in the presence of simple spherical aberration, the points of greatest

[1] "The National Physical Laboratory. Collected Researches." Vol. 17. 1922. Pp. v+353. (London: H.M. Stationery Office, 1922.) 17s. 6d. net.

axial intensity of light (deduced by the wave theory on the basis of least variation of phase, and by a corpuscular or ray theory on the basis of the centre of gravity of axial ray intersections) would agree as estimated by these two theories. The paper does not show, however, that the point of greatest axial intensity is necessarily taken as the best focus when visual or photographic observation is made, and indeed nothing but experiment can settle such a question. Further, the "best focus" in geometrical optics has been universally assumed to be coincident with the circle of least confusion, which is far from the point of greatest axial intensity when spherical aberration is present. In fact, the present writer's experience has been that the statement quoted above is by no means so erroneous as the author of the paper referred to believes. There are many such questions in optics which cannot be settled by a short mathematical or geometrical discussion, and the paper thus indicates the necessity of a very much wider inquiry.

There is no doubt that the writers of these papers will face many problems of difficulty in the immediate future. Much is to be hoped from a collaboration of mathematician and experimenter in investigations which need the services of both. The production and use of non-spherical glass surfaces on a commercial scale for instrumental work is very largely waiting accomplishment, and there are other "major researches" quite worthy of the efforts of any workers. The staff of the National Physical Laboratory has, however, unique opportunities of getting into touch with industry, and aid will doubtless be given where it is most required.

Terrestrial Magnetism in France.

THE work referred to below[1] contains in twelve pages summaries of seismological and meteorological results at Parc St. Maur from 1915 to 1922. The remainder of the volume is devoted to terrestrial magnetism. The longest single article is one by the late M. C. Dufour, discussing the magnetic records of 1922 at the Observatory of Val Joyeux, of which he was in charge. M. Dufour's death in August 1923 is recorded with regret. Hourly values at Val Joyeux are confined to 6 h., 12 h., 18 h., and 24 h., except on the international quiet days, when all hours are included. The daily mean from the whole 24 hours and the general character are given, however, for each day. From 1921 to 1922 westerly declination, inclination, horizontal force, and vertical force all fell by 11′·1, 0′·4, 9γ, and 31γ respectively.

Papers by MM. Berthelot, Mathias, and others record the progress of the magnetic survey being prosecuted at present in France. It is explained that adequate financial provision has as yet been made only for the field-work. Mme. de Madinhac, one of the lady members of Prof. Maurain's staff, contributes a paper giving the values of the magnetic elements on January 1, 1921, in the chief places of each department of France. These are based on Angot's results for 1911, and on values of secular change derived after Angot's example from twelve observatories of Western Europe, which include Eskdalemuir, Greenwich, and Kew. A second lady member of the staff, Mlle. Homery, arrives in a similar fashion at corresponding results for North Africa, and also deals in a separate paper with results from 422 stations in Western and French Equatorial Africa. Charts for the epoch January 1, 1921, are given in each of these three papers. Even in the case of France the secular change data available do not appear altogether above suspicion, especially in the case of horizontal force and dip. M. Rohan Chabot deals with magnetic observations made during 1912–13 in an expedition to Angola and Rhodesia.

Work of a more theoretical character is represented by a calculation of the vertical electric current derived from a line integral of magnetic force round an area including the greater part of France. The direction found for the current is upwards, but the amplitude, 0·0043 ampere per square kilometre, is of the same order apparently as the probable error.

An interesting paper by M. C. E. Brazier discusses the relations between magnetic disturbance at Parc St. Maur and Val Joyeux and sunspot activity. For disturbance, use is made of an arbitrary scale due to Moureaux. The period 1884 to 1917 is divided into three 11-year periods, which are dealt with as a whole and separately. As has been found in England, disturbance shows a well-marked annual period. The spring maximum, near the end of March, exceeds the autumn maximum, which occurs early in October. At the end of the volume there are reproductions of the most disturbed curves of the year at Val Joyeux.

C. CHREE.

[1] "Annales de l'Institut de Physique du Globe de l'Université de Paris et du Bureau Central de Magnétisme terrestre," publiées par les soins de Ch. Maurain. Tome II. Quarto, pp. 146. Paris: Les Presses Universitaires de France, 1924.

Technical Education in Relation to Paper-making.

THE Board of Education has recently issued a report on technical education in England for the paper-making industry.[1] The report directs attention to the relatively small number of employees engaged in the manufacture of paper as compared with those of other trades such as engineering, textiles, iron and steel, but emphasises the point that the importance of the industry is probably enormously greater than the numbers employed would suggest, especially so where regard is paid to the uses of its products in commerce, education, and public administration.

Three points in the present development of the industry are important. These are:

(1) The development of the machines and other plant in use, so that the greater output is obtained at a less cost and a much increased speed. Up-to-date machinery is capable of producing paper such as "news," from a previously prepared pulp, in reels more than 200 in. wide, at a speed of more than 800 ft. per minute.

(2) Side by side there is a tendency towards larger mills and to the production of a particular paper for specific uses in any one mill.

(3) The gradual recognition of the aid which chemistry and engineering can render to the industry.

It would appear that the paper manufacturers of England are behind their American and continental competitors in their willingness to utilise the services of highly skilled specialists. The products of the English mills do not suffer in comparison with those of other countries, but if the future is to be secure, quality must be maintained and costs of production reduced. This can be accomplished only by attention to scientific methods and the systematic technical

[1] Board of Education: Report of H.M. Inspector on Technical Education in England for the Paper-making Industry. (London: H.M. Stationery Office, 1924.) 6d. net.

education of those engaged in the industry. The close co-operation of the engineer and chemist is essential. Encouragement is found in this direction in the formation of a technical section of the Paper-makers' Association, the aim of which is to foster the development of the industry along such lines.

Full-time courses of instruction in paper-making and allied subjects (chemistry, physics, etc.) are provided at the Manchester College of Technology. At the Battersea Polytechnic, London, such courses are also available, together with specialised instruction on the engineering side of the subject and on paper testing. Part-time courses (evening) are provided at these centres and at one or two other institutes.

The writer of the report has had the advantage of discussion with leading technologists connected with the industry, and makes recommendations concerning the further development of instruction by way of organised courses.

University and Educational Intelligence.

BIRMINGHAM.—The following doctorates have been awarded, the subjects of the theses being indicated in each case :—

D.Sc. (*Botany*), Mr. C. H. Gadd ("*Phytophthora Faberi*," and "The Swarming of Zoospores of *Phytophthora Faberi*," and other papers); (*Electrical Engineering*), Abdel Aziz Ahmed ("Theoretical and Experimental Study of the Electric Field in an Electrolytic Cell," "Variation of Magnetic Potential," "Investigation of Magnetic Leakage," and other papers). Ph.D. (*Biochemistry*), Mr. W. S. Shaw ("The Rôle of Silica and Phosphorus in Plant Growth and their Inter-Relations," and other papers); (*Civil Engineering*), Mr. H. V. Budgen ("Fatigue of Metals"); (*Electrical Engineering*), Mr. O. R. Randall ("The Behaviour of certain Semi-Conductors in Electric Circuits"); (*Metallurgy*), Mr. L. F. C. Northcott ("The Condition of Carbon in Iron").

CAMBRIDGE.—Mr. G. Stead, Clare College, has been appointed University lecturer in physics as applied to medical radiology. Dr. A. J. Copeland, Pembroke College, has been appointed assistant to the Downing professor of medicine. The Gordon Wigan Prize for research in chemistry has been awarded to E. H. Warren, Jesus College, for an investigation on "The Configuration of the Ammonium Ion."

It is of interest to note that of the eight successful candidates from the University in the last open competition for the Indian Civil Service, the top six studied mathematics or natural science in their Cambridge course.

EDINBURGH.—At the meeting of the University Court on December 15, it was decided to proceed at once with a scheme for the extension of the Department of Surgery in connexion with the grants recently received from the Rockefeller Foundation for the development of clinical teaching and research.

Dr. A. H. Freeland Barbour has made a further donation whereby the income of the Freeland Barbour Fellowship, awarded in each alternate year to the graduate in medicine who has taken a high place in anatomy, physiology, and pathology, and is judged most capable of carrying out research in midwifery or in diseases of women, will be increased from 120*l.* to 260*l.*

Approval by His Majesty in Council of the Court's Ordinance No. 45 (Foundation of the Chair of Organisation of Industry and Commerce) was intimated. This increases the number of professorships in the University to 55.

MANCHESTER.—Dr. W. H. Wood, lecturer in anatomy and tutor to the Faculty of Medicine, has resigned in consequence of his appointment to the Derby chair of anatomy in the University of Liverpool. Mr. H. G. Jordan, lecturer in mechanical engineering in the Faculty of Technology, has also resigned. Mr. Jordan has been a member of the staff of the College of Technology for forty-two years, and associated with the Faculty of Technology since its inception in 1906.

Mr. John Orr, at present Secretary to the Kent Rural Community Council, has been appointed adviser in agricultural economics under the Ministry of Agriculture and Fisheries Advisory Scheme, with the status of senior lecturer in the Faculty of Commerce and Administration and in the Department of Economics.

DR. W. R. COODE ADAMS has been appointed an assistant lecturer and demonstrator to Faraday House Electrical Engineering College.

DR. J. REILLY, Assistant State Chemist to the Irish Free State, has been appointed professor of chemistry in University College, Cork (National University of Ireland), in succession to Prof. A. E. Dixon.

PROF. GERLACH of Frankfort has been invited to occupy the chair of physics at the University of Tübingen in succession to Prof. F. Paschen, who was recently appointed president of the Physikalisch Technische Reichsanstalt in Berlin.

THE chairs of mathematics and English in the University of Tasmania, Hobart, will be vacated at the end of 1925. Applications are invited for them. Particulars of the posts may be obtained from the Agent-General for Tasmania, Australia House, Strand, W.C.2. The completed forms of application must be received by the Agent-General by January 31 at latest.

A DESCRIPTIVE list of "Government publications useful to teachers" as source books has been published by the United States Bureau of Education as Bulletin, 1924, No. 23. Its object is to meet a growing demand among teachers for primary sources of information to supplement text-books. The demand is especially urgent where the "project" method of instruction has been adopted. The list (34 pages, price 10 cents) is a handy guide to the publications of general interest of the United States Government—"the greatest of modern publishers."

A PRELIMINARY programme has been issued of the thirteenth annual Conference of Educational Associations to be held at University College, Gower Street, London, W.C.1, on January 1-8, under the presidency of Prof. E. A. Gardner, vice-chancellor of the University of London. The presidential address, on "Examinations: their Use and Abuse," will be delivered on the first day of the conference. Among the lectures which have been arranged are the following: "The Biology of some Common Animals," by Mr. Julian S. Huxley, on January 2; "The Measurement of Stellar Distances," by the Astronomer-Royal, on January 3; "Geography and the League of Nations," by Prof. H. J. Fleure, on January 8; "The Evidence for the Existence of Environmental Influence on the Course of Heredity," by Prof. E. W. MacBride, on January 8. Railway vouchers for return tickets for the meeting for single fare and a third can be obtained from the secretaries of the affiliated associations. A publishers' exhibition will be open in the Memorial Hall on January 2-7. The honorary organising secretary and treasurer for the conference is Miss Busk, 14 Taviton Street, W.C.1.

Early Science at the Royal Society.

December 28, 1664. Dr. Pell, upon occasion given by Sir Robert Moray, mentioned that he had at his country-house in Essex a wooden hoop, made by his directions in the year 1645, of twenty inches broad, representing the ecliptic, and at Amsterdam by Mr. Bleau lined with as much of the paper of Mr. Bleau's largest globes, as comprehends all the fixed stars within 10 deg. of the ecliptic on either side, but with the constellations inverted, as they stand in the heavens; the use of this being not only to help young observators, but also for the genuine representation of the variety appearing in the motion of the planets. He mentioned that he was willing to leave it with the Society when they shall have a fit repository to keep such instruments in.

December 29, 1686. Mr. Hooke read a further continuation of his discourse about shells, wherein he considered the structure of the nautilus, tending to prove, that though it be true, that there is no animal known resembling in all points the lineaments of those lately produced by himself; yet that it is not a sufficient argument to evince, that there is not for ever any such animal *in rerum naturâ*.

December 30, 1663. It being moved that it might be considered to make a standard of cold, it was suggested by Mr. Rooke, that this might conveniently be done by observing the degree of cold, which freezes distilled water, and by marking thereupon the expansion of the liquor in the weather-glass.—The difference of eels being discoursed of, and Mr. Henshaw mentioning the experience which the keeper of the eel-boat upon the Thames had of this sort of fish, he was desired to make what inquiry he could of that person concerning their difference, food, etc. The operator was ordered to provide some eels, and to put them into several waters, as river water, conduit water, etc., to see in which of them they will thrive best.—The business of propagating cider-fruit being again spoken of, the lord Ashley commended the red-streak, and especially the red red-streak for yielding a very rich liquor of a long duration, and for being a constant bearer. Mr. Boyle moved that some of the red-streak cider might be distilled and the spirit of it compared with wine. The lord Ashley offered a bottle for the trial.

1675. There was read a letter to Mr. Oldenburg from Mr. Newton, in answer to what had been written to him by Mr. Oldenburg concerning the want of success of his experiment made with a glass rubbed.

December 31, 1668. Dr. Wren produced a vessel contrived by himself to cure smoaking chimneys, which he affirmed had proved very effectual by divers trials. It was delivered to Mr. Hooke.

January 2, 1666/7. Mr. Hooke brought in the formerly proposed bucket for fetching up earth or any other solid body from the bottom of the sea. It was ordered, that care should be taken so to fit it, that the springs might go off both together, and that easily and certainly, and when it meets with soft ground, as well as hard; as also to grate it over.

1667/8. Mr. Panton appearing before the council, and expressing his desire for their assistance in promoting his design to establish a royal academy for educating of young gentlemen in good manners, languages, arts and sciences, and generous exercises; the council upon deliberation returned this answer, that though they well approved of this design, and were very desirous to promote it, each for himself, yet as they were a body, it was not their practice to intermeddle with any business, but such as either arose from among themselves, or came to them by way of reference.

Societies and Academies.

LONDON.

Aristotelian Society, December 1.—J. A. **Smith**: Prof. Alexander's notion of "space-time." The notion of space-time is equated by Alexander with that of pure motion. The elucidation of motion is a prime requisite for science. Alexander's aim is to help us to apprehend it immediately. Our difficulty in doing so is because we are sensitive and not purely intuitive beings. To remedy this we must endeavour to remount the stream of experience to its sources and reach a state of pure intuition. Pure motion is the simple intuition we then attain. We apprehend it not by definition but by a refinement of sensible motions and of mathematical motion. It is for science the surest and best hypothesis capable more than any other offered basis of supporting its structures.

Linnean Society, December 4.—A. B. **Rendle**: *Rafflesia Arnoldi* R. Br. and *Brugmansia Lowii* Becc., specimens sent for the British Museum by Mr. Edward Jacobson of Fort de Kock, Sumatra. They came from a forest at 800-1200 metres, near the west coast of Sumatra. Both plants are parasitic on the roots of a vine (a species of Cissus), and, except for slender threads permeating the tissue of the host, consist merely of a large flower, which in the Rafflesia measured 18 in. across.—L. J. **Wills**: The morphology of the Carboniferous scorpion, Eobuthus Fritsch. The specimen described was found near Chirk, N. Wales. It agrees fairly closely with Mr. R. I. Pocock's description of *Eobuthus holti*. The chief interest lies in the detailed structure of the chitinous test, which has been largely extracted from the shale in which it lay. The microscopic structure of the pecten can be closely matched in recent scorpions, even to the sensory papillæ. No stigmata occur on the sternites, but a thin hairy skin lies above the lobes, which no doubt protected the respiratory apparatus.—Miss V. **Hay**: Young and adult stages of *Sophora tetraptera*. Juvenile leaf-forms persist during several years on the seedlings of *Sophora tetraptera* and var. *microphylla*, and var. *prostrata*. Thus there appears to be one species with three varieties, or there may be three closely related species existing side by side under identical conditions.—Miss Violet M. **Grubb**: The development and liberation of spermatia in some undescribed cases among the Red Algæ. In *Nitophyllum Hilliæ* Grev., each antheridium mother-cell puts up in succession three beak-like protuberances, enclosed in the gelatinous extended mother cell-wall. The contents escape when ripe through an apical slit as a single spermatium clothed in a delicate wall. A similar development is found in *Callithamnion brachiatum* Bornem., where the antheridia are borne in clusters on the terminal pinnæ; secondary and tertiary antheridia grow up within the empty sheaths of the primary ones.

Royal Meteorological Society, December 17.—C. E. P. **Brooks**: The problem of mild polar climates. If there were an ice-free polar ocean just warm enough to prevent freezing at the pole and with a temperature increasing southwards at a uniform rate, and if a small decrease of temperature occurred uniformly over this ocean, a small polar ice-cap would form. If the temperature continued to fall, the growth of the ice-cap would become more and more rapid, until a point was reached beyond which the ice-cap would continue to grow without any further fall of temperature. This "critical temperature" is only about $0°{\cdot}25a$ below the freezing-point; a fall of temperature

of $0°{\cdot}25a$ would give an ice-cap with a radius of one degree of latitude, a fall of $0°{\cdot}3a$ would give an ice-cap with a radius of about 25 degrees of latitude. The "akryogenous" temperature, which the present Arctic Ocean would take up in winter if sea-water did not freeze, is about $270°a$. Hence a rise of the akryogenous winter temperature by only four or five degrees would suffice to cause a mild climate in winter. The land and sea distribution during Middle Eocene and Upper Jurassic times would give akryogenous January temperatures in latitude 75° N. of $278°{\cdot}6a$ and $280°{\cdot}8a$ respectively. Since these are well above the freezing-point they represent also the real temperatures. There is therefore a meteorological basis for mild polar climates. The Arctic Ocean has become ice-free once, possibly twice, since the Quaternary Ice Age, the second occasion falling in historic times.—Sir Napier **Shaw**: Winds and temperature in a dry atmosphere. The convection of dry air upward and downward and the distribution of temperature and potential temperature contingent thereupon would give rise to a much warmer stratosphere than the earth possesses with its present moist atmosphere. The general circulation, however, would not be different in its general character from that which prevails at present.

EDINBURGH.

Royal Society, December 8.—D. A. **Fairweather**: The electrolysis of salts of alkyloxyacids. An attempt was made to ascend the series of dibasic hydroxyacids (*i.e.* tartronic, tartaric, mucic, etc.) by electrolysis of the potassium ethyl salts of their ethylated derivatives. The products of electrolysis were of quite a different nature from those obtained in the case of the normal dibasic acids, and consisted chiefly of aldehydes; little or no synthesis took place.—W. **West** and E. B. **Ludlam**: The ionisation of iodine vapour by ultra-violet light. Iodine vapour was found to be ionised by light in the Schumann region. Quantum relations indicate that the molecule, or the fluorescing molecule, or both, may be ionised.—W. O. **Kermack** and W. T. H. **Williamson**: The stability of suspensions. I. The rate of precipitation of kaolin suspensions by salts at varying hydrogen ion concentrations. Anomalous effects in the rates of sedimentation of kaolin suspensions are observed in the cases of sodium chloride, mono-calcium phosphate, and aluminium, ferric, and lanthanum chlorides.—W. O. **Kermack** and C. I. B. **Voge**: The action of salts with multivalent cations on colloidal solutions of gold and gum benzoin. The action of solutions of ferric chloride, aluminium chloride, or lanthanum chloride in changing the charge on negatively charged colloidal particles to a positive one has been investigated more particularly in relation to the hydrogen ion concentration of the solution. The effect appears to be related to the degree of hydrolysis of the salt.—P. **MacCallum** and W. O. **Kermack**: The influence of gelatin on the stability of a colloidal solution of cholesterol and on the charge on the particles. Investigations are described on the action of solutions of gelatin at varying hydrogen ion concentrations in altering the properties of a cholesterol solution and the charge on the particles.

DUBLIN.

Royal Dublin Society, November 25.—Miss S. D. **King**: Oogenesis in *Lithobius forficatus*. Yolk formation is from nucleolar extrusion, supplemented possibly by activity of the Golgi bodies. The mitochondria are at first diffuse, later becoming concentrated. After active multiplication, which produces curious spherical mitochondrial masses, they once more become scattered through the cytoplasm. The juxta-nuclear Golgi apparatus of the young oocyte breaks up and passes out through the cytoplasm as growth proceeds.

Royal Irish Academy, December 15.—J. J. **Drumm**, N. **O'Reilly**, and H. **Ryan**: The isomeric $\alpha\alpha$ and $\alpha\gamma$ compounds of 2 : 4 : 6 : 3′ : 4′-pentamethony diphenyl propane. A synthesis of each of the above compounds is described. 2 : 4 : 6 : 3′ : 4′-Pentamethony-$\alpha\gamma$-diphenyl propane has been found to consist of colourless needles melting at 87-88° C., and to be identical with v. Kostanecki and Lampe's methylated reduction product of catechin tetramethyl ether. The above work, therefore, is in agreement with that of K. Freudenberg.

MANCHESTER.

Literary and Philosophical Society, December 16.—W. W. Haldane **Gee**: Joule's laws of electric heating. Considerable assistance was obtained in describing the early researches by the records contained in two Laboratory Notebooks in which Joule has noted his experiments. The first record relating to electric heating is dated "later end of August 1840." By October 3 in the same year Joule had completed a series of tests which enabled him to state that the heat produced by an electric current in a wire is directly proportional to its resistance, the square of the current strength and the time of its flow. He next proceeded to show that these laws applied to electrolytes. An important result of the thermo-chemical and electro-chemical determinations was a wide generalisation connecting chemical and electrical energies. A fact of historical interest in connexion with his laborious measurements was the early adoption of a unit of current strength and a unit of electrical resistance. Joule utilised his laws in an electrical method for finding specific heats. Details of his determinations are to be found in the later of the two Laboratory Books. This volume has also many records of the more accurate experiments relating to the laws of electric heating, which he submitted in a paper to the French Academy of Sciences. His calorimetric measurements were carried out to a still higher degree of perfection when in 1867 Joule showed that the value of the British Association ohm was not in agreement with his determination of the mechanical equivalent of heat. Amongst the practical outcomes of the experiments on electric heating is the process of electric welding, which Joule described in a paper in 1856 to the Manchester Literary and Philosophical Society.—J. Wilfrid **Jackson**: The occurrence of Conularia in the Carboniferous limestone of North Wales. *Conularia tenuis* was discovered in the basal beds of the Lower Brown Limestone near Dyserth. Hitherto the species has only been recorded from the Calciferous Sandstone Series at Glencartholm and Water of Leith, Edinburgh. The Dyserth Beds have been correlated with the top of the Seminula-Zone of the S.W. Province, but may be lower. They contain *Archæosigillaria vanuxemi*, which has been found in the Calciferous Sandstone Series in Scotland and at the base of the Viséan in Westmorland. The Calciferous Sandstone Series was correlated by the late Dr. R. Kidston with the Mountain Limestone of England, the overlying Carboniferous Limestone Series of Scotland being regarded as equivalent to the Yoredales of England. Dr. Kidston correlated a much higher plant-bearing horizon in N. Wales with the Calciferous Sandstone Series, namely, the Teilia Beds at the base of the Black Limestone and at least 1500 feet above the Dyserth Beds.

SHEFFIELD.

Society of Glass Technology, November 19.—Francis **Buckley**: Note on the glass-houses of the Leeds district in the seventeenth, eighteenth, and early nineteenth centuries. John Houghton, writing in 1691, stated that there were then three glass-houses in Yorkshire, one near Ferrybridge and two near Silkstone. The only glass-house actually in or near the town of Leeds in the eighteenth century was known as the Engine Glass-house, which can be traced between 1738 and 1770. The Engine Glass-house might have been the parent as well as the predecessor of the famous Hunslet Glass Works. Between 1814 and 1861, at any rate, the Bower family had several factories here. Leeds must have owed as much to this family in the nineteenth century as it did to the Fennys in the previous century. In 1883 they had four glass-houses at work, and no competition in the town itself. Just before 1850, however, there was a sudden increase in the glass concerns in Leeds and the surrounding district, especially in the neighbourhood of Castleford. An early nineteenth century glass-house at Thornhill Lees can be traced back to 1830. Here Noah Turner made flint glass until the glass-house was taken over by the Kilners in 1844, and converted into a bottle works. There was a glass-house also at Worsborough Dale prior to 1830, worked by William Usherwood, and in the year 1828 Messrs. Wood and Perkes were found in possession, making cut glass.—W. E. S. **Turner**: A striking instance of fireclay corrosion through the action of saltcake. During the emptying of a glass tank, with the gas flame still running, the fireclay blocks surrounding the dog-hole in a bottle-glass furnace began to swell and to flow soon after they became exposed to the action of the flame. When the tank was started, a charge of saltcake had probably been put into the dog-hole, under the belief that the blocking of the hole would be prevented. After examination it was found that the exposed portion of the blocks had absorbed saltcake at an early stage in the operation of the furnace, and being covered with glass and the dissociation temperature very high, the saltcake had remained unattacked, until contact with the flame during the emptying of the tank brought about decomposition.—H. S. **Houldsworth**: A note on some properties of a sandstone block after use in a glass furnace. Powdered Penshaw stone interacts as readily with a soda-lime glass as does crushed fireclay brick. Penshaw stone develops a close compact structure when used in a glass furnace. This tends to hinder the penetration of glass into the stone, thus adding to the life of the refractory, and pointing to its successful use in furnace construction.—A. **Cousen** and W. E. S. **Turner**: The production of colourless glass in tank furnaces, with special reference to the use of selenium. Pt. IV. The influence of arsenious oxide. Arsenious oxide alone is a decoloriser of glass containing small amounts of iron oxide, whilst it also suppresses the brown colour developed by selenium. Selenium and cobalt may therefore be regarded as only secondary materials in the decolorising process. An attempt to replace arsenic by its equivalent of phosphorus in the form of calcium phosphate showed the latter substance to have little or no effect upon the brown selenium colour. Antimonious oxide used instead of arsenious oxide with selenium gave a deep bluish-green colour.

PARIS.

Academy of Sciences, November 17.—M. Guillaume Bigourdan in the chair.—The president announced the death of Sir Archibald Geikie, foreign associate, and Eugène Simon, correspondant for the Section of Anatomy and Zoology.—H. **Deslandres**: A property common to spectra of different origin and structure. Preponderating action of the helium nucleus.—Maurice **Hamy**: The evolution of stars and the solar diameter.—J. B. **Senderens**: General method for the preparation of ethers. Starting with propyl, butyl, isobutyl, isoamyl, and isopropyl alcohols, the proportions of sulphuric acid and alcohol have been worked out which give maximum yields of the corresponding ethers.—D. **Mordouhay-Boltovskoy**: The transcendence of c^e and of certain other numbers.—Jules **Drach**: The problem of Tchebychew and the deformation of surfaces.—René **Garnier**: Study of the general integral of a differential system of order $2n$ round its transcendental singularities.—Paul **Lévy**: A problem of the calculus of variations.—Ragnard **Frisch**: A problem in the calculus of probabilities (the problem of Simmons).—E. **Brylinski**: The carrying away of the ether and the aberration of stars. The question as to whether the ether in the neighbourhood of the earth is or is not carried along with the earth cannot be decided by observations on the aberration of stars.—F. **Guéry**: The electric current considered as a circulation of equal charges of opposite signs. The theory of Weber is the only one at the present time in agreement with Maxwell's theory and with the hypothesis of the current being due to charges in movement in conductors.—Louis **de Broglie**: The dynamics of the light quantum and interferences.—Alb. **Colson**: The conditions of maximum solubility; the case of gypsum.—J. **Heyrovsky**: Electrolysis with the mercury drop cathode.—René **Audubert**: The photoelectric properties of the silver haloids and the mechanism of the formation of the latent image in photography.—P. **Freundler** and Mlle. Y. **Laurent**: The photochemical properties of stannous iodide.—Jean **Thibaud**: The γ-radiation of very great energy in active substances of the thorium group.—P. **Billon**: The primary β-amino-alcohols corresponding with the general formula $R.(NH_2).CH.CR_1R_2(CH_2.OH)$. The oxime of ethyl diethylacetoacetate was reduced by sodium and alcohol to the amino-alcohol, $CH_3.CH(NH_2).C(C_2H_5)_2.CH_2.OH$. The method would appear to be general.—J. **Orcel**: The determination of temperatures at which water is separated from silicates. The silicate is heated in an evacuated quartz tube by an electric furnace, and the pressure variations plotted as a function of the temperature. An example is given of the curve obtained with a sample of ripidolite (Madagascar), showing a sudden evolution of water vapour at 500°-510° C.—P. **Lebeau** and M. **Picon**: The transformation of the diamond at a high temperature *in vacuo*. In a vacuum a diamond may be exposed to a temperature of 1000° C. for twenty-four hours without change. At higher temperatures a partial change into graphite is observed. After thirty minutes' exposure to 2000° C., 10 per cent. still remained unchanged.—Jean **Jung**: The silicate enclosures of the cipolin of Saint-Philippe (Vosges, Alsace).—Jacques **de Lapparent**: The nature of the globigerina deposits in the layers between the Cretaceous and Eocene in the western Pyrenees.—Léon **Moret**: New observations on the exotic massifs of Sulens and Les Annes (Haute-Savoie).—E. **Huguenard**, A. **Magnan**, and A. **Plantol**: The variation of wind velocity with altitude near the ground.—E. **Rothé** and C. **Bois**: The earthquakes of July 10 and November 19, 1923, in the Pyrenees.—V. **Lubimenko**: The quantity of chlorophyll in the marine algæ.—L. **Plantefol**: The ecological problem for *Hypnum triquetrum*.—Armand **Dehorne**: Observa-

tion on the cells containing refractive bodies of Enchytræus (Oligochætæ). Resemblances to myelinic formations.—L. **Bounoure**: Origin of the primary gonocytes in the Triton and the signification of these elements in amphibians in general.—Denis **Bach**: The toxicity and food value of ammonium acetate for the lower fungi.— — **Pezard, Sand,** and **Caridroit**: Experimental bipartite gynandromorphism in the domestic cock. Racial recurrences governed by the autumnal moulting and the transitory character of certain pigmentary modifications.—Marc **Treillard**: The raising of *Daphnia magna* in a pure culture.—Robert **Lévy**: The mechanism of hæmolysis by scorpion poison. Comparison with other venoms.—Lucien **Cavel**: Contribution to the study of activated sludge. Very small quantities of free acid in sewage prevent nitrification and render inert the purifying properties of activated sludge.—G. **Leven**: Respiratory mechanism and treatment of serious symptoms of aerophagy.—G. **Sanarelli**: "Internal" anthrax in animals becoming carriers of anthrax spores.

SYDNEY

Linnean Society of New South Wales, October 29.—R. **Greig-Smith**: (1) The influence of certain colloids upon fermentation. Part i. Mineral colloids such as kieselguhr, kaolin, fuller's earth, silica, asbestos, as well as charcoal and agar-agar, acted as accelerating agents in hastening the fermentation of the slowly fermenting sugar, lactose, by the high temperature organism of fermenting tan-bark. Gelatinous ferric hydrate accelerated, while gelatinous aluminium hydrate retarded, the fermentation. As these are electro-positive and most other colloids are electro-negative, the electric charge had no influence under the conditions. Gelatine has no influence upon the fermentation of lactose or of itself. The precipitated phosphates of iron and alumina acted as accelerating colloids. (2) Note upon determining the hydrogen-ion concentration colorimetrically in small quantities of fluids. By using well-buffered solutions in fermentation experiments, small droplets (0·01 c.c.) may be abstracted and mixed with 0·5 c.c. of water held in the depression of a porcelain plate. On the addition of a drop of a suitable dye the active acidity can be determined, either by comparison with a drop of fluid of standardised hydrogen-ion concentration added to water in a neighbouring depression or by means of a series of coloured papers. With poorly buffered solutions dilution becomes impossible, but the plate with 0·5 c.c. of solution gives a fairly accurate picture of the acidity. Portions of agar slopes may be soaked in the 0·5 c.c. of water which soon becomes charged with the active ions and the colorimetric test can be made.—H. J. **Carter**: Australian Coleoptera. Notes and new species. No. iv. Two genera and 28 species are described as new.—G. H. **Hardy**: Australian Nemestrinidæ (Diptera). One species is described as new.

Royal Society of New South Wales, November 5.—R. H. **Cambage**: Landslides near Picton and notes on the local vegetation. The porous overlying sandstones in the locality become saturated after heavy rains and slip over the shales upon which they rest. The sandstone is calcareous, and certain trees, including the Kurrajong (*Brachychiton populneus*), seem to seek out portions of this particular sandstone formation largely because of the lime it contains. The Kurrajong avoids the more siliceous Hawkesbury Sandstone with lower lime content in the surrounding districts.

NOTICE

The issue of NATURE for next week, January 3, will contain, in the Series of **"Scientific Worthies,"** an appreciative article on the scientifc work of Prof. I. P. Pavlov, For.Mem.R.S., by Prof. E. H. Starling, F.R.S., Foulerton Professor of Physiology. It will be accompanied by a separate Photogravure Plate Portrait of Prof. Pavlov, which will be suitable for framing.

*** The number will begin a New Volume—the 115th.

Office of NATURE, St. Martin's Street, W.C.2

THE UNIVERSITY OF ADELAIDE.

MARKS LECTURESHIP IN APPLIED PHYSIOLOGY AND SHERIDAN FELLOWSHIP.

Applications are invited from graduates in Medicine for the above position.

Applicants are requested to submit testimonials, statement of academic qualifications, published researches, and a recent photograph to the VICE-CHANCELLOR, c/o Agent-General for South Australia, Australia House, Strand, London. The envelope containing the application should be marked, "Application for Marks Lectureship." Applications will not be received later than January 31, 1925.

The Lecturer will carry out his work under the general direction of the Professor of Physiology and Biochemistry. He will be required to lecture and conduct practical classes and demonstrations in Mammalian Physiology and in its applications to Clinical Medicine during two terms of approximately ten weeks each. This course will form part of the third year of the Medical curriculum. During the remainder of the academic year the incumbent will conduct research in Physiology, and may from time to time be required to furnish a report on this research to the Council of the University.

The salary will be £750 per annum. If the successful candidate is appointed from beyond the Commonwealth of Australia, the sum of £100 will be paid towards travelling expenses. The appointment will be for a fixed term of 5 years and will continue thereafter from year to year, subject to six calendar months' notice in writing on either side, given on or before June 30.

The gentleman appointed will be expected to take up his duties in Adelaide at the beginning of the second term, namely, June 1. He will not be allowed to engage in private medical or surgical practice.

Further information may be obtained from the AGENT-GENERAL FOR SOUTH AUSTRALIA, Australia House, Strand, London.

UNIVERSITY OF LONDON.—KEDDEY

FLETCHER-WARR STUDENTSHIPS.—The Senate invite applications for the KEDDEY FLETCHER-WARR STUDENTSHIPS for the promotion of post-graduate research. The Studentships, which are tenable normally for three years and are of the annual value of not less than £200, are open equally to men and women of European descent who are graduates of some British University, or have passed an examination necessary to qualify them for a Degree of some British University, but other things being equal, preference will be given to a graduate of the University of London. Applications must be received not later than January 31, 1925. Further details may be obtained on application to the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7.

TUITION BY CORRESPONDENCE

Rapid preparation by highly qualified tutors for

MATRICULATION.
Intermediate and Final B.A. and B.Sc.

Single subjects may be taken :—Latin, Greek, Hebrew, French, Mathematics, Chemistry, Logic, etc. For terms address—
Mr. J. CHARLESTON, B.A. (Hons. Oxon. & Lond.),
14 Elsham Road, Kensington, W.14.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

(DIVISION OF TROPICAL MEDICINE AND HYGIENE.)

Applications are invited for the vacant post of ASSISTANT IN HELMINTHOLOGY. Salary £500 plus superannuation under the Universities Federated Superannuation Scheme. Candidates must possess a Science Degree and a registrable qualification in Medicine or Veterinary Medicine. Applications, stating the Candidate's experience in teaching and research, with copies of his scientific contributions and the names and addresses of not more than three persons to whom reference may be made, should be received not later than January 1, 1925, by the SECRETARY, London School of Hygiene and Tropical Medicine Offices, Malet Street, London, W.C.1, from whom further particulars may be obtained.

IMPERIAL FORESTRY INSTITUTE.

FOREST ENTOMOLOGY.

Applications are invited for the post of ENTOMOLOGIST at the IMPERIAL FORESTRY INSTITUTE, UNIVERSITY OF OXFORD. Applicants should possess a thorough knowledge of Entomology in its application to Forestry. Experience of Tropical conditions is essential. The post will be tenable for four years in the first instance.

Applications, stating age, qualifications, and salary required, and furnishing references and copies of testimonials, with a list, and if possible copies, of published writings, should be submitted not later than April 15, 1925, to the SECRETARY, Imperial Forestry Institute, Oxford. Candidates should state by what date they will be prepared to take up the appointment if selected.

SWINDON AND NORTH WILTS TECHNICAL INSTITUTION.

LABORATORY ASSISTANT.

A LABORATORY ASSISTANT, age about 21 to 25, is required. Should be accustomed to the use and care of Physical and Chemical Apparatus, and be able to effect minor repairs. Commencing salary £160 per annum. Application to be made to the PRINCIPAL, Technical Institution, Swindon.

W. SEATON, Secretary.

THE UNIVERSITY OF MANCHESTER

The Council are about to appoint a LECTURER IN ANATOMY. Stipend £500 per annum. Last date for applications, February 11, 1925. Further particulars may be obtained from the INTERNAL REGISTRAR.

FOSSILS, MINERALS, ROCKS, MICRO-

SCOPE slides (rocks and botanical), lantern slides, etc. Selling collection, low prices. Mrs. GWINNELL, 34 Barrowgate Road, Chiswick, W.4.

ACCURATE CHEMICAL THERMOMETERS.

A TEXTBOOK OF GENERAL BOTANY

FOR COLLEGES AND UNIVERSITIES

By R. M. HOLMAN and W. W. ROBBINS

The authors, who have had a wide experience in several universities and agricultural colleges, maintain that the agricultural student will profit more by a broad survey of the whole field of botany; and that the general student of botany, no less than the agricultural student, will profit by having the subject related wherever possible to agricultural practices and problems. The book therefore deals with the subject from this point of view.

600 pages, with 374 illustrations.

CHAPMAN & HALL, LTD.

OXYGEN

And other Gases.

The British Oxygen Co. have works for the production of Oxygen, Nitrogen, Carbonic Acid, Nitrous Oxide, Hydrogen, and Argon in all chief industrial centres. The Company's Plants are capable of an aggregate output of **about four million cubic feet per day.**

Special Terms quoted to the Trade.

Catalogue and full particulars on application to the Head Offices of the Company—

THE BRITISH OXYGEN CO., Ltd.,
ANGEL ROAD, UPPER EDMONTON, LONDON, N.18.

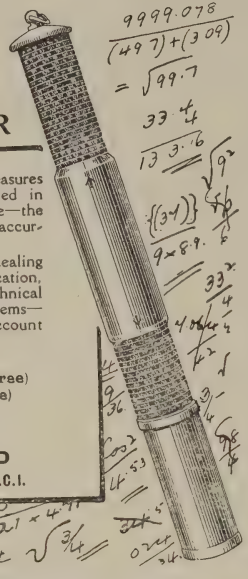
DISTILLED WATER

Brown's Stills are perfectly automatic. Can be run night and day without attention. Patented in U.K. and Continental Countries. Extraordinarily efficient and economical. Made for gas, steam, oil, or coke-fire heating.

Full particulars and prices free on application

BROWN & SON
ALEMBIC WORKS
WEDMORE ST., HOLLOWAY, LONDON, N.19.

Otis King's Patent CALCULATOR



Although the Calculator only measures 6″ when closed—and can be carried in the pocket without fear of damage—the scales are 66″ long, and give results accurate to four or five significant figures.

Model N. is of the greatest use for dealing with calculations of money—multiplication, division, percentage, etc. For technical calculations—such as engineers' problems—models K. and L. are invaluable on account of their high degree of accuracy.
